Problem 2.8 (K. Rafi). Find the asymptotic behavior for the number of conjugacy classes of pseudo-Anosov elements of the mapping class group whose translation length in the Thurston metric is less than R.

The source fixes a finite-type hyperbolic surface S, of genus g with n punctures, and its Teichmüller space $\mathcal T(S)$. The statement in the original PDF is:

The original PDF confirms the wording above. The immediately preceding text says that this question is inspired by Eskin-Mirzakhani’s count for the Teichmüller metric.

Critical exponents converge under the metric-ball subgroup exhaustion

S / solved | AIM 研讨会问题汇编

Let \(\Gamma_0\) be an infinitely generated Fuchsian group of the first kind. Denote by \(\Gamma_n\) the fundamental group carried by the \(n\)-ball in \(\mathbb H^2/\Gamma_0\).

Problem 4.4 (F. Guéritaud). Does \[\delta(\Gamma_n)\longrightarrow\delta(\Gamma_0) \qquad(n\to\infty)? \]

It says, with minor grammatical errors:

The recovered problem is:

Gu´ ertitaud” is **François Guéritaud**. Su's updated 2016 list repeats the question as Problem 5.6 with the corrected name and with “infinitely-generated.”

To make “carried” precise, choose \(x\in M:=\mathbb H^2/\Gamma_0\), let \(B_n=B_M(x,n)\), and define \[\Gamma_n :=\operatorname{im}\!\left[\pi_1(B_n,x)\longrightarrow\pi_1(M,x)\cong\Gamma_0 \right]. \tag{1.1} \] This is the standard meaning of a subgroup carried by a subset. It is also the only intrinsic meaning under which \(\Gamma_n\) is canonically a Fuchsian subgroup and \(\delta(\Gamma_n)\) is defined. No assumption that \(B_n\hookrightarrow M\) is \(\pi_1\)-injective is needed.

Open rather than closed metric balls give the same conclusion. The intended setting is torsion-free because the source speaks of a surface; the proof also works for hyperbolic orbifolds when orbifold fundamental groups are used.

Curve-orbit limits: an exact no-escape and uniqueness criterion

P / partially_solved | AIM 研讨会问题汇编

This was proposed as an "easier version" of the previous problem.

Given an (irreducible) big mapping class \(f\) and a simple closed curve \(\alpha\), do \(f^n(\alpha)\) and \(f^{-n}(\alpha)\) converge to a lamination?

The exact AIM record asks:

Source: AIM workshop *Surfaces of infinite type*, section “Classification of elements of big mapping class groups,” Problem 1.3 (AIM-TOPOLOGY-0139, source index 138).

The preceding record, Problem 1.1, supplies the workshop's provisional meaning of reducibility: a big mapping class is reducible when it preserves a possibly infinite discrete collection of pairwise disjoint essential simple closed curves and proper arcs, where discrete means no accumulation inside the surface.

1. whether curves are replaced by geodesic representatives; 2. which topology is meant by “converge”; 3. whether an empty lamination is allowed.

This report uses the standard geodesic reading made explicit by Bestvina, Fanoni, and Tao: \(S\) carries a complete first-kind hyperbolic metric \(m\) (no funnels or half-planes), each curve is replaced by its \(m\)-geodesic representative, and convergence is local Hausdorff/Chabauty--Fell convergence on finite-type compact windows. A “limit lamination” below is required to be nonempty. With the convention that the empty set is a lamination, an orbit escaping every compact set would otherwise give a vacuous affirmative example.

Direct proof of a theorem about compact funcoids

P / partially_solved | Open Problem Garden

Conjecture Let f is a T_1-separable (the same as T_2 for symmetric transitive) compact funcoid and g is a uniform space (reflexive, symmetric, and transitive endoreloid) such that $(\mathsf{\tmop{FCD}}) g = f$. Then $g = \langle f \times f \rangle^{\ast} \Delta$.

The main purpose here is to find a direct proof of this conjecture. It seems that this conjecture can be derived from the well known theorem about existence of exactly one uniformity on a compact set. But that would be what I call an indirect proof, we need a direct proof instead.

The direct proof may be constructed by correcting all errors an omissions in this draft article.

Direct proof could be better because with it we would get a little more general statement like this:

Conjecture Let f be a T_1-separable compact reflexive symmetric funcoid and g be a reloid such that

- $(\mathsf{\tmop{FCD}}) g = f$; - $g \circ g^{- 1} \sqsubseteq g$.

Then $g = \langle f \times f \rangle^{\ast} \Delta$.

Elliptic cohomology 2 - Almost everyone who has ever thought about elliptic cohomology ends up thinking it has something to do…

P / partially_solved | AMR 问题清单汇编

Almost everyone who has ever thought about elliptic cohomology ends up thinking it has something to do with 2-categories. If you think about vector bundles, you have a bunch of local trivializations, tied together by these transition functions. The transition functions must satisfy a cocycle condition--here we are thinking of a vector bundle as a locally free sheaf, or some such nonsense. I mean on U the vector bundle is U cross R^n, on V it is V cross R^n, so on U intersect V you have two different trivializations, related by a transition function. Then on U intersect V intersect W, you have three ways to trivialize and you need a cocycle condition to hold relating the three different transtion functions. One of the standard ideas for how to build elliptic cohomology is to only require the cocycle condition to hold up to natural isomorphism rather than on the nose. I believe this requires you to replace vector spaces by an appropriate 2-category. My own idea was to use the 2-category of 2-vector spaces, which I learned about in a paper by Kapranov-Voevodsky. Is this idea worth anything?

Elliptic cohomology 3 - Dennis McLaughlin and Jean-Luc Brylinski also thought along these lines.

P / partially_solved | AMR 问题清单汇编

Dennis McLaughlin and Jean-Luc Brylinski also thought along these lines. They wanted to use gerbes, or 2-gerbes maybe, instead. I could never understand what a gerbe was, but I am sure it is supposed to be a bundle of groupoids. I haven't heard anything about this for a while. Can this idea be made to go somewhere?

背景链接：https://www-users.cse.umn.edu/~tlawson/hovey/

08706 | AMR-110-0024

Elliptic cohomology 4 - Yet another idea is to go back to a decription of cobordism I once heard.

P / partially_solved | AMR 问题清单汇编

Yet another idea is to go back to a decription of cobordism I once heard. I think this description is in print somewhere, but I don't know where or who wrote it. I believe this idea is a geometric description of MU^* X. Think of X as a simplicial set. Over each vertex of X put a manifold. Over each edge of X put a bordism between the manifolds at the vertices. Over each triangle, put a bordism between the bordisms on the edges--I don't really know what these means, but orientation must be involved. Continue in this way, and that is an element of MU^* X. There must be some equivalence relation you put on these, but I don't know what it is. The problem would then be to figure out whether this works and if it has been published, then to determine how you get K-cohomology from this description--presumably the bordisms between bordisms go away, so are the identity, and this is the cocycle condition for vector bundles. Then figure out how to get elliptic cohomology.

S / solved | AMR 问题清单汇编

Currently we know how to do equivariant stable homotopy theory only when the structure group G is compact Lie. But I bet we can do it when the group G is profinite as well. The main example I am thinking of is the Morava stabilizer group, though one could warm up with the p-adics. Presumably Morava E-theory should be an object of this category, but how?

Equivariant homotopy 3 - Figure out how to do equivariant stable homotopy theory without restriction on the group.

P / partially_solved | AMR 问题清单汇编

Figure out how to do equivariant stable homotopy theory without restriction on the group. Here you are going to have to change the current setup a lot, I think. Mike Mandell has some ideas about this. He points out that a lot of the crucial problems in mathematics concern infinite discrete groups, like the Novikov conjecture, and so it may be of value to figure out this problem.

P / partially_solved | AMR 问题清单汇编

As a simpler model of the equivariant stable homotopy category, construct a derived category of Mackey functors over a Green functor, and analyze its properties. We know a lot about the derived category of a Noetherian ring--thick, localizing, and colocalizing subcategories are completely classified (See Amnon Neeman's paper on the derived category, though in my opinion you should also see Hovey-Palmieri-Strickland for simpler proofs of most of his results). Can we say analogous things about Mackey functors? Gaunce Lewis has thought about this problem a bit.

Finite quotients, genus-end filling, and coarse type

P / partially_solved | AIM 研讨会问题汇编

Let S have infinite genus and no punctures, with finitely many ends accumulated by genus. Must every homomorphism factor through an abelian subgroup? Can you forget ends accumulated by genus?

Are surfaces with infinite genus and no punctures, with finitely many ends accumulated by genus quasi-isometric?

It is, however, mathematically underspecified in four ways.

1. No codomain is given for “every homomorphism.” Literally, the identity homomorphism of a nonabelian mapping class group is an immediate counterexample. The preceding AIM records ask about finite quotients, so the likely intended reading is “every homomorphism to a finite group.” 2. The source does not say whether the domain is $\operatorname{PMap}(S)$ or $\operatorname{Map}(S)$. These readings have different answers. 3. “Factor through an abelian subgroup” is not standard wording. We read it as “factor through an abelian group (equivalently, have abelian image in the finite-quotient question).” 4. A topological surface has no canonical metric, so its quasi-isometry type is undefined until a metric is chosen. In the surrounding section, the likely object is the mapping class group with its Rosendal quasi-isometry type.

We therefore analyze the readings separately. For the most controlled family, write \[B_n=\text{the orientable boundaryless infinite-genus surface with exactly n ends, all accumulated by genus}, \] and put $G_n=\operatorname{PMap}(B_n)$ and $\widehat G_n=\operatorname{Map}(B_n)$. The phrase “no punctures” does not by itself exclude nonisolated planar ends, so results stated for B_n are explicitly a special case rather than a silent reconstruction of every possible S.

08759 | AIM-TOPOLOGY-0096

Finite-stage and filtered homotopy colimits in A-theory

P / partially_solved | AIM 研讨会问题汇编

The category of graphs with weak equivalences given by the maps inducing isomorphisms on all A-homotopy groups admits (small) homotopy colimits.

“... and allow \(n\) to depend on \(n\).”

Its exact problem statement is:

The record adds the following test problem. For a graph \(X\), \[\Sigma_nX=(X\square I_n)/{\sim}, \] where all vertices \((x,0)\) are identified and all vertices \((x,n)\) are identified. It asks, for \(n\geq 5\), whether \(\Sigma_{n+1}X\) and \(\Sigma_nX\) are weakly homotopy equivalent, even for \(n=5\) and \(X=C_5\). It then asks whether a level-collapse map \[c_{n,j}\colon \Sigma_{n+1}X\longrightarrow\Sigma_nX \] is \(m\)-connected, meaning that it induces isomorphisms on \(A_k\) for \(k\leq m\).

It still literally ends:

The most natural repair in context is “allow \(n\) to depend on \(m\),” i.e. ask whether, for every desired connectivity \(m\), sufficiently long suspensions have an \(m\)-connected collapse. The alternative repair “allow \(m\) to depend on \(n\)” asks for a connectivity estimate as a function of length. Both are mathematically sensible, and neither is silently substituted for the source.

To make “collapsing a level” precise, fix \(0\leq j\leq n\) and define \[q_{n,j}(t)= \begin{cases} t,&t\leq j,\\ t-1,&t\geq j+1. \end{cases} \] This is a graph map \(I_{n+1}\to I_n\), with \(q_{n,j}(j)=q_{n,j}(j+1)\), and it induces \[c_{n,j}[x,t]=[x,q_{n,j}(t)]. \] Different choices of \(j\) are retained; no equivalence between the resulting maps is assumed.

There is a historical discrepancy worth recording. The summary does not contain the proof, while the live problem page still says that the \(n=5,C_5\) case is unknown. This report treats the workshop statement as reported progress, not as a substitute for a citable detailed proof.

08769 | AIM-TOPOLOGY-0189

Fixed-clock boundedness for cylindrical Thurston stretch rays

P / partially_solved | AIM 研讨会问题汇编

Problem 2.11. Determine when two Thurston geodesic rays stay bounded distance apart.

The sentence immediately preceding the problem says that Lenzhen and Masur had completely answered the analogous question for Teichmüller geodesic rays. Their formulation compares unit-speed rays at the same time, possibly from distinct basepoints.

There is an essential ambiguity that was absent in the Teichmüller-metric analogue. Thurston's metric is asymmetric, so “distance” may mean the forward distance, the reverse distance, or a symmetrization. Moreover, “rays” may be compared at the same clock time, after reparameterization, or only as image sets. These conventions are inequivalent, as proved below.

The original problem does not restrict to stretch rays. The proved theorem in this report concerns the substantial special class of cylindrical stretch rays on a closed oriented surface of genus at least two, with chain-recurrent complete supports, which is the setting of Théret's theorem used below.

Develop equivariant discrete homotopy theory.

Scope. Fix a finite group G and work with finite posets carrying a left G-action by order automorphisms. Morphisms are equivariant monotone maps. Homotopies are finite fences of pointwise comparable equivariant maps.

08788 | AMR-115-0016

Foliations and Diffeomorphism Groups - Question 16

O / open | AMR 问题清单汇编

Let ω be a volume-form on $**S**^2$ and $\mathrm{Diff}_0(**S**^2, \mathrm{vol})$ be the group of volume-preserving diffeomorphisms of the 2-sphere that are in the same component as the identity map. The isomorphism type of the group $\mathrm{Diff}_0(**S**^2, \mathrm{vol})$ does not depend on the choice of ω. Banyaga [banyaga1978structure] showed that $\mathrm{Diff}_0(**S**^2, \mathrm{vol})$ is a simple group. Ghys and Gambaudo [gambaudo2004commutators] showed that there are plenty of non-trivial quasimorphisms on the group $\mathrm{Diff}_0(**S**^2, \mathrm{vol})$, in particular this group is not uniformly perfect. The following question is posed by Burago, Ivanov, and Poltervoich [burago2008conjugation].

- Is $\mathrm{Diff}_0(**S**^3, \mathrm{vol})$ uniformly perfect?

- Does $\mathrm{Diff}_0(**S**^3, \mathrm{vol})$ admit any non-trivial quasimorphism?

08793 | AMR-115-0020

Foliations and Diffeomorphism Groups - Question 20

O / open | AMR 问题清单汇编

If one drops the orderable condition, there are two constructions [skipper2019simple, belk2022twisted]. A related question of Navas [navas2018group, Question 8] was the following: does there exist a finitely generated, left-orderable group G without surjection onto $\mathbb{Z}$ and $H^2_b(G, \mathbb{R}) = 0$? The question was answered positively by Fournier-Facioa and Lodha in [fournier2023second]. In fact, the simple orderable groups of Matte Bon and Triestino are even boundedly acyclic [campagnolo2023algebraic, Corollary 1.16]. But the only known finitely presented simple orderable groups are not boundedly acyclic [hyde2023finitely, Corollary 1.7]. Thus we ask the following.

Is there a finitely presented, or even type F_∞, boundedly acyclic simple orderable group?

08801 | AMR-115-0028

Foliations and Diffeomorphism Groups - Question 28

O / open | AMR 问题清单汇编

Hirsch and Thurston [hirsch1975foliated] proved that the Euler class of amenable actions on spheres $**S**^{2n-1}$ should vanish. This is interesting because now using bounded cohomology techniques, we know a non-constructive proof that the Euler class for flat $**S**^{2n-1}$ bundles when $n>1$ is unbounded. However, by Hirsch-Thurston, it vanishes when the holonomy is amenable.

How can one explain this phenomenon that the Euler class in $H^{2n}(\mathrm{Homeo}_0(**S**^{2n-1}))$ is unbounded but it vanishes on amenable subgroups? Is it a ``hyperbolic'' class in the sense of Gromov (see [brunnbauer2024atoroidal])? Could it be that there is non-trivial bounded Euler class in $H^{2n}(\mathrm{Homeo}^{\text{vol}}_0(**S**^{2n-1}); \mathbb{R})$ where $\mathrm{Homeo}^{\text{vol}}_0(**S**^{2n-1})$ means the volume preserving homeomorphisms of the sphere $**S**^{2n-1}$?

背景链接：https://arxiv.org/abs/2503.18274

08802 | AMR-115-0029

Foliations and Diffeomorphism Groups - Question 29

O / open | AMR 问题清单汇编

In a recent work with Fournier and Monod [fournier2024bounded], we showed that in fact $\text{Homeo}_0(\mathbb{R}^n)$ is bounded acyclic for all n. Therefore, in particular, the Euler class for actions on $\mathbb{R}^{2n}$ is unbounded. But we do not know if the analog of Hirsch--Thurston still holds in these cases.

Suppose G is an amenable group acting on $\mathbb{R}^{2n}$ such that the action is at least C^1. Does the Euler class of such action vanish?

O / open | AMR 问题清单汇编

Which pairs Λ, Λ' of (possibly non-Hausdorff) simply connected 1-manifolds can be realized as the leaf spaces of a pair of transverse foliations of the plane? What if you replace "pair" by ``triple"?

One can also specialize this to the pairs of stable/unstable leaf spaces for Anosov flows, it is as yet not even known whether the stable leaf space determines the unstable.

08822 | AMR-115-0047

Foliations and Diffeomorphism Groups - Question 47

O / open | AMR 问题清单汇编

Related to the Anosov-like action conjecture, Baik-Wu-Zhao [baik2024reconstruction] recently defined a flowable group action on the bifoliated plane, and showed that if a group admits a flowable orientation-preserving action on a bifoliated plane, the group is the fundamental group of a 3-manifold with a pseudo-Anosov flow and the bifoliated plane is the orbit space of the flow. The set of axioms is slightly different, but the most important condition in both settings is the hyperbolicity (topologically expanding one leaf and contracting another leaf when two leaves cross).

Is every Anosov-like action flowable? If not, what are counterexamples and what is the precise difference between two actions?

Foliations and Diffeomorphism Groups - Question 5

O / open | AMR 问题清单汇编

Refinements of the Eliashberg--Thurston theorem by Colin and Bowden imply that any Reebless aspherical C^0-foliation approximates to such pairs. As a warm-up, one could investigate the following question raised by Colin and Firmo in [colin2011paires]:

Let (ξ_-, ξ_+) be a tight positive contact pair as in the previous question. Is M irreducible?

背景链接：https://arxiv.org/abs/2503.18274

08826 | AMR-115-0050

Foliations and Diffeomorphism Groups - Question 50

O / open | AMR 问题清单汇编

A theorem of Michel Herman says that in the group of $\mathrm{Diff}_+^\infty(**S**^1)$, every element with diophantine rotation number is C^∞ conjugate to a rotation. Using that the rotation number is a continuous function, it follows easily that every element is the product of a rotation and of a conjugate to a rotation. In particular, every element is the product of two commutators. However, it is not known if one commutator is enough.

Is every element in $\mathrm{Diff}_+^\infty(**S**^1)$ a commutator?

背景链接：https://arxiv.org/abs/2503.18274

08827 | AMR-115-0051

Foliations and Diffeomorphism Groups - Question 51

O / open | AMR 问题清单汇编

We can ask the same question, say, in $\mathrm{Diff}_0^\infty(**S**^2)$. Here is a variation on $\mathrm{Diff}_0^\infty(\Sigma_g)$, where Σ_g is surface of genus $g \geq 1$. After the work of Bowden, Hensel and Webb using their fine curve graph [bowden2022quasi], we know that the stable commutator length is unbounded on these groups.

Can we find $f \in \mathrm{Diff}_0^\infty(\Sigma_g)$ such that $\mathrm{scl}(f) = 0$ but f is not a commutator? What about $\mathrm{Homeo}_0(\Sigma_g)$?

背景链接：https://arxiv.org/abs/2503.18274

08828 | AMR-115-0052

Foliations and Diffeomorphism Groups - Question 52

O / open | AMR 问题清单汇编

Likewise, on these groups we may define the *flow length* as the word length for the set $\mathcal{S}$ of all time one map of flows, which generates $\mathrm{Homeo}_0(M)$ or $\mathrm{Diff}_0^\infty(M)$ since these groups are simple. This norm (or its asymptotic version) measures in some sense the dynamical complexity of a map, especially on surfaces where flows are considered to have ``simple" dynamics. The methods used in [bowden2022quasi] for finding elements with positive scl also yield positive stable flow length. Also note that an element which is conjugate to its inverse has vanishing scl.

Can we find an element in $\mathrm{Homeo}_0(\Sigma_g)$ with vanishing scl and positive stable flow length? Does there exist such an element which is conjugate to its inverse?

Foliations and Diffeomorphism Groups - Question 67

O / open | AMR 问题清单汇编

The subgroups of piecewise linear (PL for short) homeomorphisms of the line have been a rich source for interesting finitely generated groups with surprising algebraic and dynamical properties. However, not much is known about the algebraic properties of the PL homeomorphisms of higher dimensional PL manifolds. Although they are more combinatorial in nature, the analytical tools for diffeomorphism groups and the Mather infinite repetition trick for homeomorphisms are not available for PL homeomorphisms. So the following basic question due to Epstein [epstein1970simplicity] is still open.

(Epstein) Let M be a PL manifold. Is $\mathrm{PL}_0(M)$, the group of PL homeomorphisms of M that are isotopic to the identity, a simple group?

背景链接：https://arxiv.org/abs/2503.18274

08845 | AMR-115-0068

Foliations and Diffeomorphism Groups - Question 68

O / open | AMR 问题清单汇编

It is likely that using Bowden-Hensel-Webb's work, one could show that ${\textnormal{\text{PL}}}_\circ(\Sigma,\text{rel }\partial)$ is not uniformly perfect for cases where $\text{Homeo}_0(\Sigma,\text{rel }\partial)$ is not uniformly perfect. This gives an h-principle approach for perfectness of ${\textnormal{\text{PL}}}_\circ(\Sigma,\text{rel }\partial)$. I still do not know an algebraic proof and more importantly do not know how to generalize my approach to higher dimensions. In particular, I do not know the following.

Is the space $\overline{\mathrm{B}\Gamma}_n^{\textnormal{\text{PL}}}$ is $n+1$-connected?

Foliations and Diffeomorphism Groups - Question 70

O / open | AMR 问题清单汇编

Also, it is tempting to think about the analog of Milnor's conjecture for PL homeomorphisms. Recall that for a finite dimensional Lie group G, Milnor conjectured that \[H_*(BG^{\delta}; \mathbb{F}_p)\to H_*(BG; \mathbb{F}_p) \] is an isomorphism in all degrees. Here, $\mathbb{F}_p$ is the finite field with p elements, BG is the classifying space of the Lie group G and BG^{δ} is the classifying space of G made discrete. The work of Greenberg on PL foliations seems to suggest that the classifying space of PL Haefliger structures is inductively built out of classifying spaces of Lie groups made discrete. So it might be reasonable to expect the following.

Is the map \[H_*(B\mathrm{PL}(M)^{\delta}; \mathbb{F}_p)\to H_*(B\mathrm{PL}(M); \mathbb{F}_p) \] an isomorphism in all degrees?

Foliations and Diffeomorphism Groups - Question 9

O / open | AMR 问题清单汇编

The group of Engel automorphisms of the local model is very rich: it is isomorphic to the group of contactomorphisms of standard tight $\mathbb{R}^3$. However, automorphisms do not globalize (we cannot ``cut them off''). In fact, it is known, due to work of R. Montgomery, that there are Engel manifolds with very small automorphism group. He posed the question of whether there exists an Engel manifold with trivial automorphism group. One such example was recently found by Koji Yamazaki, but the ambient manifold is non-compact. The following question remains open:

Is there a closed Engel manifold with trivial automorphism group?

Forgetting full flags and the local geometry of parabolic braid varieties

P / partially_solved | AIM 研讨会问题汇编

Relate ordinary braid varieties built from complete flags in G/B to parabolic (or “singular,” in the singular-Soergel sense) braid varieties built from partial flags in G/P.

It is item 6.3 in the section “Braid varieties” of the 2023 AIM workshop *Algebra, geometry, and combinatorics of link homology*. The record gives no definition of “singular braid varieties.” The live problem-list endpoint returned an internal error on 2026-08-13.

The official workshop report removes much of the ambiguity. Its corresponding working group is titled **Parabolic braid varieties** and says that the group defined a parabolic analogue of braid varieties, proved its affineness, and verified that every parabolic Richardson variety is a special case. Smoothness, Deodhar decompositions, and cluster structures were left as future directions. Thus the best-supported reading is:

This terminology must be separated from two other readings:

1. a **scheme-singular closure** of a smooth ordinary braid variety; and 2. the **singular braid monoid** from classical knot theory.

No evidence was found that item 6.3 uses the second meaning. Scheme singularities do arise after taking orbit/Richardson closures and projections, but “singular” in the workshop context primarily means parabolic or nonregular.

Fundamental groups under quasi- and almost-positive curvature

P / partially_solved | AIM 研讨会问题汇编

Problem 46. Find new examples of fundamental groups in quasi-positive curvature or positive curvature on an open dense set.

The section heading at lines 140--141 is “Quasi-positive Curvature and Positive Curvature on an Open Dense Set.” Problem 45 asks about homogeneous quotients immediately before it, and Problem 47 asks a stabilization/symmetry question immediately after it. Thus “positive curvature on an open dense set” has the standard pointwise meaning used in the literature, not merely positivity for an open dense subset of the Grassmann bundle.

For a Riemannian manifold \((M,g)\), define \[\mathcal P(g)=\{p\in M:\sec_g(\sigma)>0 \text{ for every }2\text{-plane }\sigma\subset T_pM\}. \] The metric is **quasi-positively curved** if \(\sec_g\geq0\) and \(\mathcal P(g)\neq\varnothing\). It is **almost positively curved** (the modern name for the second condition in the problem) if \(\sec_g\geq0\) and \(\mathcal P(g)\) is open and dense. Openness is automatic from continuity of sectional curvature and compactness of the Grassmannian of two-planes at a point; density is the extra hypothesis. Almost-positive curvature implies quasi-positive curvature.

Hausdorff noncomputability and a certified punctured-torus classifier

P / partially_solved | AIM 研讨会问题汇编

Problem 2.1. Is there an algorithm to find the maximally stretch lamination?

The long row of dots after the question is a printed separator. The following sentence, “Generically, a Thurston geodesic connecting two points in Teichmüller space is not unique,” introduces the envelope question numbered 2.2; it is not part of Problem 2.1.

The implicit input is a pair of marked hyperbolic structures (X,Y) on a finite-type surface (S). The source does not specify either a representation of (X,Y) or a representation of the requested lamination. That omission is mathematically decisive: exact symbolic input, approximate numerical input, and a promised generic stratum lead to different algorithmic questions.

08915 | AIM-TOPOLOGY-0272

Holomorphic monodromy as a Teichmüller-section problem and finite-cover defect

P / partially_solved | AIM 研讨会问题汇编

Question 3.1 (Dieter Kotschick). Fix a closed Riemann surface \(B\) of genus \(g\geq 3\), and fix \(h\geq 2\). There exist at most finitely many non-isotrivial holomorphic genus \(h\) fibrations over \(B\), \[F_h\longrightarrow X\longrightarrow B. \] This gives a conjugacy class of representations \[\rho:\pi_1(B)\longrightarrow \operatorname{MCG}(F_h). \] How to characterise the representations which are the holonomy of a holomorphic fibration?

Comment 3.2 (Dieter Kotschick). When the fibration is holomorphic there is a Kähler structure on the surface bundle \(X\), and so the cohomology of \(X\) satisfies certain constraints from Hodge theory (e.g. \(h_1(X)\) is even). These constraints give some restrictions on the representations, but they are not enough to give an “if and only if” statement.

The recovered typography repairs \(Fh\) to \(F_h\), adds the missing space after “\(B\).”, joins the line-break hyphenations “charac-terise” and “struc-ture,” and restores “Kähler.” The source displays \(h_1(X)\); it is the first Betti number in this context.

The intended fibration is a proper holomorphic submersion with connected smooth genus-\(h\) fibers. Ehresmann's theorem then makes it a smooth surface bundle. This is not a singular fibration: if critical values \(D\subset B\) are allowed, geometric monodromy is naturally a representation of \(\pi_1(B\setminus D)\), with additional local monodromy data. Nor does “holomorphic fibration” mean holomorphically locally trivial; a non-isotrivial Kodaira fibration is smoothly locally trivial but its fiber complex structure varies.

Horofunction drift obstructs recurrence and finite invariant measure for the marked harmonic-stretch flow

P / partially_solved | AIM 研讨会问题汇编

Problem 2.7 (K. Rafi). Define the geodesic flow for the Thurston metric and study its properties, such as ergodic or mixing.

The exact mathematical question in the source PDF is:

Inspection of the PDF and neighboring records shows that this sentence introduces Problem 2.8, the counting problem for pseudo-Anosov conjugacy classes; it is not part of Problem 2.7. The contextual paragraph immediately before Problem 2.7 compares the desired theory with the Teichmüller geodesic flow on moduli space.

This report treats the recovered one-sentence question above. It distinguishes:

1. a selected-ray flow on marked Teichmüller space; 2. the induced flow on the diagonal mapping-class quotient; and 3. the impossible stronger request for a canonical flow containing every Thurston geodesic direction without an additional selection rule.

Kirby Problem 1.12

P / partially_solved | Kirby 低维拓扑问题

This problem presents several variations on the Cosmetic Surgery Conjecture, discussed in turn below. (a) $($ Cosmetic Surgery Conjecture $)$ Two surgeries along inequivalent slopes are never purely cosmetic. (b) $($ Oriented knot complement conjecture $)$ If K_{1} and K_{2} are knots in a closed, oriented 3-manifold N whose complements are homeomorphic via an orientation-preserving homeomorphism, then there exists a homeomorphism of N tak- ing K_{1} to K_{2}. (c) Let $K \subset S^{3}$ be a nontrivial knot, then K admits no purely cosmetic surg- eries. (d) If $K \subset S^{3}$ is not the torus knot $T_{2g+1,2}$, then K admits no chirally cos- metic surgeries with inequivalent slopes.

P / partially_solved | Kirby 低维拓扑问题

(Kontsevich-Zorich conjecture). Understand the homotopy types of strata of abelian differentials. Which stratum-components are $K(\pi, 1)$ spaces? What are the fundamental groups? For which stratum-components $\mathcal{H}$ is some ver- sion of the monodromy map $\rho: \pi_{1}(\mathcal{H}) \to \operatorname{Mod}(S_{g})$ injective? Do the answers to these questions change in a predictable way as one moves from the principal stra- tum down to the minimal?

Kirby Problem 2.43

P / partially_solved | Kirby 低维拓扑问题

Let X be a compact, totally disconnected subset of $\mathbb{R}^{2}$ with $|X| \geq 2$, and let Γ_{X} denote the mapping class group of $\mathbb{R}^{2} - X$. (a) For $Y \subset X$, let $\Gamma_{X,Y}$ be the subgroup of Γ_{X} permuting Y . Classify in- variants q that are functorial. (b) If $X \subset \mathbb{R}^{2}$ is totally disconnected and α is a homeomorphism of $\mathbb{R}^{2}$ fixing X as a set, let $C_{\alpha}(X)$ denote the space of α-invariant closed subsets of

X, in the Hausdorff topology. Let q be functorial as in part (a). Classify those q that are continuous or semi-continuous. (c) What is the relationship between the translation length τ_{X} and topological entropy? More precisely, is there a positive constant C so that if α is a homeomorphism of $\mathbb{R}^{2}$ permuting X and g is the class of α in Γ_{X}, then the (topological) entropy of α is at least as big as $C \cdot \tau_{X}(g)$? (d) Suppose X is a Cantor set in the plane, and let $P\Gamma_{X}$ denote the ‘pure’ subgroup of Γ_{X} fixing X pointwise. Let N be a subgroup of $P\Gamma_{X}$ that is normal in Γ_{X}, and for each integer n, let N_{n} be the subgroup of $P\Gamma_{n}$ that is the image of N restricted to any n-element subset of X. What possible sequences of subgroups N_{n} can arise in this way? (e) For which $g \in \Gamma_{X}$ is there an embedding $X \to \mathbb{R}^{2}$ for which g is represented by a diffeomorphism α which is C^{∞}? Or C^{k} for fixed k?

Kirby Problem 5.16

P / partially_solved | Kirby 低维拓扑问题

Let R be $\Z$ or a field. Let A and B be differential graded algebras so that either: \begin{itemize}

- As a graded algebra, A (respectively B) is isomorphic to the free, non-commutative R-algebra on finitely many homogeneous generators x_{i}, i.e., to the tensor algebra on the free R-module generated by $x_{1},\ldots,x_{n}$.

- As a graded algebra, A (respectively B) is isomorphic to a free graded-commutative algebra on finitely many homogeneous generators x_{i}. (So, if the x_{i} have even gradings, A is a polynomial algebra.) \end{itemize} (Different generators can have different gradings, A and B may have different numbers of generators, and gradings of generators may be negative.)

Are the following questions decidable?

- Is A stable tame isomorphic to B?

- Is A quasi-isomorphic to B?

- Is A derived Morita equivalent to B?

Kirby Problem 5.18

P / partially_solved | Kirby 低维拓扑问题

- In higher dimensions, find the `non-analytic' cohomology module $\HH^{*}_{?}$ analogous to the analytic lattice cohomology $\HH^{*}_{\mathrm{an}}$, and a natural functor $\HH^{*}_{\mathrm{an}}\to \HH^{*}_{?}$ connecting them.

- Define a version $\ECH^{*}$ of Embedded Contact Homology for isolated complex singularity links (in any dimension) associated with the canonical contact structure of the link, together with a natural graded $\Z[U]$-module morphism $\HH^{*}_{\mathrm{an}}\to \ECH^{*}$. More precisely,

- Show that this morphism is injective.

- Fix the diffeomorphism type of a link, and also a contact structure on it that can be realized as the canonical contact structure associated with some singularity analytic structure. Then characterize the family $\{\HH^{*}_{\mathrm{an}}\}$, indexed by all the possible analytic germs inducing this contact link, via those graded sub-$\Z[U]$-modules of $\ECH^{*}$ which satisfy certain specific properties.

Kirby Problem 5.6

P / partially_solved | Kirby 低维拓扑问题

- Does every closed, PL, orientable n-manifold admit an n-fold branched covering map over S^{n}?

Assuming that the answer to this problem is "yes", the following follow-up questions would be natural to ask.

- Does every n-manifold admit an n-fold branched covering over S^{n} with branch locus a codimension-2 embedded submanifold?

- If the answer to (b) is "yes", then one could naturally ask if the cover can additionally be taken to be simple, meaning the covering monodromy sends every meridian of the embedded submanifold to a transposition. For $n=2,3,4$, the above papers show the answer is, "yes".

- If the answer to (b) is "yes", then in a separate direction one could ask when the branch locus can be taken to be orientable.

O / open | AMR 问题清单汇编

The biggest problem, in my opinion, is to come up with a specific vision of where homotopy theory should go, analogous to the Weil conjectures in algebraic geometry or the Ravenel conjectures in our field in the late 70s. You can't win the Fields Medal without a Fields Medal-winning problem; Deligne would not be DELIGNE without the Weil conjectures and Mike Hopkins would not be MIKE HOPKINS without the Ravenel conjectures. We can't all be Deligne or Mike, but making the conjectures requires different talents than proving them, and more of us might have a chance. This was actually my motivation for making this list; to provide a forum for conjectures so that we might collectively be able to form a program analogous to the Weil conjectures. This would make a huge difference to our field, I think. Of course, they have to be somewhat accessible conjectures, which the problems below may not be!

O / open | AMR 问题清单汇编

The generating hypothesis, which asserts that the stable homotopy functor is faithful on the category of finite spectra. That is, if f is a map of finite spectra such that pi_* f is 0, then f is nullhomotopic. An unbelievable consequence of this is that the stable homotopy functor is full as well. This conjecture has withstood serious attempts for many years, so be careful! The basic reference is P. Freyd, Stable homotopy, in {\it Proc. Conf. Categorical Algebra (La Jolla, Calif., 1965)}, 121--172, Springer, New York, 1966; MR {\bf 35} \#2280. Devinatz and Hopkins have a program to prove the generating hypothesis when the target is a sphere; see E. S. Devinatz, The generating hypothesis revisited, in {\it Stable and unstable homotopy (Toronto, ON, 1996)}, 73--92, Amer. Math. Soc., Providence, RI, ; CNO CMP 1 622 339.

09382 | AMR-110-0003

Major problems 3 - Find some geometric meaning for elliptic cohomology.

P / partially_solved | AMR 问题清单汇编

Find some geometric meaning for elliptic cohomology. I believe this problem may be solvable--we keep learning new things about it. One thing I will say here; if I am called to referee a paper on elliptic cohomology that does not deal with the Hopkins viewpoint on elliptic spectra, I will almost surely reject it. The time is gone when one could write papers about the Landweber-Ravenel-Stong elliptic cohomology based on the Jacobi quartic--we now understand that that is only one of many different elliptic cohomology theories, and all papers on elliptic cohomology should now accept that and deal with it. The fundamental reference here is M. J. Hopkins, Topological modular forms, the Witten genus, and the theorem of the cube, in {\it Proceedings of the International Congress of Mathematicians, Vol.\ 1, 2 (Z\"urich, 1994)}, 554--565, Birkh\"auser, Basel, 1995; MR 97i:11043. But one should also see Grojnowski's approach to equivariant elliptic cohomology--unfortunately, this does not seem to be published, but there is a preprint. Matthew Ando has also thought about this, see M. Ando, Power operations in elliptic cohomology and representations of loop groups, Trans. Amer. Math. Soc. ; CNO CMP 1 637 129. I am sure I have left something out here as well.

Minimal-area conformal metrics and a thick-part Thurston bound

P / partially_solved | AIM 研讨会问题汇编

For a fixed Riemann surface \(X\), among conformal metrics \(\rho|dz|\) such that every homotopically nontrivial closed curve \(\gamma\) has \(\ell_\rho(\gamma)\geq1\), is the infimum of area attained? Does this problem have a relation to Thurston's metric?

\[\inf_{\gamma}\ell_\rho(\gamma)\geq 1. \]

The updated version in Su's 2016 handbook chapter repeats the same question as Problem 6.5. Neither short problem-list version says in the displayed formula which curves \(\gamma\) are allowed. That missing quantifier is fixed by the cited primary source, Wolf--Zwiebach: \(\gamma\) runs through all homotopically nontrivial closed curves on the Riemann surface, with homotopy taken relative to the punctures. It is enough to impose the condition on simple closed curves. Wolf--Zwiebach normalize the lower bound to \(2\pi\); rescaling the conformal factor gives the bound \(1\) in Su's question.

Thus the recovered question is:

There is an important qualification. On a closed surface, “area” is ordinary area. On a punctured surface, the intended Wolf--Zwiebach problem uses complete metrics and a renormalized or *reduced* area. Ordinary area is necessarily infinite when peripheral curves are included; Proposition 5.1 below proves the elementary divergence and exactly recovers Wolf--Zwiebach's subtraction coefficient.

Minimal-rank locus and exact signed families for Jucys--Murphy braid closures

P / partially_solved | AIM 研讨会问题汇编

For integer exponents \(\boldsymbol\tau=(\tau_1,\ldots,\tau_n)\), compute the ordinary unreduced Khovanov homology of the planar closure of the Jucys--Murphy braid product \(\prod_j JM_j^{\tau_j}\).

The sentence is not a complete mathematical specification. It omits the functor applied to the braid, the closure, coefficients, reduction, grading normalization, the allowed exponents, and the convention for \(JM_j\).

We use \(\tau_j\) rather than \(t_j\) for braid exponents, reserving \(s\) for the homological variable. Our convention is \[JM_1=1,\qquad JM_j=\sigma_{j-1}\cdots\sigma_2\sigma_1^2 \sigma_2\cdots\sigma_{j-1}\in Br_n\quad(j\ge2). \] This is the positive multiplicative Jucys--Murphy braid used, for example, by Gorsky--Hogancamp. The \(JM_j\) are pure and commute. Let \[\beta_{\boldsymbol\tau}=\prod_{j=1}^n JM_j^{\tau_j}, \qquad L_{\boldsymbol\tau}=\widehat{\beta_{\boldsymbol\tau}}, \] with the coherent braid orientation. We use ordinary even, unreduced, integral Khovanov cohomology \(Kh^{i,j}\) in Khovanov's normalization; field coefficients are written explicitly. The exponent \(\tau_1\) is inert because \(JM_1=1\).

Mirzakhani-typical recurrence and equidistribution of classical stretch lines

P / partially_solved | AIM 研讨会问题汇编

Problem 2.10 (K. Rafi). Is a stretch line typically recurrent/dense/ equidistributed in moduli space?

Rafi. Inspection of the original PDF gives the question

First, the line break `e-quidistributed` means “equidistributed.” Second, the sentence about Lenzhen and Masur is printed after a dotted separator and introduces Problem 2.11, concerning pairs of Thurston geodesic rays; it is not part of Problem 2.10.

The source works with Teichmüller spaces of finite-type hyperbolic surfaces. The result below directly treats the closed case of genus at least two, which is the setting of the presently available ergodic stretch-flow theorem.

Miscellaneous problems 2 - Classify all possible Bousfield classes of E-infinity ring spectra.

P / partially_solved | AMR 问题清单汇编

Classify all possible Bousfield classes of E-infinity ring spectra. I know very little about this problem. Note that the Spanier-Whitehead dual of the suspension spectrum of a space X is an E-infinity ring spectrum, with multiplication dual to the diagonal map. But you are forgetting the disjoint basepoint!! When you add, as you must, a disjoint basepoint to X, you find that the E-infinity ring spectrum has the Bousfield class of the sphere. Also, I once heard somebody--Jim McClure?--say that if you start with, say, MU, and you mod out by p, you find that you must also mod out by all the higher v's too in order to get an E-infinity ring spectrum. Therefore, I conjecture that if E is an E-infinity ring spectrum that kills a nontrivial finite spectrum X, then E has the Bousfield class of E(n) for some n. (I must be p-local here). We know these Bousfield classes do occur, since Morava E-theory is an E-infinity ring spectrum. (Goerss-Hopkins).

Miscellaneous problems 3 - This one is due to Mike Hopkins.

S / solved | AMR 问题清单汇编

This one is due to Mike Hopkins. Generalize the whole Thom spectrum business as follows. Take an A-infinity ring spectrum E. Look at the space of A-infinity self equivalences of E. I think this has a classifying space B, because of composition of self equivalences. Given a map X --> B you should be able to construct a Thom spectrum, and it should be some kind of half-smash product of E and X. Mike had a more explicit description, which I seem to have forgotten.

Model categories 1 - The safest sort of problem to work on with model categories is building one of interest in applications.

S / solved | AMR 问题清单汇编

The safest sort of problem to work on with model categories is building one of interest in applications. The essential idea is: whenever someone uses the word homology, there ought to be a model category around. I like this idea a great deal, and it might lead to expansion of algebraic topology into many different areas. The simplest example that I personally do not understand is complexes of (quasi-coherent?) sheaves over a scheme. There is certainly a model structure here, and it is probably even known. But I think it would be good to find this out, and find out how the model structure is built. I believe this should be a symmetric monoidal model category. I also have the impression that one can not generalize the usual model structure on chain complexes over a ring, because you won't have projectives. But these two impressions sort of contradict each other, since the second one would lead you to generalize the injective model structure on chain complexes over a ring, but this model structure is not symmetric monoidal. So there is something for me at least to learn here.

P / partially_solved | AMR 问题清单汇编

In the appendix to my book on model categories, I said maybe what we are doing in associating to a model category its homotopy category is the wrong thing. Maybe we should be associating to a model category C the homotopy categories of all the diagram categories C^I, together with all the adjunctions induced by functors I --> J. This would make homotopy limits and colimits part of the structure. Does this viewpoint have any value?

S / solved | AMR 问题清单汇编

Given a symmetric monoidal model category C, Schwede and Shipley have given conditions under which the category of monoids in C is again a model category (with underlying fibrations and weak equivalences). On the other hand, the category of commutative monoids seems to be much more subtle. It is well-known that the category of commutative differential graded algebras over Z can not be a model category with uinderlying fibrations and weak equivalences (= homology isos). On the other hand, the solution to this is also pretty well-known--you are supposed to be using E-infinity DGAs, not commutative ones. Find a generalization of this statement. Here is how I think this should go, broken down into steps. The first step: find a model structure on the category of operads on a given model category. (Has this already been done? Charles Rezk is the person I would ask). We probably have to assume the model category is cofibrantly generated.

S / solved | AMR 问题清单汇编

Find conditions under which algebras over a noncofibrant operad admit a model structure that generalize the monoid axiom of Schwede-Shipley. This would include the case where everything is fibrant, for example. Show that, under some more conditions, a weak equivalence of operads induces a Quillen equivalence of the algebra categories. Thus, sometimes you can use commutative, sometimes you can't, but you can always use E-infinity. And using E-infinity will not hurt you when you can use commutative.

P / partially_solved | AMR 问题清单汇编

My general theory is that the category of model categories is not itself a model category, but a 2-model category. Weak equivalences of model categories are Quillen equivalences, and weak equivalences of Quillen functors are natural weak equivalences. Define a 2-model category and show the 2-category of model categories is one. Note that the homotopy 2-category at least makes sense (in a higher universe): we can just invert the Quillen equivalences and the natural weak equivalences. This localization process for an n-category has been studied by Andre Hirschowitz and Carlos Simpson in descent pour les n-champs, on xxx.

P / partially_solved | AMR 问题清单汇编

The 2-category of simplicial model categories is supposed to be (according to me) 2-Quillen equivalent to the 2-category of model categories. Even without having all the definitions one can try to find out if this is true. For example, Dan Dugger has shown that every model category (with some hypotheses--surely cofibrantly generated at least) is Quillen equivalent to a simplicial model category. Understand his result in the context of the preceding two problems. That is, does Dugger's construction in fact give a 2-functor from model categories to simplicial model categories? Does it preserve enough structure to make it clear that it will induce some kind of equivalences on the homotopy 2-categories?

Morava K- and E-theory 3 - Elucidate the connection between the Morava stabilizer groups and the K(n)-local category.

S / solved | AMR 问题清单汇编

Elucidate the connection between the Morava stabilizer groups and the K(n)-local category. The first such problem, which is certainly not very hard and is no doubt known to Hopkins and some others, is to determine the structure of E*E and L_K(n)(E_*E), where E is Morava E-theory. You can take Morava E-theory to be the K(n)-localization of E(n), or you can take it to be the one related to the Lubin-Tate moduli space. The answer is supposed to be: for E^*E, you should get the twisted completed group ring E[[S]] of the stabilizer group--recall the stabilizer group acts on E, and that is where the twisting comes in. The completion affects both E and S and is an inverse limit over open subgroups of finite index. The answer for L_K(n)(E_*E), by which I mean pi_*(L_K(n) (E smash E)), should be C(S,E), continuous functions from S to E. Part of this problem is choosing exactly which E you want to work with and defining all these terms precisely. Actually, it would be better to do this for every reasonable choice of Morava E-theory E. Neil Strickland and I could probably have done this in our memoir on the K(n)-local category, but we thought the paper was long enough. But nobody else has done it, so maybe not. Even though this is folklore, I think it would be of value to get it all straight.

P / partially_solved | AMR 问题清单汇编

As a rule, I am not happy about the arbitrary nature of some of the constructions in the K(n)-local category. Consider the spectral sequence, for example, which relates the continuous cohomology of S with coefficients in pi_*(L_K(n)(E smash X)) to pi_* L_K(n) X, for example. The usual construction of this is to take the Adams-Novikov spectral sequence for E smash X smash a type n, and then take an inverse limit. I have never liked this, and it certainly only works for dualizable X. Is there some more natural construction? I have the same objection to the more general Devinatz-Hopkins construction of fixed point spectra designed to yield a spectral sequence starting with continuous cohomology rather than discrete cohomology.

Morava K- and E-theory 6 - We now know that Morava E-theory admits an action of the stabillizer group S.

S / solved | AMR 问题清单汇编

We now know that Morava E-theory admits an action of the stabillizer group S. This is the famous Hopkins-Miller result, which one day I hope will see the light of day. Their proof relies on calculating the A_infinity automorphism group of E and showing that it is a homotopy discrete group whose pi_0 is isomorphic as an abstract group to the stabilizer group. As a method, this leaves a lot to be desired. The biggest problem here is: give a construction of Morava E-theory that makes it obvious that there is an action of the stabilizer group on it. Presumably this will require going from Lubin-Tate moduli spaces to spectra using some sort of infinite loop space technology. Note that the action should be continuous in an appropriate sense.

Normalized obstructions to pointwise quarter-pinched collapse

P / partially_solved | AIM 研讨会问题汇编

Problem 8. Is there a sequence of simply-connected, pointwise strictly \(\frac14\)-pinched manifolds \(M_i^n\), \(n>2\), that collapse?

There is a substantive ambiguity that the one-line source does not resolve. “Collapse” normally comes with a scale convention. In the bounded-curvature sense one asks for, after normalization, for example \[|\sec_{g_i}|\leq 1,\qquad \operatorname{diam}(M_i,g_i)\leq D, \] and Gromov--Hausdorff convergence to a compact space of dimension less than \(n\) (equivalently, in this setting, volume tending to zero). Problem 7 immediately before this one explicitly assumes \(|\sec|\leq1\), which is evidence that a curvature normalization was intended in Problem 8 as well. Without an upper-curvature or diameter normalization, Problem 8 has a trivial affirmative answer by homothety; this is proved below.

Open Problems in Topological Algebra - Problem 6 (Protasov)

O / open | AMR 问题清单汇编

It is well known that σ-compact topological groups have countable cellularity [Tk] while compact topological groups support a strictly positive probability measure (i.e., a Borel probability measure μ such that $\mu(U)>0$ for any nonempty open subset U of the group). Recently T. Banakh and O. Ravsky [BR] (see also [BR2]) proved that any bounded paratopological group G has countable cellularity (moreover, each cardinal of uncountable cofinality is a precaliber of G). On the other hand, according to [Pr2] for every infinite cardinal τ there is a left bounded left topological group of cellularity τ.

Let G be a bounded semitopological (quasitopological) group. Has G countable cellularity?

Opposition-symmetric lifts and boundary scalarizations of the Thurston metric

P / partially_solved | AIM 研讨会问题汇编

Problem 3.4 (K. Rafi). Is the Thurston metric a degeneration of some better vector-valued symmetric distance on Teichmüller space?

It is introductory text for Problem 3.5, not part of Problem 3.4. It is nevertheless directly relevant notation.

The source list works with the Teichmüller space \(\mathcal T(S)\) of a finite-type surface \(S\) admitting complete finite-area hyperbolic metrics. We assume that \(\mathcal T(S)\) is nontrivial. With \(\mathcal C(S)\) the set of essential simple closed curves and \(\ell_X(\alpha)\) the \(X\)-length of \(\alpha\), the Thurston metric is \[d(X,Y)=d_{\rm Th}(X,Y) =\log\sup_{\alpha\in\mathcal C(S)} \frac{\ell_Y(\alpha)}{\ell_X(\alpha)}. \]

The workshop report supplies useful context for the word “vector-valued”: the talk immediately preceding the problem session was M. Kapovich's “Vector-valued metrics on higher-rank Riemannian symmetric spaces (Cartan projections, conditions for triangular inequality).” In that setting reversal is governed by the opposition involution of a Weyl chamber, rather than by literal equality of oriented vector distances. This report makes that analogy precise and also records what cannot hold under a stricter interpretation.

09503 | AIM-TOPOLOGY-0082

Parabolic flag kernels as braid-stratified projectors

P / partially_solved | AIM 研讨会问题汇编

Are there “braid variety analogues” of projectors?

Its mathematical ambiguity is real, however: neither “projector” nor the category in which it should be idempotent is specified. The official workshop report supplies the missing context. It discusses annular closures of Elias-Hogancamp categorified projectors, used to color link components, and separately records the workshop construction of parabolic braid varieties [AIM]. Thus the intended target appears to be a geometric object attached to braid varieties that plays some role analogous to a Jones-Wenzl/Young/Soergel categorical projector.

This report gives a rigorous partial answer in one precise category. For a standard parabolic subgroup, a proper correspondence assembled from braid relative-position strata has an idempotent structure-sheaf kernel under coherent convolution. It also gives the expected absorption law for nested colors. This does **not** identify that finite kernel with the infinite Soergel complexes used in colored HOMFLYPT homology.

Positivity and split-lift obstructions for categorified colored-Jones recursions

P / partially_solved | AIM 研讨会问题汇编

Lift the recursion relation of the colored Jones Polynomial to categorified CJP.

The record does not specify a knot, a normalization, or which recursion is meant.

There are two mathematically plausible readings.

1. **Color-recursion/AJ reading (used below).** For a fixed knot, the colored Jones sequence is annihilated by a noncommutative polynomial in the color-shift and multiplication operators. Lift such an annihilator to maps, cones, or a filtered acyclic totalization of colored-Jones complexes. 2. **Jones--Wenzl-projector reading.** Lift the recursive construction of the Jones--Wenzl projectors used to define the colored invariant.

The second reading has a substantial known answer: Cooper--Krushkal construct chain complexes categorifying Jones--Wenzl projectors and give an inductive construction modeled on the Frenkel--Khovanov recursion. The first reading remains the sharper unresolved interpretation, and it is the subject of this report.

We fix the reduced normalization, with the colored Jones polynomial of the unknot equal to 1, only to avoid irrelevant units. All statements below apply after fixing any normalization and a particular recurrence presentation.

09529 | AMR-109-0208

Problem 1 - (Geodesics on general flat surfaces).

O / open | AMR 问题清单汇编

(Geodesics on general flat surfaces). Describe the behavior of geodesics on general flat surfaces. Prove (or disprove) the conjecture that the geodesic flow is ergodic on a typical (in 248 15. Problems on billiards, flat surfaces and translation surfaces 249 any reasonable sense) flat surface. Does any (almost any) flat surface have at least one closed geodesic which does not pass through singular points? If the answer is positive then one can ask for the asymptotics for the number of closed geodesics of bounded length as a function of the bound. Note that typically a geodesic representative in a homotopy class of a simple closed curve is realized by a broken line containing many geodesic segments going from one conical singularity to the other. The counting problem for regular closed geodesics (ones which do not pass through singularities) is quite different from the counting problem for geodesics realized by broken lines. The following questions treat billiards in arbitrary polygons in the plane.

Problem 10.2 - (V.

O / open | AMR 问题清单汇编

(V. Turaev) Relate this surgery formula for the Casson-Walker-Lescop invariant with that of Lescop [251]. 32The normalization here is that λ CW(M) = 2 λ C(M) for an integral homology 3-sphere M. 33The normalization here is that λ CWL(M) = (|H1(M; Z)|/ 2) λ CW(M) for a rational homology 3-sphere M. (C. Lescop) In 1984, Casson defined his invariant of integral homology 3- spheres as an integer that “counts” the SU (2)-representations of their funda- mental group in an appropriate way (see [3, 159]). Cappell, L ee and Miller [76] showed that the Casson way of counting SU (2)-representations of the π1 works for any compact Lie group and provides other invariants of in tegral homology spheres.

Problem 11 - [LevelN Torelli Franchetta Problem] What is the second cohomology group of the levelN Torelli group?

P / partially_solved | AMR 问题清单汇编

[LevelN Torelli Franchetta Problem] What is the second cohomology group of the levelN Torelli group? The cell decomposition of ¯M(F) described before is compatible with the ideal cell decompositions of Torelli spaces, i.e., the fatgraph dual to an ideal cell decomposition of F admits a “homology marking” in the sense of [48] as well as admitting the structure of screens. There are thus “DM type” boundaries of each Torelli space replete with an ideal cell decomposition. It is natural to try to understand the topology of these DM-type bordifications of Torelli spaces to approach the following class of problems:

Problem 11.2 - Study the central extension (20) from the point of view of group cohomology as well as geometric topology.

O / open | AMR 问题清单汇编

Study the central extension (20) from the point of view of group cohomology as well as geometric topology. In particular determine the Euler class of this central extension which is an element of the group H 2(Hg,1; Θ 3 Z)∼= Hom(H2(Hg,1), Θ3 Z)⊕ ExtZ(H1(Hg,1), Θ3 Z). This should be an extremely difficult problem. Here we would like to indicate a possible method of attacking it, and in particular a possible way of obtaining additive invariants for the group Θ 3 Z, very briefly. Details will be given in a forthcoming paper. 372 S. Morita Using the traces, we can define a series of certain cohomology classes ˜t2k+1∈H 2(lim←-Aut0(Γ/Γm)) (k = 1, 2,···). These are the “group version” of the elements t2k+1 ∈ H 2(hQ g,1)Sp defined in §6 (Definition 6.1). The homomorphism σ is trivial on Θ 3 Z so that we have the induced homomorphism ˜ σ: Hg,1→ lim←-Aut0(Γ/Γm).

Problem 11.4 - Determine the abelianization of the group Hg,1.

P / partially_solved | AMR 问题清单汇编

Determine the abelianization of the group Hg,1. Is it trivial? Also determine the second homology group H2(Hg,1; Z). Is the rank of it equal to 1 given by the signature? If everything will be as expected, we would obtain non-trivial homomorphisms ˆt2k+1: Θ 3 Z-→Z as secondary invariants associated to the cohomology classes ˜t2k+1. There should be both similarity and difference between these cases and the situation where we interpreted the Casson invariant as the secondary invariant associated to the first Mumford-Morita-Miller class e1 (see [74]). More precisely, they are similar because they are all related to some cohomology classes in H 2(hQ g,1). They are different because e1 is non-trivial in H 2(Hg,1) whereas we expect that the other classes σ∗(˜t2k+1) would be all trivial in the same group. Also recall here that Matumoto [67] and Galewsky and Stern [23] proved that every topological manifold (of dimension n≥ 7) is simplicially triangulable if and only if the homomorphism (21) splits. In view of this result, it should be important to investigate the mod 2 structure of the extension (20) keeping in mind the works of Birman and Craggs [3] as well as Johnson [44] for the case of the mapping class group. However we have come too far and surely many things have to be clarified before we would understand the structure of the group Hg,1. Finally we would like to propose a problem.

Problem 12.1 - Prove that the above characteristic classes induce surjective homomorphism H3(BDiffδ +Σg; Z)-→R2 for any g.

S / solved | AMR 问题清单汇编

Prove that the above characteristic classes induce surjective homomorphism H3(BDiffδ +Σg; Z)-→R2 for any g. The cohomology classes in (22) are stable with respect to g. On the other hand, in [57][58] we found an interesting interaction between the twisted cohomology group of the mapping class group and some well known concepts in symplectic topology such as the flux homomorphism as well as the Calabi homomorphism (see [68] for generalities of the symplectic topology). By making use of this, we defined certain cohomology classes of BSymp δΣg and proved non-triviality of them. In view of the fact that all the known cohomology classes of BDiff δ +Σg as well as BSymp δΣg are stable with respect to the genus, we would like to ask the following problem.

Problem 12.8 - Construct an invariant of KTG’s from configuration space in- tegrals in a natural way.

O / open | AMR 问题清单汇编

Construct an invariant of KTG’s from configuration space in- tegrals in a natural way. Turaev [388] introduced a presentation of 3-manifolds as S1 -bundles over “sha- dow surfaces”, as follows (for details see [388, 40, 384]). A fake surface is a singular surface such that a neighborhood of each point is ho meomorphic to an open subset of the cone over a tetrahedron. A S1 -bundle over a fake surface can appropriately be defined and its isomorphism class is det ermined by the Chern number, which is an integer or half-integer associate d to each face; we call the Chern number the gleam. A shadow surface is a fake surface with gleams associated to the faces. Every (closed) 3-manifold c an be presented by a S1 -bundle over a (closed) shadow surface. The pentagon and hex agon relations (see [388, Figure 1.1 of Chapter VIII]) are moves among shado w surfaces which present a homeomorphic 3-manifold, though they are not enou gh to characterize a homeomorphism class of 3-manifolds. Exercise 12.9 Find a complete set of moves among shadow surfaces which present a homeomorphic 3-manifold. We obtain a shadow surface as a time evolution of a sequence of KTG’s given by KTG operations. Thus, we have relations among links, 3-ma nifolds, KTG’s and shadow surfaces as in the commutative diagram in Figure 2 2; for detailed statements see [40, 384]. Motivated by a complexity of 3-manifolds discussed in [279, 272, 273], D. Thurston introduced the shadow number of 3-manifolds. The shadow num- ber is defined to be the minimal number of vertices of a shadow surf ace. All graph manifolds have shadow number 0 and all surgeries on the Borromean rings have shadow number 1. The volume conjecture might be re lated to the following conjecture. Framed links -exterior Framed link exteriors -surgery Closed 3-manifolds presentation 6 by making S1 -bundle 6 by making S1 -bundle 6 Certain sequences of KTG’s - time evolution Collapsible shadow surfaces - cap off ∂ Closed shadow surfaces Figure 22: Links, 3-manifolds, KTG’s, and shadow surfaces

Problem 13 - (Kernel foliation).

O / open | AMR 问题清单汇编

(Kernel foliation). IsN a complex-analytic (complex-algebraic) orbifold? When is dimCN = dim CO +n-m? On the other hand when does N coincide with the entire connected component of the enveloping stratum H(α′ 1,...,α ′ n)? One of the key properties used in [McM3] for the classification of the closures of orbits of GL(2, R) in each of H(1, 1) and H(2) was the knowledge that on any translation surface of either stratum, one can find a pair of homologous saddle connections. For example, cutting a surface (X,ω) in H(1, 1) along two homologous saddle connections joining distinct zeroes decomposes the surface into two tori, allowing one to apply the machinery of Ratner’s Theorem.

09604 | AMR-109-0221

Problem 14 - (Decomposition of surfaces).

O / open | AMR 问题清单汇编

(Decomposition of surfaces). Given a connected component of the stratum H(α) of Abelian differentials (or of quadratic differentials Q(β) find those configurations of homologous saddle connections (or homologous closed geodesics), which are present on every surface in the stratum. For quadratic differentials the notion of homologous saddle connections (homologous closed geodesics) should be understood in terms of homology with local coefficients, see [MaZo]. The last two problems in this section concern the Teichm¨ uller geodesic flow on the moduli spaces. This is the flow defined by the 1-parameter subgroup (et 0 0 e-t) t∈R onH(α1,...,α m). In any smooth dynamical system the Lyapunov exponents (see [BaPe], [F o2]) are important. Recently, A. Avila and M. Viana [AvVi] have shown the simplicity of the spectrum for the cocycle related to the Teichm¨ uller geodesic flow (strengthening the earlier result of Forni on positivity of the smallest Lyapunov exponent).

09605 | AMR-109-0222

Problem 15 - (Lyapunov exponents).

O / open | AMR 问题清单汇编

(Lyapunov exponents). Study individual Lyapunov exponents of the Teichm¨ uller geodesic flow: - for all known SL(2; R)-invariant subvarieties; - for strata; - for strata of large genera as the genus tends to infinity. Are they related to characteristic numbers of any natural bundles over appropriate compacti- fications of the strata? The motivation for this problem is a beautiful formula of Kontsevich [Ko] representing the sum of the first g Lyapunov exponents in differential-geometric terms. It follows from the Calabi Theorem [Cb] that given a real closed 1-form ω0 with isolated zeroes Σ (satisfying some natural conditions) on a smooth surface S of real dimension two, one 15. Problems on billiards, flat surfaces and translation surfaces 255 can find a complex structure on S and a holomorphic 1-form ω such that the ω0 is the real part of ω. Consider the resulting point (X,ω) in the corresponding stratum. For generic (X,ω) the cocycle related to the Teichm¨ uller geodesic flow acting on H 1(X, R) defines a pair of transverse Lagrangian subspaces H 1(X, R) = L0⊕L1 by means of the Oseledets Theorem ([BaPe]). These subspaces correspond to contracting and to expanding directions. Though the pair (X,ω) is not uniquely determined by ω0, the subspace L0⊂H 1(X, R) does not depend on (X,ω) for a given ω0. Moreover, L0 does not change under small deformations of ω0 that preserve the cohomology class [ω]∈H 1(S, Σ; R). We get a topological object L0 defined in implicit dynamical terms.

Problem 17 - (Converse to dichotomy).

O / open | AMR 问题清单汇编

(Converse to dichotomy). Characterize translation surfaces for which (1) the set of minimal directions coincides with the set of uniquely ergodic directions; (2) the set of completely periodic directions coincides with the set of non-uniquely ergodic directions. 256 P. Hubert, H. Masur, T. Schmidt and A. Zorich Note that Property (2) implies Property (1). In genus g = 2 it is known that for every translation surface which is not a Veech surface there is a direction θ which is minimal and not uniquely ergodic [ChMa]. On the other hand using work of Hubert-Schmidt [HuSt2], B. Weiss has given an example of a surface which is not a Veech surface and yet for which Property (2) holds. (This surface is obtained as a ramified covering over a Veech surface with a single ramification point.) As mentioned above, a closed orbit avoiding the conical singularities of the flat surface deter- mines a cylinder of parallel lines, all of the same length. It is of interest to find the asymptotics for the number of cylinders (in all possible directions) of lengths less than a given number. In the case of the standard flat torus the number of cylinders of length at most L is asymptotic to 1 ζ(2)πL2. Each Veech surface also has quadratic asymptotics [V e3] and the same is true for generic surfaces in each stratum [EsMa].

Problem 19 - (Error term for counting functions).

P / partially_solved | AMR 问题清单汇编

(Error term for counting functions). What can be said about the error term in the quadratic asymptotics for counting functions N ((X,ω),L)∼c·L2 on a generic translation surface (X,ω)? In particular, is it true that lim sup L→∞ log|N (S,L)-c·L2| logL < 2? Is the lim sup the same for almost all flat surfaces in a given connected component of a stratum? The classical Circle Problem gives an estimate for the error term in the case of the torus. Veech proved that for Veech surfaces the limsup in the error term is actually a limit, see [V e3]. However, nothing is known about the value of this limit. One may ask whether there is a uniform bound for this limit for Veech surfaces in a given stratum or even for the square-tiled surfaces in a given stratum.

Problem 1: - Determine the metric completion of the Gromov boundary of C(S) and relate this metric completion to the geometry of C…

P / partially_solved | AMR 问题清单汇编

Determine the metric completion of the Gromov boundary of C(S) and relate this metric completion to the geometry of C(S). There is yet another way to construct unparametrized uniform quasi-geodesics in C(S). Namely, Teichm¨ uller spaceforS is the space Tg,m of marked isometry classes of complete hyperbolic met- rics on S of finite volume. The Teichm¨ uller space can naturally be identified with a domain in C3g-3+m (see Chapter 6 of [IT]). By a classical result of Bers (see [Bu]), there is a number χ> 0 such that for every complete hyperbolic metric h on S there is a pants decomposition for S consisting of simple closed h- geodesics of length at most χ. Moreover, the diameter in C(S) of the set of simple closed curves on S of h-length at most χ is bounded from above by a universal constant D >0. Thus we can define a map Ψ: Tg,m→C (S) by associating to a marked hyperbolic metric h a simple closed curve of h-length at most χ. For any two such maps Ψ, Ψ′ we then have sup h∈Tg,md(Ψ(h), Ψ′(h))≤D. The Teichm¨ uller metriconTg,m is a complete Finsler metric which is just the Kobayashi metric on the domain in C3g-3+m representingTg,m (see [IT]). Through any two distinct points in Tg,m passes a unique Teichm¨ uller geodesic. Each such geodesic line in Tg,m is uniquely determined by its endpoints in the Thurston boundary ofTg,m which is just the space PML of projective measured laminations on S. The supports of the two measured laminations on S defining the endpoints of the geodesic together fill up the surface S, i.e. every simple closed curve on S intersects at least one of the two laminations transversely. These laminations then define a holomorphic quadratic 14. Geometric properties of the mapping class group 235 differential (we refer to Section 4 of [Ke] for a discussion of this fact). The following result is implicitly contained in the paper [MM1] by Masur and Minsky; an explicit proof using a result of Rafi [R] can be found in Section 4 of [H4].

Problem 2 - (Billiards in general polygons).

O / open | AMR 问题清单汇编

(Billiards in general polygons). Does every billiard table have at least one regular periodic trajectory? If the answer is affirmative, does this trajectory persist under deformations of the billiard table? If a periodic trajectory exists, find the asymptotics for the number of periodic trajectories of bounded length as a function of the bound. Describe the behavior of a generic regular billiard trajectory in a generic polygon; in particular, prove (or disprove) the assertion that the billiard flow is ergodic. 1 We note that the case of triangles is already highly non-trivial. For recent work on billiards in obtuse triangles see [Sc1] and [Sc2]. In the case of triangles the notion of generic can be interpreted as follows. The space of triangles up to similarity can be parametrized as the set of triples (θ1,θ 2,θ 3) with ∑θi =π and eachθi> 0. It is naturally an open simplex. Generic then refers to the natural Lebesgue measure. To motivate the next problem we note that there is a close connection between the study of interval exchange transformations and billiards in rational polygons (defined below). An important technique in the study of interval exchange maps is that of renormalization. Given an interval exchange on the unit interval one can take the induced transformation on a subinterval. The resulting map is again an interval exchange map, and if one renormalizes so that the new interval has length one, then this gives a transformation on the space of unit interval exchange maps. This transformation is called the Rauzy-Veech induction ([Ra], [V e2]), and it has proved to be of fundamental importance. There is a corresponding notion for the renormalization of translation surfaces given by the Teichm¨ uller geodesic flow.

Problem 2.11 - Hempel’s distance function was chosen so that it would capture the geometry, and indeed it does that very well, yet i…

S / solved | AMR 问题清单汇编

Hempel’s distance function was chosen so that it would capture the geometry, and indeed it does that very well, yet in some ways it feels unnatural. The Hatcher-Thurston complex HT(S) seems much more natural to us, since and pairs of vertices in the latter determine a Heegaard diagram, and one gets every genus g Heegaard diagram this way. One wonders whether it is possible to redefine Heegaard distance, using HT(S), or perhaps even P(S) or one of the other complexes that has proved to be so useful in studying subgroups of M, and whether new things will be learned that way? We have focussed our discussion, up to now, on the 3-manifold that is determined by a choice of an element φ in the group M via the Heegaard splitting construction. A very different construction which also starts with the choice of an element in the mapping class group, say α∈M g, produces the mapping torus of α, i.e. the surface bundle (S× [0, 1])/α, defined by setting (p, 0) = (α(p), 1). Surface bundle structures on 3-manifolds, when they exist, are also not unique. Two surface bundles (S×I)/α, (S×I)/α′ are equivalent if and only if α,α ′ are in the same conjugacy class inMg. In [1] an interesting description is given of a natural way to produce, for each (S×I)/α, a related Heegaard splitting HυβH ′. Choose a fiber S of (S×I)/α, say S×{ 0} and choose points p,q∈S, p̸=q, p̸=α(q). Let P andQ be disjoint closures of regular neighborhoods of p×[0, 1/2] and q× [1/2, 1] respectively. Set H = (S× ([0, 1/2]-Q)∪P, H ′ = (S× [1/2, 1]-P)∪Q. 152 J. Birman Note that H and H ′ are homeomorphic handlebodies of genus 2 g + 1 which are embedded in (S×I)/α and identified along their boundaries, so they give a Heegaard decomposition of (S×I)/α. We call it the bundle-related Heegaard splitting of (S×I)/α. It is HυβH ′ for some β∈M 2g+1. We have several problems that relate to this construction:

09627 | AMR-109-0116

Problem 2.11 - Let g≥ 3 and b≥ 1.

S / solved | AMR 问题清单汇编

Let g≥ 3 and b≥ 1. Let a1,a 2,... be an infinite sequence of nonseparating simple closed curves on an oriented surface S of genus g with b boundary components. In the mapping class group Modb g of S, does the limit lim n→∞ c(ta1ta2··· tan) n exist? If it does, is it always positive? More generally, is there a positive number K such that c(ta1ta2··· tan)≥nK for all n? Suppose that there is a constant K such that c(ta1ta2··· tan) ≥ nK for any sequence of nonseparating simple closed curves a1,a 2,... and for all n. If f ∈ Modb g can be written as a product of right Dehn twists and if f = ta1ta2··· tak, then c(f) = c(ta1ta2··· tak)≥ kK. Hence, k≤ c(f)/K. Therefore, a positive answer to Problem 2.11, with K independent of sequences, implies a positive answer to Problem 2.9. We would like to note that the hypothesis b≥ 1 in Problem 2.11 is necessary. Otherwise, the identity element in Mod g can be written as a product of right Dehn twists, say 1 = ta1ta2··· tan. Then for the sequence a1,a 2,...,a n,a 1,a 2,...,a n,a 1,a 2,...,a n,... the limit in Problem 2.11 is zero. We would also like to note that when b≥ 1, the identity in Mod b g cannot be expressed as a product of right Dehn twists. By embedding the surface with boundary into a closed surface of bigger genus, the proof of this follows from a theorem of Smith [41]; on a closed surface S, if 1 = ta1ta2··· tan, then the curves a1,a 2,...,a n fill up S. (I first learned this fact from Rostislav Matveyev in June 2000.)

Problem 2.12 - Forg≥ 2, determine the irreducible factors of the graded pieces of the Malcev Lie algebra tg ofIg as Sp-modules.

O / open | AMR 问题清单汇编

Forg≥ 2, determine the irreducible factors of the graded pieces of the Malcev Lie algebra tg ofIg as Sp-modules. While Hain gives in [Ha3] an explicit and reasonably simple presentation for tg when g >6, Problem 2.12 still seems to be an involved problem in classical representation theory. As Chris Leininger pointed out to me, all of the questions above have natural “virtual versions”. For example, one can ask about the classification of normal subgroups of finite index subgroups of Mod g. Another variation is the classification of virtually normal subgroups of Mod g, that is, subgroups whose normalizers in Mod g have finite index in Mod g.

Problem 2.12 - Let r be a positive integer and let Γr be the (normal) subgroup of Modg generated by the rth powers of all Dehn twists.

P / partially_solved | AMR 问题清单汇编

Let r be a positive integer and let Γr be the (normal) subgroup of Modg generated by the rth powers of all Dehn twists. Is Γr of infinite index? If we let Nr to be the normal closure in the mapping class group Mod g of the rth power of a single Dehn twist about a nonseparating simple closed curve, then by a result of Humphries [17] the index of Nr is finite in Mod g for all g when r = 2 and for (g,r) = (2, 3). Thus, the answer to Problem 2.12 is no in these cases. It is also known from [17] and [10] that Nr is of infinite index if r= 2, 3, 4, 6, 8, 12. Clearly, Nr is contained in Γ r. Let PMod b g,p denote the subgroup of Mod b g,p consisting of the isotopy classes of those diffeo- morphisms which fix each puncture. If g≥ 4, then the homology group H2(PModb g,p; Z) is iso- morphic to Zp+1. (cf. [13], [39] and [33].) (We note that the roles of the subscript p and the superscript b are interchanged in [33].) 5. 09635 | AMR-109-0171

Problem 2.14 - A 3-manifold is fibered if it admits a surface bundle structure.

S / solved | AMR 问题清单汇编

A 3-manifold is fibered if it admits a surface bundle structure. It is virtually fibered if it has a finite-sheeted cover that admits a surface bundle structure. In [49] Thurston asked whether every finite-volume hyperbolic 3-manifold is virtually fibered. This question has turned out to be one of the outstanding open problems of the post-Thurston period in 3-manifold topology. We ask a vague question: does the distance and the very special nature of the Heegaard splitting that's associated to a 3-manifold which has a surface bundle structure give any hint about the possibility of a 3-manifold which is not fibered being virtually fibered? With regard to Problem 2.14, we remark that the first examples of hyperbolic knots which are virtually fibered but not fibered were discovered 20 years after the question was posed, by Leininger [28] even though it seems to us that fibered knots should have been one of the easiest cases to understand. As we write this, in February 2005, there seems to be lots to learn about virtually fibered 3-manifolds.

Problem 2.15 - (Frequency of low symmetry).

O / open | AMR 问题清单汇编

(Frequency of low symmetry). Let H denote the set of integers g≥ 2 such that N (g) = 8(g + 1). Find the s0 for which the series ∑ g∈Hg-s converges absolutely for the real part$\Re$(s) of s satisfying$\Re$(s)>s 0, and has a singularity at s =s0. There are various refinements and variations on Problem 2.15. For example, Accola proves in [Ac] that when g is divisible by 3, then N (g)≥ 8(g + 3), with the bound attained infinitely often. One can try to build on this for other g, and can also ask for the frequency of this occurence. One can begin to refine Hurwitz's Theorem by asking for bounds of orders of groups of auto- morphisms which in addition satisfy various algebraic constraints, such as being nilpotent, being solvable, being a p-group, etc. There already exist a number of theorems of this sort. For example, Zomorrodian [Zo] proved that if Aut(Xg) is nilpotent then it has order at most 16(g- 1), and if this bound is attained then g- 1 must be a power of 2. One can also ask for lower bounds in this context. As these kinds of bounds are typically attained and not attained for infinitely many g, one then wants to solve the following.

Problem 2.16 - (Automorphism groups with special properties).

O / open | AMR 问题清单汇编

(Automorphism groups with special properties). LetP be a property of finite groups, for example being nilpotent, solvable, or a p-group. Prove a version of Larsen ’s theorem which counts those g for which the upper bound of | Aut(Xg)| is realized for some Xg withAut(Xg) havingP. Similarly for lower bounds. Determine the least g for which each given bound is realized. Many of the surfaces realizing the extremal bounds in all of the above questions are arithmetic, that is they are quotients of H2 by an arithmetic lattice. Such lattices are well-known to have special properties, in particular they have a lot of symmetry. On the other hand arithmetic surfaces are not typical. Thus to understand the “typical” surface with symmetry, the natural problem is the following.

Problem 2.19 - (Canonical basepoints for Mg).

O / open | AMR 问题清单汇编

(Canonical basepoints for Mg). Find other properties of automorphisms or automorphism groups that determine a unique point of Mg. For example, is there a unique Riemann surface of genus g≥ 2 whose automorphism group is nilpotent, and is the largest possible order among nilpotent automorphism groups of genus g surfaces? A Hurwitz surface is a hyperbolic surface attaining the bound 84(g- 1). As the quotient of such a surface by its automorphism group is the (2, 3, 7) orbifold, which has a unique hyperbolic metric, it follows that for each g≥ 2 there are finitely many Hurwitz surfaces. As these are the surfaces of maximal symmetry, it is natural to ask precisely how many there are.

Problem 2.2 - Compute CommModg (Γ) for various subgroups Γ< Modg.

O / open | AMR 问题清单汇编

Compute CommModg (Γ) for various subgroups Γ< Modg. Paris-Rolfsen and Paris (see, e.g., [Pa]) have proven that most subgroups of Mod g stabiliz- ing a simple closed curve, or coming from the mapping class group of a subsurface of S, are self-commensurating in Mod g. Self-commensurating subgroups, that is subgroups Γ < H with CommH (Γ) = Γ, are particularly important since the finite-dimensional unitary dual of Γ in- jects into the unitary dual of H; in other words, any unitary representation of H induced from a finite-dimensional irreducible unitary representation of Γ must itself be irreducible. V olumes of representations. Consider the general problem of classifying, for a fixed finitely generated group Γ, the set Xg(Γ):= Hom(Γ, Modg)/ Modg of conjugacy classes of representations ρ: Γ → Modg. Here the representations ρ1 and ρ2 are conjugate if ρ1 =Ch◦ρ2, where Ch: Mod g→ Modg is conjugation by some h∈ Modg. Suppose Γ = π1X whereX is, say, a smooth, closed n-manifold. Since Mg is a classifying space for Mod g, we know that for each for each [ρ]∈X g(Γ) there exists a smooth map f:X→M g with f∗ =ρ, and that f is unique up to homotopy. Eachn-dimensional real cocycle ξ onMg then gives a well-defined invariant νξ:Xg(Γ)→ R defined by νξ([ρ]):= ∫ X f ∗ξ It is clear that νξ([ρ]) does not depend on the choices, and indeed depends only on the cohomology class of ξ. As a case of special interest, let X be a 2 k-dimensional manifold and let ωWP denote the Weil-Petersson symplectic form on Mg. Define the complexk-volume of ρ:π1X→ Modg to be Volk([ρ]):= ∫ X f ∗ωk WP

Problem 2.2 - Decompose the representation on H0 into irreducible representations of ModΣ.

O / open | AMR 问题清单汇编

Decompose the representation on H0 into irreducible representations of ModΣ. When G = U(1), and Σ is the 2-torus, Hom(π,G)/G naturally identifies with T 2, by the functions α,β corresponding to a basis of π1(Σ). The functions φm,n:=αmβn, forms a Hilbert basis of H, indexed by (m,n)∈ Z2. The ModΣ-representation on H arises from the linear GL(2, Z)-action on its basis Z2. The GL(2, Z)-orbits on Z2 are indexed by integers d≥ 0. The orbit of (d, 0) consists of all (m,n)∈ Z2 with gcd(m,n) = d. These are Hilbert bases for irreducible constituents Cd of H. The irreducible constituents Cd admit an alternate description, as follows. The d-fold covering homomorphism G Φd - - →G induces a covering space Hom(π,G)/G-→ Hom(π,G)/G. Let Ld denote the closure of the image of the induced map H-→ H. Then Ld = ˆ⊕ d′|d Cd′ so Cd consists of the orthocomplement in Ld of the sum of all Ld′ for d′|d but d′=d.

Problem 2.2 - Is there an endomorphism of the mapping class group of a (closed) orientable surface onto an infinite index infinite…

S / solved | AMR 问题清单汇编

Is there an endomorphism of the mapping class group of a (closed) orientable surface onto an infinite index infinite subgroup? If there is one such endomorphism f, is it true that f restricted to the image of fn is injective for some n? We conjecture that there is no such f. There are also results on injective homomorphisms from subgroups of finite index into the extended mapping class group Mod ∗ g,p, the group of isotopy classes of all (including orientation- reversing) diffeomorphisms of the surface S of genus g with p punctures. Let Γ be a subgroup of finite index in Mod ∗ g,p. Any injective homomorphism from Γ into Mod ∗ g,p is the restriction of an automorphism of Mod ∗ g,p. This result was proved by Irmak [18, 19] for g = 2, p≥ 2 and for g≥ 3, and by Bell and Margalit [1] for g = 0. One more result about the homomorphisms from the mapping class group we mention is the following.

Problem 2.3 - (Volume spectrum).

O / open | AMR 问题清单汇编

(Volume spectrum). Determine for each 1≤ k≤ 3g- 3 the image of Volk: Xg(Γ)→ R. Determine the union of all such images as Γ ranges over all finitely presented groups. It would also be interesting to pose the same problem for representations with special geometric constraints, for example those with holomorphic or totally geodesic (with respect to a fixed metric) representatives. In particular, how do such geometric properties constrain the set of possible volumes? Note that Mirzakhani [Mir] has given recursive formulas for the Weil-Petersson volumes of moduli spaces for surfaces with nonempty totally geodesic boundary. Invariants from linear representations. Each linear representation ψ: Mod g→ GLm(C) provides us with many invariants for elements of Xg(Γ), simply by composition with ψ followed by taking any fixed class function on GL m(C). One can obtain commensurability invariants for subgroups of Mod g this way as well. While no faithful ψ is known for g ≥ 3 (indeed the existence of such a ψ remains a major open problem), there are many such ψ which give a great 2. Some problems on mapping class groups and moduli space 17 deal of information. Some computations using this idea can be found in [Su2]. I think further computations would be worthwhile.

Problem 2.3 - Work out the details of this construction of the completion Yg of Yg.

O / open | AMR 问题清单汇编

Work out the details of this construction of the completion Yg of Yg. Show that L:Yg→ [0,∞) extends to L:Yg→ [0,∞) and is a proper map. Ideally, inclusion Yg→Yg should be a homotopy equivalence (and Yg-Yg should be the boundary of the manifold with corners Yg). Study L as a “Morse” function. Critical points of L are most likely not isolated; however, explain the change in the homotopy type of L -1 [0,t] as t passes through a critical value. For example, take the case g = 2. Spaces added at infinity are Y 1 1×Y 1 1×S1 = H2× H2×S1 and the restriction of L to such a set factors through H2× H2 where it has a unique minimum and no other critical points. Thus this set contains a “mincircle”. Hope. A point of Y 2 is a local minimum of L iff it belongs to one of these mincircles. In addition there are isolated critical points of index 1 that connect up these circles in a tree-like pattern. Thus Y 2 and Y2 are homotopy equivalent to a wedge of circles, one circle for every splitting, recovering the theorem of Mess mentioned above. 2the smallest dimension of a space homotopy equivalent to Yg 1. 09664 | AMR-109-0012

Problem 2.6 - (Holomorphic representatives).

O / open | AMR 问题清单汇编

(Holomorphic representatives). Find an algorithm or a group-theoretic invariant which determines or detects whether or not a given representation ρ: π1Σh → Modg has a holomorphic representative. 2. Some problems on mapping class groups and moduli space 19 Note that a necessary, but not sufficient, condition for a representation ρ:π1Σh→ Modg to be holomorphic is that it be irreducible, i.e. there is no essential isotopy class of simple closed curve α in Σ g such that ρ(π1Σh)(α) = α. I believe it is not difficult to give an algorithm to determine whether or not any given ρ is irreducible or not. We would like to construct and classify (up to conjugacy) such ρ. We would also like to compute their associated invariants, such as ν(ρ):= ∫ Σh f ∗ωWP whereωWP is the Weil-Petersson 2-form on Mg, and where f: Σ h→M g is any map with f∗ =ρ. This would give information on the signatures of surface bundles over surfaces, and also on the Gromov co-norm of [ωWP]∈H ∗(Mg, R). The classification question is basically impossible as stated, since e.g. surface groups surject onto free groups, so it is natural to first restrict to injective ρ. Using a technique of Crisp-Wiest, J. Crisp and I show in [CF] that irreducible, injective ρ are quite common.

09666 | AMR-109-0111

Problem 2.6 - Let Γ be a finite index subgroup of Modg.

P / partially_solved | AMR 问题清单汇编

Let Γ be a finite index subgroup of Modg. Is it true that H 1(Γ; Z) = 0? There are some partial answers to Problem 2.6. If g≥ 3 and if Γ contains the Torelli group, it was proved by McCarthy [37] that H 1(Γ; Z) = 0. However, if g = 2, this is not true anymore; the first examples of finite index subgroups in Mod 2 with nontrivial first cohomology were constructed by McCarthy in [37] and by Taherkhani in [43]. Moreover, if g = 1 or 2, it was shown in [31] that for each positive integer n≥ 2 the mapping class group Mod g contains a subgroup Γ n of finite index which admits a homomorphism onto a free group of rank n. In particular, the rank of H 1(Γn; Z) is at least n. We note that a positive answer to Problem 1 (a) implies a positive answer to Problem 2.6. Note also that since there is a subgroup of finite index in Mod 2 mapping onto a finite index subgroup of Mod 1, the hypothesis g≥ 3 in Problem 1 is necessary. A special case of Problem 2.6 is still interesting. Suppose that g≥ 3 and that Γ is s subgroup of finite index in Mod g containing the Johnson group (or Johnson kernel) Kg, the subgroup of Modg generated of by Dehn twists about separating simple closed curves. Is it true that any homomorphism Γ → Z is trivial? 1After this paper is written up, Behrstock and Margalit announced in [] that there exists an isomorphism between finite index subgroups of Mod ∗ 1,2 which is not the restriction of an inner automorphism. 88 M. Korkmaz

Problem 3 - Give a useful (piecewise) tropical description of the two elementary transformations.

O / open | AMR 问题清单汇编

Give a useful (piecewise) tropical description of the two elementary transformations. One thus immediately derives a (piecewise) tropical polynomial representation of the mapping class groups. What properties does it have, for instance under iteration? As alternative coordinates, [9] describes a family of curves whose intersection numbers alone coordinatize measured foliations of compact support (but there are relations), and presumably these intersection numbers could be computed using Theorem 3. We also wonder what are further applications or consequences of all these formulas.

Problem 3 - Given a topological description of fk0,fk1 describe fk0+k1.

O / open | AMR 问题清单汇编

Given a topological description of fk0,fk1 describe fk0+k1. A good understanding of this would enable one to drop the rather artificial introduction of the subclass D(0) g,ν,p in the discussion above. More generally still, if we have two pencils on a symplectic manifold X with fibre classes F1,F 2 one can ask for a description of a TLP with fibre F1 +F2 (if such exists). This might 11. Lefschetz pencils and mapping class groups 171 give information about the problem of describing the classes represented by symplectic forms on a fixed 4-manifold. Rather than trying to use the TLP description to reduce questions to combinatorics one can attempt to use it as a tool to prove general properties of symplectic 4-manifolds. So far, this has been more fruitful, giving a new approach to Taubes' results independent of the Seiberg-Witten theory [6], [13], [9]. There is also a generalisation of the TLP description to other 4-manifolds [3] and there are many things one could try here; for example to prove that any 4-manifold has "simple type". One thing that should be important to understand is the role of the canonical class K(ω). Using the Seiberg-Witten theory and pseudo-holomorphic curve techniques, a complete classification is known of symplectic 4-manifolds with ω.K (ω)< 0, i.e. withθ< 0 in our notation above. The only examples are the standard ones given by rational and ruled complex surfaces [8]. It would be interesting to derive this by the Lefschtez pencil method:

O / open | AMR 问题清单汇编

Give a homotopy theoretic construction of a map ρh: Ω ∞CP ∞ -1→K Sp(Z) with ρ≃ ρh◦α, at least after localization at a regular prime. (The 2-local case is of particular interest; cf. [12]). The rational cohomology of Ω ∞CP ∞ -1 is easy to list. For each connected component, H ∗(Ω∞ k CP ∞ -1; Q) = Q[κ′ 1,κ ′ 2,...] 6. The mapping class groups and homotopy theory 97 whereκi =α∗(κ′ i) are the standard Miller-Morita-Mumford classes of degree 2 i, see [5], [15], [17] for further details. The rational cohomology of B Sp(Z) was calculated by Borel: H ∗(B Sp(Z); Q)∼=H ∗(Sp/U; Q)∼= Q[c1,c 3,...]. where c2i+1 is the image of the (2 i + 1)st Chern class under the natural map from Sp /U to BU. Moreover,ρ∗(c2i+1) is a non-zero multiple of κ′ 2i+1 so that κ2i+1 restricts to zero in the rational cohomology of the Torelli group, [17].

P / partially_solved | AMR 问题清单汇编

Prove (or disprove) that the even Mumford-Morita-Miller classes e2i∈H 4i(Ig; Q) are non-trivial, in a suitable stable range, as cohomology classes of the Torelli group. The difficulty of the above problem comes from the now classical fact, proved by Johnson [40], that the abelianization of the Torelli group is very big, namely H1(Ig; Q)∼=UQ (g≥ 3). Observe that if Ig were perfect, then the above problem would have been easily solved by simply applying the Quillen plus construction to each group of the group extension (1) and then looking at the homotopy exact sequence of the resulting fibration. The work of Igusa [38] (in particular Corollary 8.5.17) shows a close connection between the above problem with another very important problem (see Problem 4.4 in § 4) of non-triviality of Igusa’s higher Franz-Reidemeister torsion classes in H 4i(IOutn; R) (Igusa uses the notation Out hFn for the group IOut n). We also refer to a recent work of Sakasai [95] which is related to the above problem. 22. Cohomological structure of the mapping class group and beyond 355 Next we recall the following two well-known problems about the structure of the Torelli group which are related to a foundational work of Hain [29].

Problem 3.1 - Study, systematically and with the help of computers, the finite quotients of Mg which do not factor through Sp (2g, Z).

P / partially_solved | AMR 问题清单汇编

Study, systematically and with the help of computers, the finite quotients of Mg which do not factor through Sp (2g, Z). We remark that Problem 3.1 would simply have been impossible in the days before high-speed computers, but it is within reach now. A fairly simple set of defining relations for Mg,0,0 can be found in [52]. As for checking whether any homomophism so-obtained factors through Sp(2 g, Z), there is are two additional relations to check, namely the Dehn twist on a genus 1 separating curve for g≥ 2, and the Dehn twist on a genus 1 bounding pair (see [23]) for g≥ 3. One method of organization is to systematically study homomorphisms of Mg (maybe starting with g = 3) into the symmetric group Σ n, beginning with low values of n and gradually increasing n. One must check all possible images of the generators of Mg in Σ n, asking (for each choice) whether the defining relations in Mg and Sp(2 g, Z) are satisfied. Note that if one uses Dehn twists on non-separating curves as generators, then they must all be conjugate, which places a big restriction. There are additional restrictions that arise from the orders of various generating sets, for example in [7] it is proved that Mg is generated by 6 involutions. Of course, as one proceeds with such an investigation, tools will present themselves and the calculation will organize itself, willy-nilly. We do not mean to suggest that non-finite quotients are without interest, so for completeness we pose a related problem:

Problem 3.1 - What is the smallest n = n(g) such that MCG (Sg) admits a properly dis- continuous action on Rn?

P / partially_solved | AMR 问题清单汇编

What is the smallest n = n(g) such that MCG (Sg) admits a properly dis- continuous action on Rn? on a contractible n-manifold? (The answers are expected to be the same.) Of course, MCG (Sg) acts properly discontinuously on Teichm¨ uller space Tg~= R6g-6 so it is a natural guess that n(g) = 6 g- 6 (for g≥ 2; clearly n(1) = 2). The question is motivated by the work in [BKK02] where a technique is developed for finding lower bounds on the dimension n(Γ) of a contractible manifold where a given group Γ acts properly discontinuously. The optimal n(Γ) is called the action dimension of Γ. For example, n(Fg 2) = 2 g and if Γ is a lattice in a connected semisimple Lie group G then n(Γ) = dim G/K (where K is a maximal compact subgroup) [BF02a]. As observed in [BKK02], if Bk is the braid group on k strands then n(Bk) = 2 k- 3 (k≥ 2) which equals the dimension of the corresponding Teichm¨ uller space. The method is this. Find a convenient finite simplicial complex L that does not embed in Rm “for homological reasons”. Such a complex is called an m-obstructor complex. Complexes used in all applications are joins of pointed spheres (a pointed sphere Sk + is a sphere Sk union a disjoint point). E.g. the “utilities graph” is the join of two pointed 0-spheres, it does not embed in the plane for homological reasons, and is a 2-obstructor complex. For example, if L =Sk1 + ∗Sk2 + ∗···∗ Skp + then L is an m-obstructor complex 3 for m =k1 +k2 +··· +kp + 2p- 2 and all obstructor complexes used in [BKK02] and [BF02b] have this form. Then one wants to find a map F:L× [0,∞)→X which is proper and expanding and X is a proper metric space on which the given group Γ acts isometrically, properly discontinuously and cocompactly. The map F is expanding if for any two disjoint simplices σ,τ ⊂L we have lim t→∞ d(F (σ× [t,∞)),F (τ× [t,∞))) = ∞ For the case Γ = MCG (Sg) it is natural to take X to be the subset T ≥ϵ g of Teichm¨ uller space consisting of marked surfaces with no closed geodesics of length < ϵ for a certain small ϵ > 0. When such a map is found it then follows from [BKK02] that n(Γ)≥m + 2.

Problem 3.10 - Find a finitely presented subgroup H < Modg for which there are infinitely many conjugacy classes of finite subgroups…

S / solved | AMR 问题清单汇编

Find a finitely presented subgroup H < Modg for which there are infinitely many conjugacy classes of finite subgroups in H. The motivation for this problem comes from a corresponding example, due to Bridson [Br], of such an H in GL(n, Z). One might to solve Problem 3.10 by extending Bridson’s construction to Sp(2 g, Z), pulling back such an H, and also noting that the natural map Mod g→ Sp(2g, Z) is injective on torsion. Another determination of the variety of subgroups of Mod g is the following. Recall that the isomorphism problem for a collection S of finitely presented groups asks for an algorithm which takes as input two presentations for two elements of S and as output tells whether or not those groups are isomorphic.

Problem 3.17 - (Logarithmic densities of the Johnson filtration).

O / open | AMR 问题清单汇编

(Logarithmic densities of the Johnson filtration). Determine the asymptotics of dlog(Ig(m)) both as g→∞ and as m→∞. Indeed, as far as I know, even the asymptotics of the (logarithmic) density of the kth term of the lower central series of π1Σg in π1Σg as k→∞ has not been determined. Entropy. The exponential growth rate of a group Γ with respect to a finite generating set S is defined as w(Γ,S):= lim r→∞ (Br(Γ,S))1/r 4For a wonderful discussion of this kind of issue, see Barry Mazur’s article [Maz]. 30 B. Farb where Br(Γ,S) denotes the cardinality of the r-ball in the Cayley graph of Γ with respect to the generating set S; the limit exists since β is submultiplicative. The entropy of Γ is defined to be ent(Γ) = inf {logw(Γ,S): S is finite and generates Γ } Among other things, the group-theoretic entropy of ent(π1M) of a closed, Riemannian mani- fold M gives a lower bound for (the product of diameter times) both the volume growth entropy of M and the topological entropy of the geodesic flow on M. See [Harp1] for a survey. Eskin-Mozes-Oh [EMO] proved that nonsolvable, finitely-generated linear groups Γ have positive entropy. Since it is classical that the action of Mod g on H1(Σg, Z) gives a surjection Modg→ Sp(2g, Z), it follows immediately that ent(Mod g)> 0. This method of proving positivity of entropy fails for the Torelli group Ig since it is in the kernel of the standard symplectic repre- sentation of Mod g. However, one can consider the action of Ig on the homology of the universal abelian cover of Σ g, considered as a (finitely generated) module over the corresponding covering group, to find a linear representation of Ig which is not virtually solvable. This is basically the Magnus representation. Again by Eskin-Mozes-Oh we conclude that ent(Ig)> 0.

The level set R3∩κ-1(2) consists of characters of abelian representations, and ModΣ is ergodic on each of the four connected components of the smooth part of R3∩κ-1(2). When 2 <t ≤ 18, the ModΣ-action on R3∩κ-1(t) is ergodic. Fort> 18, the level sets R3∩κ-1(t) display both proper dynamics and chaotic dynamics. The region (-∞,-2]3 consists of characters of discrete embeddings ρ where the quotient hyperbolic surface H2/ρ(π) is homeomorphic to a three-holed sphere. Every homotopy equivalence Σ -→ P, where P is a hyperbolic surface homeomorphic to a three-holed sphere, determines such a character. Furthermore these determine closed triangular regions which are freely permuted by ModΣ. On the complement of these wandering domains the action is ergodic. WhenG = PGL(2, R), the group of (possibly orientation-reversing) isometries of H2, a similar analysis was begun by Stantchev [94, 52]. One obtains similar dynamical systems, where ModΣ acts now on the space of representations into the group G± = SL(2, C)∩ (GL(2, R)∪ i GL(2, R)) 13. Mapping class group dynamics on surface group representations 215 which doubly covers the two-component group PGL(2, R). These G±-representations are again parametrized by traces. They comprise four components, one of which is the subset of R3 parametrizing SL(2, R)-representations discussed above. The other three components are R×iR×iR, i R× R×iR, i R×iR× R respectively. Consider iR× R×iR. For -14≤t< 2, the ModΣ-action is ergodic, but when t< -14, wandering domains appear. The wandering domains correspond to homotopy-equivalences Σ-→P, where P is a hyperbolic surface homeomorphic to a two-holed projective plane. The action is ergodic on the complement of the wandering domains.

Problem 3.23 - (T.

P / partially_solved | AMR 问题清单汇编

(T. Kohno) Construct explicitly a universal invariant of finite type for links in Σ × [0, 1] with values in AΣ. In the case of genus 0 the above problem is solved by Kontsevic h integral. In higher genus case a suggestion for a construction of a univer sal invariant was given by Deligne at Oberwolfach meeting 1995. In the case of a punctured surface the problem was solved by Andersen, Mattes and Reshe tikhin. Let G be a simple Lie group and MG(Σ) the moduli space of G flat connections on Σ. The space of smooth functions on MG(Σ) denoted by C(MG(Σ)) has a structure of a Poisson algebra coming from a symplectic stru cture on MG(Σ). The algebraAΣ has also a Poisson algebra structure (see [8]). If each compo nent ofAΣ is colored by a representation of G, then there is a natural Poisson algebra homomorphism τ:AΣ → C(MG(Σ)). Problem 3.23 is related to the following problem.

Problem 3.3 - (Fast conjugacy problem).

O / open | AMR 问题清单汇编

(Fast conjugacy problem). Find a polynomial time algorithm to solve the con- jugacy problem in Modg. Is there a quadratic time algorithm, as for the word problem? As explained in the example on page 11, a solution to Problem 3.3 would be a major step in finding a polynomial time algorithm to solve the homeomorphism problem for 3-manifolds that fiber over the circle. Almost convexity. In [Ca] Cannon initiated the beautiful theory of almost convex groups. A group Γ with generating set S is almost convex if there exists C >0 so that for each r >0, and for any two points x,y ∈ Γ on the sphere of radius r in Γ with d(x,y) = 2, there exists a path γ of length at most C connectingx toy and lying completely inside the ball of radius r in Γ. There is an obvious generalization of this concept from groups to spaces. One strong consequence of the almost convexity of Γ is that for such groups one can recursively build the Cayley graph of Γ near any point x in the n-sphere of Γ by only doing a local computation involving elements of Γ lying (universally) close to x; see [Ca]. In particular one can build each n-ball, n≥ 0, and so solve the word problem in an efficient way. 3The second ingredient, crucial but ignored by some authors, is the computability of the Thurston norm. 2. Some problems on mapping class groups and moduli space 25

Problem 3.3 - Let ug denote the graded Lie algebra associated to the prounipotent radical of the relative Malcev completion of Ig d…

O / open | AMR 问题清单汇编

Let ug denote the graded Lie algebra associated to the prounipotent radical of the relative Malcev completion of Ig defined by Hain [29] and let ug→hQ g be the natural homomorphism (here hQ g denotes the graded Lie algebra consisting of symplectic derivations, with positive degrees, of the Malcev Lie algebra of π1Σg). Determine whether this homomorphism is injective or not. In [80], we defined a series of secondary characteristic classes for the mapping class group. However there was ambiguity coming from possible odd dimensional stable cohomology classes of the mapping class group. Because of the result of Madsen-Weiss cited above, we can now eliminate the ambiguity and give a precise definition as follows. For each i, we constructed in [51][52] explicit group cocycles zi∈ Z2i(Mg; Q) which represent the i-th Mumford-Morita-Miller class ei by making use of the homomorphism Mg→U ⋊ Sp(2g, Z) constructed in [77] which extends the (first) Johnson homomorphism Ig→U. These cocycles are Mg-invariant by the definition. Furthermore we proved that such cocycles are unique up to coboundaries. On the other hand, as is well known, any odd class e2i-1 comes from the Siegel modular group Sp(2 g, Z) so that there is a cocycle z′ 2i-1∈ Z4i-2(Mg; Q) which comes from Sp(2 g, Z). This cocycle is uniquely defined up to coboundaries and Mg-invariant. Now consider the difference z2i-1-z′ 2i-1. It is a coboundary so that there exists a cochain yi∈ C4i-3(Mg; Q) such that δyi = z2i-1-z′ 2i-1. Since H 4i-3(Mg; Q) = 0 by [64] (in a suitable stable range), the cochain yi is well-defined up to coboundaries. Now let Kg be the kernel of the Johnson homomorphism so that we have an extension 1-→Kg-→Ig-→U-→1. (8) Recall that Johnson [43] proved that Kg is the subgroup of Mg generated by Dehn twists along separating simple closed curves on Σ g. The cocycle z′ 2i-1 is trivial on the Torelli group Ig while the cocycle z2i-1 (in fact any zi) vanishes on Kg. It follows that the restriction of the cochain yi toKg is a cocycle. Hence we obtain a cohomology class di = [yi|Kg]∈H 4i-3(Kg; Q). This cohomology class is Mg-invariant where Mg acts on H ∗(Kg; Q) via outer conjugations. This can be shown as follows. For any element ϕ∈M g, let ϕ∗(yi) be the cochain obtained by applying the conjugation by ϕ on yi. Since both cocycles z2i-1,z ′ 2i-1 areMg-invariant, we have δϕ∗(yi) = δyi. Hence ϕ∗(yi)-yi is a cocycle of Mg. By the result of [64] again, we see that ϕ∗(yi)-yi is a coboundary. Hence the restrictions of ϕ∗(yi) and yi toKg give the same cohomology class.

O / open | AMR 问题清单汇编

Find a point ρ∈ Hom(π, SL(2, C)) such that the closure of its orbit ModΣ· [ρ] meets both the image of the unitary characters Hom(π, SU(2)) and the closure QΣ of the quasi-Fuchsian characters. Homological actions. The action of ModΣ on the homology of Hom(π,G)/G furnishes another source of possibly interesting linear representations of ModΣ. With Neumann [51], we proved that for the relative SL(2, C)-character varieties of the one-holed torus and four-holed sphere, the action of ModΣ factors through a finite group. Atiyah-Bott [3] use infinite-dimensional Morse theory to analyze the algebraic topology of Hom(π,G)/G, when G is compact. For the nonsingular components their techniques imply that the ModΣ-action on the rational cohomology of Hom(π,G)/G factors through the symplectic representation of ModΣ on H ∗(Σ). In particular Biswas [9] proved that the Torelli group acts trivially on nonsingular components. In contrast, Cappell-Lee-Miller [17, 18] proved the surprising result that that the Torelli group acts nontrivially on the homology of the SU(2)-character variety when Σ is closed.

Problem 3.5 - Find explicit way of calculating d1(ϕ) for any given element ϕ ∈ Kg.

O / open | AMR 问题清单汇编

Find explicit way of calculating d1(ϕ) for any given element ϕ ∈ Kg. In particular, determine whether the Magnus representation Ig,1→GL(2g; Z[H]) of the Torelli group detectsd1 or not. Suzuki [103] proved that the Magnus representation of the Torelli group mentioned above is not faithful so that it may happen that the intersection of the kernel of the Magnus representation withKg is not contained in the kernel of d1. We may also ask whether the representation of the hyperelliptic mapping class group given by Jones [45], restricted to the intersection of this group withKg, detects d1 or not (cf. Kasahara [46] for a related work for the case g = 2). There are also various interesting works related to the class d1 such as Endo [14] and Morifuji [71] treating the hyperelliptic mapping class group, Kitano [54] as well as Hain and Reed [33]. Recently Biss and Farb [5] proved that the group Kg is not finitely generated for all g≥ 3 (K2 is known to be an infinitely generated free group by Mess [69]). However it is still not yet known whether the abelianization H1(Kg) is finitely generated or not (cf. Problem 2.2 of [80]). Finally we would like to mention that Kawazumi [50] is developing a theory of harmonic Mag- nus expansions which gives in particular a system of differential forms representing the Mumford-Morita-Miller classes on the universal family of curves over the moduli space Mg.

O / open | AMR 问题清单汇编

Is there a natural quotient complex of any one of the complexes discussed in §1 which might be useful for the construction of non-faithful representations of Mg? Let’s suppose that we have some answers to either Problem 3.1 or 3.2 or 3.5. At that moment, our instincts would lead us right back to a line of investigation that was successful many years ago when, in [4], we used the symplectic representation and found an invariant which distinguished inequivalent minimal Heegaard splittings. In the intervening years we suggested that our students try to do something similar with other representations, but that project failed. We propose it anew. Recall that a 3-manifold M may have one or more distinct equivalence classes of Heegaard splittings. It is known that any two become equivalent after some number of stabilizations. There are many interesting unanswered questions about the collection of all equivalence classes 10. 3-manifolds, Heegaard distance and mapping class groups 155 of Heegaard splittings of a 3-manifold, of every genus. Recall that the equivalence class of the Heegaard splitting H∪φH ′ is the double coset HφH inM.

Problem 3.6 - (Generalized word problem).

P / partially_solved | AMR 问题清单汇编

(Generalized word problem). Determine the subgroups H in Modg for which the generalized word problem is solvable. Give efficient algorithms to solve the generalized word problem for these subgroups. Find the optimal time bounds for such algorithms. Of course this problem is too broad to solve in complete generality; results even in special cases might be interesting. Some solutions to Problem 3.6 are given by Leininger-McReynolds 26 B. Farb in [LM]. We also note that Bridson-Miller (personal communication), extending an old result of Baumslag-Roseblade, have proven that any product of finite rank free groups has solvable generalized word problem with respect to any finitely presented subgroup. In light of this result, it would be interesting to determine whether or not there is a finitely presented subgroup of Mod g with respect to which the generalized word problem is not solvable. Distortion and quasiconvexity. There is a refinement of Problem 3.6. Let H be a finitely generated subgroup of a finitely generated group Γ. Fix finite generating sets on both H and Γ. This choice gives a word metric on both H and Γ, where dΓ(g,h) is defined to be the minimal number of generators of Γ needed to represent gh-1. Let N denote the natural numbers. We say that a function f: N-→ N is a distortion function for H in Γ if for every word w in the generators of Γ, if w represents an element w∈H then dH (1,w)≤f (dΓ(1,w)) In this case we also say that “ H has distortion f (n) in Γ.” It is easy to see that the growth type of f, i.e. polynomial, exponential, etc., does not depend on the choice of generators for either H or Γ. It is also easy to see that f (n) is constant if and only if H is finite; otherwise f is at least linear. It is proved in [F a1] that, for a group Γ with solvable word problem, the distortion of H in Γ is recursive if and only if H has solvable generalized word problem in Γ. For some concrete examples, we note that the center of the 3-dimensional integral Heisenberg group has quadratic distortion; and the cyclic group generated by b in the group ⟨a,b: aba-1 = b2⟩ has exponential distortion since anba-n =b2n.

Problem 3.6 - Study the double coset HφH inM, using new finite or infinite quotients of M.

O / open | AMR 问题清单汇编

Study the double coset HφH inM, using new finite or infinite quotients of M. In this regard we stress finite, because a principle difficulty when this project was attempted earlier was in recognizing the image of H in infinite quotients of M, however if the quotient is finite and not too big, it suffices to know generators of H⊂M. Since a presentation for H was found by Waynryb in [51], we can compute the associated subgroup. Some of the open questions which might be revealed in a new light are: (1) How many times must one stabilize before two inequivalent Heegaard splittings become equivalent? (2) How can we tell whether a Heegaard splitting is not of minimal genus? (3) How can we tell whether a Heegaard splitting is stabilized? (4) Are any of the representations that we noted earlier useful in answering (1), (2) or (3) above? While we have stressed the search for good working quotients of Mg, we should not forget that in the case of homology spheres, we have already pointed out that any homology sphere may be defined by a Heegaard splitting with the Heegaard glueing map (now redefined with a new ‘base point’) ranging over Ig. Even more, as was proved earlier, Morita has shown in [36] that it suffices to let the glueing map range over Kg. This leads us to ask:

Problem 3.7 - (Distortion).

P / partially_solved | AMR 问题清单汇编

(Distortion). Find the possible distortions of subgroups in Modg. In particular, compute the distortions of Ig. Determine the asymptotics of the distortion of Ig(k) as k→∞. Is there a subgroup H <Modg that has precisely polynomial distortion of degree d> 1? There are some known results on distortion of subgroups in Mod g. Convex cocompact sub- groups (in the sense of [FMo]) have linear distortion in Mod g; there are many such examples where H is a free group. Abelian subgroups of Mod g have linear distortion (see [FLMi]), as do subgroups corresponding to mapping class groups of subsurfaces (see [MM2, Ham]). I would guess that Ig has exponential distortion in Mod g. A first step to the question of how the distortion of Ig(k) in Mod g behaves as k→∞ would be to determine the distortion of Ig(k + 1) in Ig(k). The “higher Johnson homomorphisms” (see, e.g., [Mo3]) might be useful here. A stronger notion than linear distortion is that of quasiconvexity. Let S = S-1 be a fixed generating set for a group Γ, and let π: S∗→ Γ be the natural surjective homomorphism from the free monoid on S to Γ sending a word to the group element it represents. Let σ: Γ →S∗ be a (perhaps multi-valued) section of π; that is, σ is just a choice of paths in Γ from the origin to each g∈ Γ. We say that a subgroup H <Γ is quasiconvex (with respect to σ) if there exists K >0 so that for each h∈ H, each path σ(h) lies in the K-neighborhood of H in Γ. Quasiconvexity is a well-known and basic notion in geometric group theory. It is easy to see that if H is quasiconvex with respect to some collection of quasigeodesics then H has linear distortion in Mod g (see [F a1]). 2. Some problems on mapping class groups and moduli space 27

O / open | AMR 问题清单汇编

Are there quotients of Ig orKg in which the intersection of either Ig orKg with the handlebody group Hg is sufficiently tractible to allow one to study the double cosets: (Ig∩Hg)(φ)(Ig∩Hg), where φ∈I g, or (Kg∩Hg)(φ)(Kg∩Hg), where φ∈K g? In regard to Problem 3.7 we note that in [36] Morita was seeking to understand how topological invariants of 3-manifolds might lead him to a better understanding of the representations of Ig andKg, but he did not ask about the potential invariants of Heegaard splittings that might, at the same time, be lurking there.

Problem 4 - Does the recipe in Theorem 4 give virtually all pA maps?

S / solved | AMR 问题清单汇编

Does the recipe in Theorem 4 give virtually all pA maps? That is, given a pA map f, is there some iterate fn, for n≥ 1, so that fn arises from the recipe? (This question from [23,25] is related [10] to the Ehrenpreis Conjecture, our Problem 14.) In relation to Problem 4, let us mention that there are still other descriptions of pA maps up to iteration, for instance by Mosher [42] and in joint work of the author with Papadopoulos [45]; these descriptions are combinatorial rather than in terms of Dehn twists. For a fixed surface F, consider the set of logarithms of dilatations of all pA maps supported on F. This characteristic “spectrum” Σ(F)⊆ R>0 of F is precisely the Teichm¨ uller geoedsic length spectrum of Riemann’s moduli space M(F). The spectrum Σ(F) is discrete. (In fact, dilatations occur as spectral radii of integral-linear Perron-Frobenius symplectomorphisms in a range of dimensions bounded above and below in terms of the topological type of F.)

Problem 4.10 - (Algorithmic Schottky problem).

O / open | AMR 问题清单汇编

(Algorithmic Schottky problem). Give an algorithm, in the sense of complexity theory over R, which takes as input a 2g×2g symplectic matrix representing a principally polarized abelian variety, and as output tells whether or not that torus lies in the period locus. One might also fix some ϵ = ϵ(g), and then ask whether or not a given principally polarized abelian variety lies within ϵ (in the locally symmetric metric on Ag) of the period locus. It should be noted that S. Grushevsky [Gr] has made the KP-equations solution to the Schot- tky problem effective in an algebraic sense. This seems to be different than what we have just discussed, though. We now address the question of what the Schottky locus looks like from far away. To make this precise, let Cone(Ag) denote the tangent cone at infinity (defined in (10) above) of the locally symmetric Riemannian orbifold Ag. Hattori [Hat] proved that Cone(Ag) is homeomorphic to the open cone on the quotient of the Tits boundary of the symmetric space Sp(2 g, R)/U(g); indeed it is isometric to a Weyl chamber in the symmetric space, which is just a Euclidean sector of dimension g.

09757 | AMR-109-0048

Problem 4.11 - (Coarse Schottky problem).

P / partially_solved | AMR 问题清单汇编

(Coarse Schottky problem). Describe, as a subset of a g-dimensional Euclidean sector, the subset of Cone(Ag) determined by the Schottky locus in Ag. Points in Cone(Ag) are recording how the relative sizes of basis vectors of the tori are changing; it is precisely the “skewing parameters” that are being thrown away. It doesn’t seem unreasonable to think that much of the complexity in describing the Schottky locus is coming precisely from these skewing parameters, so that this coarsification of the Schottky problem, unlike the classical version, may have a reasonably explicit solution. There is a well-known feeling that the Schottky locus is quite distorted in Ag. Hain and Toledo (perhaps among others) have posed the problem of determining the second fundamental form of the Schottky locus, although they indicate that this would be a rather difficult computation. We can coarsify this question by extending the definition of distortion of subgroups given in Subsection 3.2 above to the context of subspaces of metric spaces. Here the distortion of a subset S in a metric space Y is defined by comparing the restriction of the metric dY to S versus the induced path metric on S.

Problem 4.14 - (J.

O / open | AMR 问题清单汇编

(J. Przytycki) (i) Find generators of S4,∞(S3, R). (ii) For which parameters of the (4,∞) skein and framing relations, trivial links are linearly independent in S4,∞(S3; R)? (iii) For which parameters of the (4,∞) skein and framing relations, the trivial knot is not representing a torsion element of S4,∞(S3, R)? A generalization of the Montesinos-Nakanishi conjecture [345] said that S4,∞(S3, R) is generated by trivial links and that the (4,∞) skein module (suit- ably defined) for n-tangles is generated by ∏ n-1 i=1 (3i +1) certain basic n-tangles. This would give a generating set for the (4,∞) skein module of S3 or D3 with 2 n boundary points (for n-tangles). However, the Montesinos-Nakanishi 3-move conjecture has been disproved by M.Dabkowski and J.H.Przytycki in February 2002 [99] and [342]. Therefore ∏ n-1 i=1 (3i + 1) is only the lower bound for the number of generators. In [345] we extensively analyze the possibilities that triv ial links are linearly independent; if b∞ = 0, then this may happen only if b0b1 = b2b3. These leads to the following conjecture (cases (1)-(2)):

Problem 4.2 - .

P / partially_solved | AMR 问题清单汇编

. Find an analogue of Theorem 4.1 for topological manifolds, and relate it to surgery and pseudo-isotopy theory. Waldhausen's functor A(X) is the algebraic K-theory of the "ring" Ω ∞S∞(ΩX+). It is a ho- motopy theoretic construction which, quite explicitly, contains information about both Diff(X× I,∂X ×I∪X× 0) and Top(X×I,∂X ×I∪X× 0) where X is a compact d-manifold in a range of dimensions that increase with d, cf [20], [21]. Less explicitly A(X) also relates to Diff(X) and Top(X), cf. [22]. The topological cyclic homology functor TC(X), introduced in [1], is an enriched version of Connes' cyclic homology. A(X) maps to TC(X) via the cyclotomic trace, but TC(X) and the associated functor for rings (or linear categories) is of interest in its own right, cf. [9]. The p-adic completion TC(X)∧ p can be expressed in terms of more standard constructions in homotopy theory involving the free loop space. For X =pt, TC(pt)∧ p≃ (Ω∞S∞× Ω∞-1CP ∞ -1)∧ p. (6)

Problem 4.2 - Determine whether or not H•(Tg; Z[1/2])- is always a finitely generated Z[1/2]-module.

S / solved | AMR 问题清单汇编

Determine whether or not H•(Tg; Z[1/2])- is always a finitely generated Z[1/2]- module. Does the infinite topology of Tg comes from Jg? To get one's hands on H•(Tg)-, it is necessary to better understand the topology of T c g or Sc g. Since Jc g is a Stein space, so is Sc g. Hamm's result [9] (see also [5, p. 152]) implies that Sc g has the homotopy type of a CW-complex of dimension at most 3 g- 3. Since Sc g is not a rational homology manifold when g≥ 3, it is probably most useful to study the topology of the manifold T c g as Poincar´ e duality will then be available. 8

Problem 4: - Does the above definition of a convex cocompact subgroup of Mg,m coincide with the definition of Farb and Mosher in [...

P / partially_solved | AMR 问题清单汇编

Does the above definition of a convex cocompact subgroup of Mg,m coincide with the definition of Farb and Mosher in [FMo]? Is the natural extension of such a group Γ by the fundamental group π1(S) of S word hyperbolic? Is there a convex cocompact subgroup of Mg,m which is isomorphic to the fundamental group of a closed surface of genus at least 2? A particular interesting class of subgroups of Mg,m arise from Veech surfaces. These surfaces are the projections to moduli space of the stabilizer of a complex geodesic in Teichm¨ uller space (which is a maximal embedded complex disc in the Teichm¨ uller space viewed as a bounded domain in C3g-3+m) with the additional property that this stabilizer is a lattice in PSL (2, R). Veech surfaces are surfaces of finite type with isolated singularities embedded in moduli space; they are never closed [V]. Thus their corresponding subgroup of Mg,m contains a free group of finite index with a distinguished family of conjugacy classes corresponding to the cusps of the curve. Veech surfaces have many beautiful algebraic and geometric properties (see e.g. [McM1], [McM2]). Elementary constructions of such surfaces and their coresponding subgroups of Mg,m are for example discussed in [L]. Veech surfaces can also be used to construct explicit subgroups of mapping class groups with prescribed geometric properties. A particularly beautiful result along this line was recently obtained by Leininger and Reid [LR].

Problem 5.11 - (Torelli finiteness).

O / open | AMR 问题清单汇编

(Torelli finiteness). Determine the maximal number f (g) for which there is a K(Ig, 1) space with finitely many cells in dimensions ≤f (g). Here is what is currently known about Problem 5.11: (1) f (2) = 0 since I 2 is not finitely generated (McCullough-Miller [McM]). (2) f (3)≤ 3 (Johnson-Millson, unpublished, referred to in [Me]). (3) For g≥ 3, combining Johnson's finite generation result [Jo2] and a theorem of Akita (Theorem 5.13 below) gives 1 ≤f (g)≤ 6g- 5. One natural guess which fits with the (albeit small amount of) known data is that f (g) = g-2. As a special case of Problem 5.11, we emphasize the following, which is a folklore conjecture.

Problem 5.15 - (Explicit cycles).

P / partially_solved | AMR 问题清单汇编

(Explicit cycles). Explicitly construct infinitely many linearly independent cy- cles in H∗(Ig, Q) and H∗(Kg, Q). So, we are still at the stage of trying to find explicit nonzero cycles. In a series of papers (see [Jo1] for a summary), Johnson proved the quite nontrivial result: H 1(Ig, Z)≈∧3H H ⊕B2 (16) where B2 consists of 2-torsion. While the ∧3H/H piece comes from purely algebraic consider- ations, the B2 piece is "deeper" in the sense that it is purely topological, and comes from the Rochlin invariant (see [BC] and [Jo1]); indeed the former appears in H1 of the "Torelli group" in the analogous theory for Out(Fn), while the latter does not. 42 B. Farb

Problem 5.16 - Determine the subalgebras of H ∗(Ig,K), for K = Q and K = F2, generated by H 1(Ig,K).

O / open | AMR 问题清单汇编

Determine the subalgebras of H ∗(Ig,K), for K = Q and K = F2, generated by H 1(Ig,K). Note that H ∗(Ig,K) is a module over Sp(2 g,K). When K = Q this problem has been solved in degree 2 by Hain [Ha3] and degree 3 (up to one unknown piece) by Sakasai [Sa]. Symplectic representation theory (over R) is used as a tool in these papers to greatly simplify computations. When K = F2, the seemingly basic facts one needs about representations are either false or they are beyond the current methods of modular representation theory. Thus computations become more complicated. Some progress in this case is given in [BF a2], where direct geometric computations, evaluating cohomology classes on abelian cycles, shows that each of the images of σ∗:H 2(B3, F2)→H 2(Ig, F2) (σ|Kg)∗:H 2(B2, F2)→H 2(Kg, F2) has dimension at least O(g4).

Problem 5.20 - (Hain for Aut(Fn)).

O / open | AMR 问题清单汇编

(Hain for Aut(Fn)). Give an explicit finite presentation for the Malcev Lie AlgebraL(IAn), where IAn is the group of automorphisms of the free group Fn acting trivially on H1(Fn, Z). There is a great deal of interesting information at the prime 2 which Hain’s theorem does not address, and indeed which remains largely unexplored. While Hain’s theorem tells us that reduction mod 2 gives us a large subalgebra of L2(Ig,1) coming from L0(Ig,1), the Lie algbera L2(Ig,1) over F2 is much bigger. This can already be seen from (16). As noted above, the 2-torsion B2 exists for “deeper” reasons than the other piece of H1(Ig,1, Z), as it comes from the Rochlin invariant as opposed to pure algebra. Indeed, for the analogous “Torelli group” IA n for Aut(Fn), the corresponding “Johnson homomorphism” gives all the first cohomology. Thus the 2-torsion in H 1(Ig, Z) is truly coming from 3-manifold theory.

09804 | AMR-109-0069

Problem 5.25 - (Presentation for level L structures).

O / open | AMR 问题清单汇编

(Presentation for level L structures). Give an explicit finite presentation for Modg[L]. Once one has such a presentation, it seems likely that it would fit well into the framework of Pitsch’s proof [Pi] that rank(H2(Modg,1, Z))≤ 1 for g≥ 4. Note that Pitsch’s proof was extended to punctured and bordered case by Korkmaz-Stipsicsz; see [Ko]. What Pitsch does is to begin with an explicit, finite presentation of Mod g,1, and then to apply Hopf’s formula for groups Γ presented as the quotient of a free group F by the normal closure R of the relators: H2(Γ, Z) = R∩ [F,F] [F,R] (17) In other words, elements of H2(Γ, Z) come precisely from commutators which are relators, except for the trivial ones. Amazingly, one needs only write the form of an arbitrary element of the numerator in (17), and a few tricks reduces the computation of (an upper bound for) space of solutions to computing the rank of an integer matrix. In our case this approach seems feasible, especially with computer computation, at least for small L. Of course one hopes to find a general pattern.

Problem 5.5 - Explore ΓC for other free subgroups G< MCG (S), for example free subgroups generated by high powers of Dehn twists ab…

O / open | AMR 问题清单汇编

Explore ΓC for other free subgroups G< MCG (S), for example free subgroups generated by high powers of Dehn twists about a pair of filling curves. IfG is not free then [Mos03a] contains a result more general than Theorem 5.3, with QI(Γ G) replaced by a group QI f (ΓG) constructed from quasi-isometries Γ G→ ΓG which coarsely preserve the family of cosets of π1(S) < ΓG. The point of G being free is that in this case one can use methods of coarse algebraic topology to prove that QI f (ΓG) = QI(Γ G); see e.g. [FM00]. In the case that G =MCG (S) covered in Theorem 5.2, Whyte's homological methods are used to prove that QI f (ΓG) = QI(Γ G). One might be able to use Whyte's homological methods for other subgroups G <MCG (S), particularly when G is a Bieri-Eckmann duality group which is not a Poincar´ e duality group, such as G =MCG (S) [Har86]. Unfortunately, none of these methods will work when G is a Leininger-Reid group, because in this case, G is a 2-dimensional Poincar´ e duality group, which rules out the methods of [FM00] 16. Problems in the geometry of surface group extensions 269 as well as Whyte's homological methods. We do not have any idea of how to overcome this obstacle. Nonetheless it should still be interesting to calculate Γ C = QI f (ΓG) for a Leininger-Reid subgroup G.

Problem 5.6 - Find H1(Ig(k), Z) for all k≥ 2.

P / partially_solved | AMR 问题清单汇编

Find H1(Ig(k), Z) for all k≥ 2. Generating sets for Ig. One difficulty in working with Ig is the complexity of its generating sets: any such set must have at least 1 3 [4g3-g] elements since Ig has abelian quotients of this rank (see [Jo5], Corollary after Theorem 5). Compare this with Mod g, which can always be generated by 2 g + 1 Dehn twists (Humphries), or even by 2 elements (Wajnryb [W a])! How does one keep track, for example, of the (at least) 1330 generators for I 10? How does one even give a usable naming scheme for working with these? Even worse, in Johnson's proof of finite generation of Ig (see [Jo2]), the given generating set has O(2g) elements. The following therefore seems fundamental; at the very least it seems that solving it will require us to understand the combinatorial topology underlying Ig in a deeper way than we now understand it.

09812 | AMR-109-0054

Problem 5.7 - (Cubic genset problem).

S / solved | AMR 问题清单汇编

(Cubic genset problem). Find a generating set for Ig withO(gd) many elements for some d≥ 3. Optimally one would like d = 3. In fact in §5 of [Jo2], Johnson explicitly poses a much harder problem: for g≥ 4 can Ig be generated by 1 3 [4g3-g] elements? As noted above, this would be a sharp result. Johnson actually obtains this sharp result in genus three, by finding ([Jo2], Theorem 3) an explicit set of 35 generators for Ig. His method of converting his O(2g) generators to O(g3) becomes far too unwieldy when g >3. One approach to Problem 5.7 is to follow the original plan of [Jo2], but using a simpler generating set for Mod g. This was indeed the motivation for Brendle and me when we found in [BF a1] a generating set for Mod g consisting of 6 involutions, i.e. 6 elements of order 2. This bound was later improved by Kassabov [Ka] to 4 elements of order 2, at least when g≥ 7. Clearly Modg is never generated by 2 elements of order two, for then it would be a quotient of the infinite dihedral group, and so would be virtually abelian. Since the current known bounds are so close to being sharp, it is natural to ask for the sharpest bounds.

O / open | AMR 问题清单汇编

A version of the previous problem, in which the complexity measure is not purely topological: namely, it is the lowest number of critical points of Morse functions defined by restrictions of linear functions ${\mathbb{R}}^{N}\to{\mathbb{R}}$ to our varieties. $($Correspondingly, the surgeries of the variety affecting this measure should be not only those of topological nature but also include bifurcations of the dual variety$)$.

Problem 6 - Calculate the topological type (PL-homeomorphism, homotopy, homology...

O / open | AMR 问题清单汇编

Calculate the topological type (PL-homeomorphism, homotopy, homology... type) of the Arc-complexes. The first non-trivial case is the calculation of the topological type of the PL-manifolds Arc(M) for the four type 1 surfaces M. Arc complexes as stratified spaces conjecturally have specific singularities and topology described recursively as follows. A PL sphere is a type zero space. A closed, connected, and simply connected manifold is a type one space provided it occurs among a list of four specific such (non-spherical) manifolds of respective dimensions 5,7,7, and 9, namely, the arc complexes of the four type one surfaces. For n> 1, define a type n space to be a finite polyhedron, defined up to PL-isomorphism, so that the link of each vertex in any compatible triangulation is PL isomorphic to an iterated suspension of the join of at most two spaces of type less than n. By Theorem 5, many links of simplices are indeed of this type, and we conjecture that any arc complex is of some finite type. (As explained in [46], a specific collapsing argument in the “calculus of mapping cylinders” would give a proof a of this conjecture.) 112 R. Penner The non-Hausdorff space PF (F)/PMC (F) thus contains the stratified space Arc(F) as an open dense subset, explaining one classical (i.e., non-quantum) aspect to Problem 1. In light of the stratification of Arc-complexes in general, one might hope to apply techniques such as [1,34] to address parts of Problem 6.

Problem 6 - Find special features of the monodromy of algebraic surfaces.

O / open | AMR 问题清单汇编

Find special features of the monodromy of algebraic surfaces. There is some good motivation for this coming from at least three directions • The problem includes (in principle) the well-known problem of describing possible fun- damental groups of algebraic surfaces. • One famous constraint is the “hard Lefschetz” property, which has a well-known trans- lation into the action of the monodromy on homology. • From the Seiberg-Witten theory we know that there are strong restrictions on the basic classes of algebraic surfaces, and these can be translated into the TLP point of view along the lines of [6], [13].

Problem 6.1 - (Actions on buildings).

S / solved | AMR 问题清单汇编

(Actions on buildings). Determine all isometric actions ψ: Mod g→ Isom(Xn), whereXn is an n-dimensional Euclidean building, and n is sufficiently small compared to g. For example, one would like conditions under which ψ has a global fixed point, that is, a point x∈ Xn such that ψ(Modg)·x = x. One method to attack this problem is the so-called “Helly technique” introduced in [F a4]. Using standard CAT(0) methods, one can show that each Dehn twist Tα in Mod g has a nontrivial fixed set Fα under the ψ-action; Fα is necessarily convex. Considering the nerve of the collection {Fα} gives a map Cg→ Xn from the complex of curves to Xn. Now Cg has the homotopy type of a wedge of spheres (see, e.g., [Iv1]), while Xn is contractible. Hence the spheres in the nerve must be filled in, which gives that many more elementsψ(Tα) have common fixed points. The problem now is to understand in an explicit way the spheres inside Cg.

09833 | AMR-109-0074

Problem 6.5 - (The sections problem).

O / open | AMR 问题清单汇编

(The sections problem). Determine those subgroups H ≤ Modg for which π has a section over H. Do this as well with Homeo+(Σg) replaced by various subgroups, such as Diffr(S) with r = 1, 2,..., ∞,ω; similarly for the group of area-preserving diffeomorphisms, quasiconformal homeomorphisms, etc.. Answers to Problem 6.5 are known in a number of cases. (1) When H is free then sections clearly always exist over H. (2) Sections to π exist over free abelian H, even when restricted to Diff ∞(Σg). This is not hard to prove, given the classification by Birman-Lubotzky-McCarthy [BLM] of abelian subgroups of Mod g. (3) Sections exist over any finite group H <Modg, even when restricted to Diff ω(Σg). This follows from the Nielsen Realization Conjecture, proved by Kerckhoff [Ke], which states that any such H acts as a group of automorphisms of some genus g Riemann surface. 2. Some problems on mapping class groups and moduli space 49 (4) In contrast, Morita showed (see, e.g., [Mo5]) that π does not have a section with image in Diff 2(Σ2) over all of Mod g when g≥ 5. The C2 assumption is used in a crucial way since Morita uses a putative section to build a codimension 2 foliation on the universal curve over Mg, to whose normal bundle he applies the Bott vanishing theorem, contradicting nonvanishing of a certain (nontrivial!) Miller-Morita-Mumford class. It seems like Morita’s proof can be extended to finite index subgroups of Mod g. (5) Markovic [Mar] has recently proven that H = Mod g does not even have a section into Homeo(Σg), answering a well-known question of Thurston. As is usual when one studies representations of a discrete group Γ, one really desires a theorem about all finite index subgroups of Γ. One reason for this is that the existence of torsion and special relations in a group Γ often highly constrains its possible representations. Markovic’s proof in [Mar] uses both torsion and the braid relations in what seems to be an essential way; these both disappear in most finite index subgroups of Mod g. Thus it seems that a new idea is needed to answer the following.

Problem 6: - For a closed surface of genus g≥ 3, is the Torelli subgroup of Mg,m undistorted?

S / solved | AMR 问题清单汇编

For a closed surface of genus g≥ 3, is the Torelli subgroup of Mg,m undistorted? More generally, find a distorted finitely generated subgroup of Mg,m. The splitting sequences on the complex of train tracks can be used to investigate the large-scale geometric behavior of the mapping class group. Note that such a splitting sequence (τi) is determined by an initial train track and for each i by a choice of a splitting move among a uniformly bounded number of possibilities which transforms the train track τi to the train track τi+1. In other words, it is possible to treat splitting sequences and hence uniform quasi-geodesics inMg,m in an algorithmic way. 14. Geometric properties of the mapping class group 243 Algorithmic calculations in a finitely generated group Γ are very intimately related to two basis decision problems which go back to Dehn and can be formulated as follows (see Chapter III.Γ.1 in [BH]). Word problem: A word w in a fixed system of generators for Γ is given. One is required to find a method to decide in a finite number of steps whether or not this word represents the identity in Γ. Conjugacy problem: Two elements g,h∈ Γ are given. A method is sought to decide in a finite number of steps whether or not the elements g,h are conjugate, i.e. whether there is some u∈ Γ such that h =ugu-1. In the last decade of the twentith century, Epstein, Cannon, Holt, Levy, Paterson, Thurston [E] formulated a property for finitely generated groups which ensures that these problems can be solved in controlled time. Namely, a biautomatic structure for a finitely generated group Γ consists of a finite alphabet A, a (not necessarily injective) map π:A→ Γ and a regular language L over the alphabet A with the following properties. The set π(A) generates Γ, and there is an inversion ι: A→ A (i.e. ι2 = Id) with π(ιa) = π(a)-1 for all a∈ A. In particular, π(A) is a symmetric set of generators for Γ. Via concatenation, every word w in the alphabet A is mapped by π to a word in the generators π(A) of Γ and hence it defines an element π(w)∈ Γ. We require that the restriction of the map π to the set of all words from the language L maps L onto Γ. For all x,y∈A and each word w∈L of length k≥ 0, the word xwy defines via the projection π a path s: [0,k + 2] → Γ. By assumption, there is a word w′∈L of length ℓ >0 with π(w′) = π(xwy). Let s′: [0,ℓ]→ Γ be the corresponding path in Γ; we require that the distance in Γ between s(i) and s′(i) is bounded by a universal constant which neither depends on i nor on the choice of x,y,w,w ′. Extending earlier work of Mosher [M1], in [H1] the complex of train tracks and its algorithmic properties are used to show.

Problem 7.3 - Compute L(Modg) explicitly for small g≥ 2.

P / partially_solved | AMR 问题清单汇编

Compute L(Modg) explicitly for small g≥ 2. In principle L(Modg) can be computed for any given g. The point is that one can first bound the degree of L(Modg), then give bounds on the smallest possible value λ(α), where α ranges over all algebraic integers of a fixed range of degrees, and λ(α) denotes the largest root of the minimal polynomial of α. One then finds all train tracks on Σ g, and starts to list out all pseudo-Anosovs. It is possible to give bounds for when the dilatations of these become large. Now one tries to match up the two lists just created, to find the minimal dilatation pseudo-Anosov on Σ g. Of course actually following out this procedure, even for small g, seems to be impracticable.

(J.E. Andersen) If such an expansion exists, understand how it is related to the expansion of Ohtsuki and the expansion of Habiro. It will of course be important to establish, that an expansio n of this type ex- ists, however, of far greater importance will be to give inde pendent topological meaning to the many resulting new invariants, e.g. to prove t hat the phases are the Chern-Simons values cj. From the discussion above on the semi-classical approximation we derive the following conjecture:

Problem 7: - Is the mapping class group linear?

P / partially_solved | AMR 问题清单汇编

Is the mapping class group linear? A locally compact group Γ is said to satisfy the Haagerup approximation property or is a-T- menable if there exists a continuous, isometric action α of Γ on some affine Hilbert space H which is metrically proper. This means that for all bounded subsets B ofH, the set {g∈ Γ|α(g)B∩B=∅} is relatively compact in Γ. There are other equivalent characterizations of this property (see [CCJJV]) which can be viewed as a strong negation of the (perhaps more widely know) property (T) of Kazhdan. The class of a-T-menable groups contains for example all amenable groups, Coxeter groups and the isometry groups of real and complex hyperbolic spaces. It is also known that for a-T-menable groups the Baum-Connes conjecture holds (see [CCJJV]).

Problem 8 - [Contributed by the referee] Does Theorem 5 say anything about the structure of the end of Riemann’s moduli space?

O / open | AMR 问题清单汇编

[Contributed by the referee] Does Theorem 5 say anything about the structure of the end of Riemann’s moduli space? For instance, what is the homology near the end? Take the one-point compactification F × of F = Fs g,r, where all of the s≥ 0 punctures of F are identified to a single point in F ×, so F × =F if and only if s≤ 1. Let ∂ denote the boundary mapping of the chain complex {Cp(Arc): p≥ 0} of Arc = Arc(F). Suppose that α is an arc family in F with corresponding cell σ[α]∈Cp(Arc). A codimension-one face of σ[α] of course corresponds to removing one arc from α, and there is a dichotomy on such faces σ[β] depending upon whether the rank of the first homology of F ×-∪β agrees with or differs by one from that of F ×-∪α. This dichotomy decomposes ∂ into the sum of two operators ∂ =∂1 +∂2, where ∂2 corresponds to the latter case. The operators ∂1,∂ 2 are a pair of anti-commuting differentials, so there is a spectral sequence converging to H∗(Arc) corresponding to the bi-grading E0 u,v ={chains on σ[α]∈Cp(Arc): v =-rank(H1(Fα)) and u =p-v}, where ∂1:E0 u,v→E0 u-1,v and the differential of the E0 term is ∂2:E0 u,v→E0 u,v-1. It is not quite fair to call it a problem, nor a theorem since the argument is complicated and has not been independently checked, but we believe that this spectral sequence collapses in its E1-term to its top horizontal row except in dimension zero. Thus, the homology of Arc is the ∂1-homology of the ∂2-kernels in the top row, and on the other hand, it follows from [31] that the∂1-homology of the top row itself agrees with that of uncompactified Riemann’s moduli space M(F) As discussed in [30,46], the stratified structure of the arc complexes for bordered surfaces gives a corresponding stratified structure to A(F) for punctured F. This may be enough to re-visit the calculations of [19] and [16,22] with an eye towards avoiding technical difficulties with the Deligne-Mumford compactification ¯M(F).

Problem 8.1 - Determine the image as well as the cokernel of the homomorphism (15) explicitly.

O / open | AMR 问题清单汇编

Determine the image as well as the cokernel of the homomorphism (15) explic- itly. Note that Hain [29] proved that the image of (15), after tensored with Q, is precisely the Lie subalgebra generated by the degree 1 part. However it is unclear which part of hQ g,1 belongs to this Lie subalgebra. In relation to this problem, Oda predicted, in the late 1980’s, that there should arise “arith- metic obstructions” to the surjectivity of Johnson homomorphism. More precisely, based on the theory of Ihara in number theory which treated mainly the case g = 0,n = 3, he expected that the absolute Galois group Gal(Q/Q) should “appear” in hg,1⊗ Zℓ outside of the geometric part and which should be Sp-invariant for any genus g and for any prime ℓ. In 1994, Nakamura [86] 22. Cohomological structure of the mapping class group and beyond 367 proved, among other results, that this is in fact the case (see also Matsumoto [65]). This was the second obstruction to the surjectivity of Johnson homomorphism, the first one being the traces in [76]. This raised the following problem.

Problem 8.12 - (T.

P / partially_solved | AMR 问题清单汇编

(T. Kerler) [Cyclotomic integer TQFT's] (1) Find explicit/computable bases for the Vp(Σ g) as free modules over Z[ζp]. (2) Show that Vp can be extended to all cobordisms as a half-projective TQFT with x = (ζp- 1) p-3 2 ∈ R = Z[ζp]. (3) Determine the structure of the V [j] p (M) and in how far they have lifts from Fp to Z, analogous to the Ohtsuki invariants for closed 3-manifold s. (4) Find a universal TQFT that combines all Vp, at least perturbatively, into one. In the case of p = 5 the program for items (1)-(3) has been mostly carried out in [213], for primes p≥ 7 not much is known though. Some explicit bases have been found for genus g = 1 by Gilmer, but the situation for higher genera g≥ 3 is unknown. An immediate application of item (2) is that the quantum order, as introduced in [92], is also an upper bound for the cu t-number of a 3-manifold. A closely related statement for (2) would also y ield a very different proof for the fact that the Ohtsuki invariants are of finite ty pe. In item (3) the "lift" must depend on p since the dimensions of the vector spaces do, and must also involve further quotients that arise since the irreduc ible TQFT's over Z do not match the required dimensions either, but they become reducible when reduced to Fp. Item (4) is rather vague at this point, indicating for some s ort of infinite filtered space with finite graded components. Any TQFTV: Cob→ R-mod implies a sequence of representation V[g]: Γ g→ GLR(V(Σ g)) of the mapping class groups. We say that a TQFT is homological if each of these representations factors through the quotie nt Γ g-: Sp(2g, Z) (given by the action on H1(Σ g)), and we say it is strictly homological if each of the Sp(2 g, Z)-representations is algebraic, i.e. either faithful or ze ro. A par- ticular example of strictly homological TQFT's over R = Z are the Lefschetz componentsV (j) of the Frohman-Nicas TQFT, see [128, 214]. From these we can generate a larger family Q 0 of such TQFT's by taking all direct sums of V (j) 's. For example all the TQFT's constructed in [110] lie in Q 0. An even larger family Q∗ is found by taking also tensor products and their irreducibl e summands.

09875 | AMR-103-0159

Problem 8.13 - (T.

O / open | AMR 问题清单汇编

(T. Kerler) [Homological TQFT's] (1) Find the irreducible components and ring structure (w.r.t ⊕ and⊗) of Q∗. (2) Determine whether all strictly homological TQFT's lie in Q ∗. (3) Identify the homological TQFT's that arise from the gauge th eory of higher rank groups (such as P SU (n) in [129]) with elements in Q ∗. (4) Identify the irreducible factors of the constant orders V [0] p of the cyclo- tomic integer expansion of the Reshetikhin-Turaev theory w ith elements in Q∗. The first item is in some sense about finding the representatio n ring of Sp(2, Z)× Sp(4, Z)×...× Sp(2g, Z)×... equipped with further generators and relations given by the standard handle attachments. The constraints g iven by the latter may be just good enough to ensure that the answer to item (2) is positive. The application of (3) is a better understanding and possibl y a closed form for the polynomials from [129] that express the P SU (n)-invariants in terms of the coefficients of the Alexander polynomial. Evidence seems to s uggest that the TQFT's from (4) stem from p-3 2 -fold symmetric products of elements in Q 0. A plausible corollary would be that for a closed manifold wit h b1(M)≥ 1 we have Vp(M) = (ζp- 1) p-3 2 P p-3 2 (λCW L(M)) + O((ζp- 1) p-1 2), (46) where λCW L is the Casson-Walker-Lescop invariant, and Pj is a polynomial of degree j with integer coefficients. (Note our normalization Vp(S3) = 1). As remarked in [212] the identity in (46) is true for p = 5 and general M with b1(M)≥ 1. Moreover, work in progress shows that (46) holds also for g eneral p if M is a torus-bundle over a circle. The homological TQFT's are the starting point for a more gene ral, pertur- bative view point on TQFT's that should parallel and extend t hat of the fi- nite type theory of homology-3-spheres. At least for fixed p one can under- stand, for example, the Reshetikhin-Turaev theory as defor mation of the Q ∗ - theories. The notion that is somewhat parallel to that of fini te type for closed 3-manifolds is what we shall call finite length. More precisely, the representa- tionsV[g]: Γ g→ GLR(V(Σ g)) of the mapping class groups extend linearly to homomorphismsV[g]: Z[Γ g]→ EndR(V(Σ g)). Denote by IIg⊂ Z[Γ g] the aug- mentation ideal of the Torelli group. The length ofV is the maximal L∈ N such thatV[g]((IIg)L+1) = 0. Clearly, the L = 0-theories are just the homological ones. The L = 1-theories can be thought of as elements of some Ext(V,W) with V,W∈ Q ∗. Restricted to representations of the Γ g 's they factor (in char= 2) through the Johnson-Morita-homomorphism Γ g→ ⋀ 3 H1(Σ g) ⋊ Sp(2g, Z), for which such extension are explicitly constructible [211].

Problem 8.14 - (T.

O / open | AMR 问题清单汇编

(T. Kerler) [Length = 1 TQFT's] (1) Describe and construct algebraic L = 1 -extensions of Γ g -representations to TQFT's, preferably as "simple" generalizations of the Fr ohman-Nicas- U (1)-theory. (2) Produce a classification of L = 1 -TQFT's in the sense of an extension theory of Q ∗. (3) Identify the Γ g -representations on relative SU (2)-moduli space from [77] with these TQFT's, and find similar, higher rank theories. (4) Identify the V [0] p as L = 1 -theories, if possible. The conceivable generalizations of the TQFT construction o f Frohman and Nicas described in (1) include using different, possibly non -compact gauge groups instead of U (1) and using more refined versions of intersection homolo- gies for stratified moduli spaces. Given the theory for Q ∗ the solution to item (2) will lead to well defined problems in sp-invariant theory. Constructions of L = 1-theories follow the schemes from (1) and (3). The identifi cation in (4) is carried out for p = 5 in [211]. The notion of finite length can be refined into the notion of q/l -solvable intro- duced in [212], indicating a TQFT over R = M[y]/yl+1 such that the constant order TQFT over the ground ring M is of length q. This, clearly, defines a special case of a TQFT of length ≤ (q·l + q + l). Murakami's result [291] can be restated as saying that the Reshetikhin-Turaev theor y gives rise to a 1/1-solvable TQFT V [≤1] p with ground ring Fp (i.e. a TQFT of length 3 over Fp[y]/y2) such that V [≤1] p (M) = 1 + y 1 6 λCW L(M) (47) for any closed homology sphere M. Following Ohtsuki's work Murakami's iden- tity (with some extra renormalizations by the order of H1(M)) extends also to rational homology spheres. Let us call a theory with this pro perty a TQFT of Casson type. Recall, that the similar relation (46) for λCW L for manifolds with b1(M)≥ 1 is already contained in the information of a homological (L = 0) TQFT, and is indeed a special evaluation of the Turaev-Milnor Torsion, s ee [212]. Given the richer structure of a 1/1-solvable TQFT we will expect new in variants Ξ that are refinements of λCW L and the torsion invariants. To be more precise, note that for a pair (M, ϕ), where ϕ: π1(M)→ →Z defines a cyclic cover, any TQFT V yields an invariantV(M, ϕ) = trace(V(CΣ)) where CΣ = M- Σ: Σ → Σ and Σ ⊂ M is any surface dual to ϕ. In this way the Frohman Nicas theoriesV (j) yields the coefficients of the Alexander Polynomial, and, as shown in [212], thus also λCW L. A more refined invariant, which, roughly speaking, generali zes the Alexander module, is the Turaev-Viro module MT V (M, ϕ). It is described by Gilmer in [143]. MT V (M, ϕ) is given, up to conjugacy, by V(Σ) / ker(V(CΣ)N) (with N large enough) together with the action of V(CΣ) on it. The traces of V(CΣ) or its powers are the most obvious well defined numerical inv ariants ofMT V (M, ϕ). The dimension of the module is yet another such invariant. For a 1/1-solvable theory V the invariantV(M, ϕ) takes values in M[y]/y2 and can hence be written as V(M, ϕ) = λV ϕ(M) + y·Ξ V ϕ(M), where λV and Ξ V are now M-valued invariants. If y coincides with the half projective parameter λV does not depend on ϕ, and we expect it to be some function of λCW L. Moreover, if V descends from a 1/2-solvable TQFT with the same property also Ξ V would be independent of ϕ. For the modular TQFT over F5[y]/y2 obtained from the Reshetikhin Turaev theory this invariant has already been defined in [212], and w e may expect it to lift, similarly, to an invariant Ξ Z over Z. For p > 5 we expect, as in the case of λCW L, the next order terms in the expansions (46) of the Reshetikh in Turaev theories to be polynomial expressions in λCW L and Ξ Z.

09877 | AMR-103-0161

Problem 8.15 - (T.

O / open | AMR 问题清单汇编

(T. Kerler) [q/l -solvable and Casson TQFT’s] (1) Lift the 1/1-solvable TQFT’s of Casson type over Fp to a universal 1/1- solvable TQFT’s of Casson type over Z. (2) Describe the resulting invariant Ξ Z for 3-manifolds with b1(M)≥ 1. (3) Develop a perturbation theory for general q/l -solvable TQFT’s. (4) Relate those with the various, standard resolutions of Γ g. (5) Relate them also to the traditional finite type theory for clo sed 3-manifolds. (6) Describe the Reshetikhin-Turaev theories in this pattern. Preparations for item (1) can be found in [212] in which formu lae for the Casson invariant over Z are derived that have the same form as general TQFT formulae. Item (2) is immediate from the preceding discussion. The rem aining items are logical continuations. The category of 3-dim cobordisms Cob• between compact, oriented surfaces with one boundary component has a natural structure of a brai ded tensor cat- egory. Another, category Alg can be defined entirely algebraically in terms of generators and relations with respect to a tensor product an d a composition product. On the level of objects it has exactly one generator, say A, so that all other objects are of the form A⊗g with 1 = A⊗0. The morphisms are given by all words that can be generated by taking composition and t ensor products of elementary morphisms m: A⊗ A→ A, Δ: A→ A⊗ A, e: 1 → A, ε: A→ 1,..., that appear in the definition of a braided, ribbon Hopf algebra with integrals and a non-degenerate pairing. For example, i n [215] a surjective functorAlg-: Cob• is constructed, which, in the genus one restriction in fact an isomorphism.

09878 | AMR-103-0162

Problem 8.16 - (T.

P / partially_solved | AMR 问题清单汇编

(T. Kerler) [3-dim cobordisms from Hopf algebras] (1) Find further relations on Alg, besides the ones arising from the axiomat- ics of Hopf algebras, that would make Alg→ Cob• an isomorphism. (2) Find relations on Alg such that the maps AutAlg(A⊗g)→ Γ g~ = AutCob •(Σ g,1) are isomorphisms. (3) Relate this to obstructions, such as Steinberg and Whitehea d groups, via stratified function spaces. (4) What are the analogous algebraic structures in higher dimen sions. The first problem is easily stated, but presumably very difficu lt as it implies a faithful translation of 3-dimensional topology into an alg ebraic gadget. In this respect it is vaguely parallel to the geometrization and Poi ncar´ e conjectures. The easier problem stated in item (2) can, in theory, be attac ked head-on, given the known presentations of the mapping class groups. T he third point hints to the fact that the generators in Alg correspond to Morse-theoretically elementary cobordisms, and the relations can be interprete d, similarly, in terms of handle slides and cancellation. This is, thus, reminisce nt of the definitions of, e.g. Steinberg groups of 3-manifolds. The problem in item (4) is, again, easily stated but even in 4 dimensions lingers in almost complete to tal darkness. It is not hard to understand that higher category theory has to b e invoked and not just one “object” A suffices as a “generator”. Any partial answers may open the possibility of constructing functorial 4-manifol d invariants by “linear representation” of such structures. In [216] ETQFT’s V are defined as double functors from the double category of relative, 2-framed 1+1+1-dim cobordisms Cob∗ to the double category of linear, abelian categories over a perfect field. (The “E” sta nds for “extended to surfaces with boundaries”). Applied to a single circle, t hought of as a 0- object in Cob∗, it yields an abelian category C V = V (S1), which we call the associated circle category. The main result of [216] is a construction of a V C, for each given modular tensor category C (meaning a bounded, ribbon, braided tensor category with some additional properties) s uch that C V C =C. The construction is made for all semisimple C, and is extended, in the case of non-semisimpleC, to both to the situation of connected surfaces with boundar y as well as disconnected, closed surfaces using the previous ly mentioned notion of half-projective TQFT’s.

09879 | AMR-103-0163

Problem 8.17 - (T.

O / open | AMR 问题清单汇编

(T. Kerler) [Extended and half-projective TQFT's] (1) Describe in how far an ETQFT V with circle category C can differ from V C, thus introducing a equivalence notion that would establis h a bijective correspondence between the class of ETQFT's and the class of modular tensor categories. (2) Find an extended notion of half-projectivity that includes also surfaces that are both disconnected and have boundary. (3) Find constructions and axioms of ETQFT's that apply to more r elaxed notions of boundedness or modularity. The functorAlg→ Cob • already imposes that a circle category C V must fulfill about all axioms of a modular tensor category, and contain a H opf algebra object with properties. Given some rigidity assumption it a ctually must be the same chosen in the construction of V C. What may still differ is the choice of algebra structures of the same object in the same category, which is thus the main source of possible ambiguities. Already in [216] it is clear that there are several choices. The correct axiomatics for item (2) sho uld follow from a careful analysis of the double composition laws for surgery tangles from [216] and generalization of [210]. Item (3) is relevant to include more general notions of TQFT's as they would be of interest in the theory of finite ty pe invariants. The Reshetikhin-Turaev theory typically starts with non-s emisimple modular categoryC, typically the representation category of a non-semisimpl e quantum groups Uq(g), and then considers a canonical semisimple sub-quotient C, see [208]. Thus VC yields a semisimple TQFT. It is known that this is different from the non-semisimple TQFT VC, which in the case of a quantum group is obtained via the Hennings algorithm. TQFT's can also be generated from a rigid, monoidal category B without any braiding. One way is to take the Drinfel'd double D(B), which is then a modular category for some choice of ribbon element, and use VD(B). For semisimple B one can also extract the 6j-symbol data and follow the Turaev -Viro construction to obtain a TQFT WB.

09880 | AMR-103-0164

Problem 8.18 - (T.

P / partially_solved | AMR 问题清单汇编

(T. Kerler) [Non-semisimple vs. semisimple TQFT's, the dou - ble conjecture] (1) Clarify the difference in the content of VC andVC! Are there homological TQFT'sH such that VC is in some essential way equivalent to VC⊗H? (2) Find a construction of WB that generalizes the Turaev-Viro TQFT's to non-semisimpleB 's, similar to the way [216] generalized the Reshetikhin- Turaev construction. In the case of quantum groups and close d 3-mani- folds this should reproduce a version of the Kuperberg invar iant. (3) What is the relation between WB andVD(B)? Are they in some sense isomorphic TQFT's? For the case of Uq(sl2) there is evidence from the genus=1 case that such an H is indeed given by the Frohman-Nicas- U (1)-theory. Item (2) is rather natural as a problem. As is apparent in [236] one may expect technical challenges requiring "minimal" cell decompositions of cobordisms, as opposed to general triangulations, as well as "combings" instead of framings. The last conjecture appears also as Question 5 in [209] which was motivated by works of and discussions with D. Kazhdan and S. Gelfand in 1 994. Since it is a rather nearby conjecture from a formal point of view it may have been posed already earlier. For categories arising from subfact ors and closed mani- folds results answering this conjecture have been obtained in [204]. As outlined in [209] further, more general results in this direction sho uld yield a deeper un- derstanding of both TQFT constructions involved as well as e ntail a topological picture for the Drinfel'd double construction.

Problem 8.2 - Describe the Galois images in hg,1⊗ Zℓ.

O / open | AMR 问题清单汇编

Describe the Galois images in hg,1⊗ Zℓ. The above result was proved by analyzing the number theoretical enhancement of the Johnson homomorphism where the geometric mapping class group is replaced by the arithmetic mapping class group which is expressed as an extension 1-→ ˆMn g-→πalg 1 Mn g/Q-→Gal(Q/Q)-→1 and studied by Grothendieck, Deligne, Ihara, Drinfel'd and many number theorists. Nakamura continued to study the structure of the mapping class group from the point of view of number theory extensively (see e.g. [88][89]). On the other hand, Hain and Matsumoto recently proved remarkable results concerning this subject (see [31][32]). In view of deep theories in number theory, as well as the above explicit results, it seems to be conjectured that there should exist an embedding FreeLieZ(σ3,σ 5,⋯) ⊂ hg,1 of certain free graded Lie algebra over Z generated by certain elements σ3,σ 5,⋯, corresponding to the Soul´ e elements, into hg,1 such that the tensor product of it with Zℓ coincides with the image of Gal(Q/Q) for any prime ℓ. We expect that the above conjectured free graded Lie algebra (the motivic Lie algebra) can be realized inside hg,1 (in fact inside the commutator ideal [hg,1, hg,1]) explicitly in terms of the traces. In some sense, the elements σ2k+1 should be decomposable in higher genera. Here we omit the precise form of the expected formula which will be given in a forthcoming paper. Finally we mention the analogue of the Johnson homomorphisms for the group Aut Fn very briefly. Prior to the work of Johnson, Andreadakis [1] introduced and studied the filtration on {AutFn(k)}k which is induced from the action of Aut Fn on the lower central series of Fn. The first group Aut Fn(1) in this filtration is nothing but the group IAut n. It can be checked that an analogous procedure as in the case of the mapping class group gives rise to certain homomorphisms τk: Aut Fn(k)-→Hom(Hn,Ln(k + 1)) and the totality {τk}k of these homomorphims induces an injective homomorphism of graded Lie algebras Gr+(AutFn) = ∞⊕ k=1 AutFn(k)/AutFn(k + 1)-→Der+(Ln). (16) We refer to [49][93][98] for some of the recent works related to the above homomorphism. 368 S. Morita

Problem 9 - (Orbit closures for moduli spaces).

S / solved | AMR 问题清单汇编

(Orbit closures for moduli spaces). Determine the closures of the orbits for the GL+(2, R)-action on H(α) andQ(β). Are these closures always complex-analytic (complex-algebraic?) orbifolds? Characterize the closures geometrically. Note that by a theorem of Kontsevich any GL +(2, R)-invariant complex-analytic subvariety is represented by an affine subspace in period coordinates. Consider the subset H1(α)⊂H (α) of translation surfaces of area one. It is a real codimension one subvariety in H(α) invariant under the action of SL(2, R). In the period coordinates it is defined by a quadratic equation (the Riemann bilinear relation). It is often called a unit 15. Problems on billiards, flat surfaces and translation surfaces 253 hyperboloid. It is worth noting that it is a manifold locally modelled on a paraboloid. The invariant measure on H(α) gives a natural invariant measure on the unit hyperboloid H1(α). Similarly one can define the unit hyperboloid Q1(β). It was proved by Masur and Veech that the total measure of any H1(α),Q1(β) is finite.

Problem 9 - [Bounded Distortion Conjecture] Given a hyperbolic structure on F, associate its combinatorial invariant, namely, an…

O / open | AMR 问题清单汇编

[Bounded Distortion Conjecture] Given a hyperbolic structure on F, associate its combinatorial invariant, namely, an ideal cell decomposition of F together with the projective simplicial coordinate assigned to each edge. Take these projective simplicial coordinates as Strebel coordinates on the dual fatgraph to build a conformal structure on F. The underlying map on Teichm¨ uller space is of bounded distortion in the Teichm¨ uller metric. As posed by Ed Witten to the author in the early 1990’s, a compelling problem at that time was to find an orbifold compactification of M(F) which comes equipped with a cellular description in terms of suitably generalized fatgraphs. Calculations such as [16,19,22] and more might then be performed using matrix models derived from the combinatorics of this putative compactification. Perhaps the desired compactification was the Deligne-Mumford compactification or perhaps an- other one. The combinatorial compactification of the previous section fails to provide an orbifold but rather another stratified generalization of manifold. Guidance from Dennis Sullivan has recently led to the following solution:

背景链接：https://msp.org/gtm/2002/04/gtm-2002-04-024s.pdf

09902 | AMR-103-0172

Problem 9.8 - (Y.

P / partially_solved | AMR 问题清单汇编

(Y. Kawahigashi) There are some fusion rule algebras with 6j -symbols that do not seem to arise from quantum groups in [14] and more conjectured candidates of such examples in [160]. What are t he corresponding TQFT’s? Especially if the series conjectured in [160] does e xist, it would give a parametrized family of TQFT’s. Does a differentiation by a p arameter (af- ter a certain reparametrization) give a more interesting in variant, possibly of Vassiliev type? 9.4 Turaev-Viro-Ocneanu invariants The state-sum invariant of 3-manifolds derived from 6 j -symbols is called the Turaev-Viro-Ocneanu invariant when the set of 6 j -symbols arises from a sub- factor. There are infinitely many subfactors other than thos e derived from quantum groups or finite groups. The Turaev-Viro-Ocneanu in variants derived from such subfactors might be new invariants of 3-manifolds. (N. Sato) The Haagerup subfactor of Jones index 5+ √ 13 2 has the smallest index among finite depth subfactors with Jones index bigger t han 4 and it is expected to have some “exotic” properties from the subfacto r theoretical view- point. However, it does not seem so sensitive to classify 3-m anifolds. The Turaev-Viro-Ocneanu invariant constructed from the Haage rup subfactor can- not distinguish lens spaces L(5, 1) and L(5, 2), as well as L(7, 1) and L(7, 2). On the other hand, generalized E6 -subfactors with the group symmetries Z/3Z and Z/5Z can distinguish L(3, 1) and L(3, 2), L(5, 1) and L(5, 2), respectively.

Question 1.1 - Does the Teichm¨ uller space for Sg admit an equivariant deformation retraction onto a cocompact spine whose dimensio…

O / open | AMR 问题清单汇编

Does the Teichm¨ uller space for Sg admit an equivariant deformation retraction onto a cocompact spine whose dimension is equal to 4g- 5, the virtual cohomological dimension of Mod±(Sg)? 1if g ≥ 2 then the curvature will be negative 20. Automorphism groups of free, surface and free abelian groups 321 Further questions of a similar nature are discussed in (2.1). The issues involved in using these symmetric space analogs to prove purely group theoretic properties are illustrated in the proof of the Tits alternative, which holds for all three classes of groups. A group Γ is said to satisfy the Tits alternative if each of its subgroups either contains a non-abelian free group or else is virtually solvable. The strategy for proving this is similar in each of the three families that we are considering: inspired by Tits's original proof for linear groups (such as GL(n, Z)), one attempts to use a ping-pong argument on a suitable boundary at infinity of the symmetric space. This strategy ultimately succeeds but the details vary enormously between the three contexts, and in the case of Out(Fn) they are particularly intricate ([4, 3] versus [9]). One finds that this is often the case: analogies between the three classes of groups can be carried through to theorems, and the architecture of the expected proof is often a good guide, but at a more detailed level the techniques required vary in essential ways from one class to the next and can be of completely different orders of difficulty. Let us return to problems more directly phrased in terms of the geometry of the symmetric spaces. The symmetric space for GL(n, Z) has a left-invariant metric of non-positive curvature, the geometry of which is relevant to many areas of mathematics beyond geometric group theory. Teichm¨ uller space has two natural metrics, the Teichm¨ uller metric and the Weyl-Petersen metric, and again the study of each is a rich subject. In contrast, the metric theory of Outer space has not been developed, and in fact there is no obvious candidate for a natural metric. Thus, the following question has been left deliberately vague:

Question 1.2 - Develop a metric theory of Outer space.

O / open | AMR 问题清单汇编

Develop a metric theory of Outer space. The elements of infinite order in GL(n, Z) that are diagonalizable over C act as loxodromic isometries of X. When n = 2, these elements are the hyperbolic matrices; each fixes two points at infinity in X = H2, one a source and one a sink. The analogous type of element in Mod ±(Sg) is a pseudo-Anosov, and in Out(Fn) it is an iwip (irreducible with irreducible powers). In both cases, such elements have two fixed points at infinity (i.e. in the natural boundary of the symmetric space analog), and the action of the cyclic subgroup generated by the element exhibits the north- south dynamics familiar from the action of hyperbolic matrices on the closure of the Poincar´ e disc [62], [54]. In the case of Mod ±(Sg) this cyclic subgroup leaves invariant a unique geodesic line in Teichm¨ uller space, i.e. pseudo-Anosov's are axial like the semi-simple elements of infinite order in GL(n, Z). Initial work of Handel and Mosher [43] shows that in the case of iwips one cannot hope to have a unique axis in the same metric sense, but leaves open the possibility that there may be a reasonable notion of axis in a weaker sense. (We highlighted this problem in an earlier version of the current article.) In a more recent preprint [42] they have addressed this last point directly, defining an axis bundle associated to any iwip, cf. [63]. Nevertheless, many interesting questions remain (some of which are highlighted by Handel and Mosher). Thus we retain a modified version of our original question:

(R. Benedetti) Are torsions actually sensitive only to the (pL)-homotopy immersion classes of (pL)-knots? If one fix a C - homotopy immersion class of knots, say α, then one can define the set of finite type invariants F(α) of the C -isotopy classes contained in α. If α0 is a class of Legendrian knots, one can take α1 = f1(α0) and α2 = f2(α1); a finite type invariant for αi lifts to a finite type invariant for αi-1. So one has natural maps F(α2) f ∗ 2 →F (α1) f ∗ 1 →F (α0). It is known [130] that, under certain hypotheses on W (for instance when W is a Z-homology sphere), f ∗ 1◦ f ∗ 2 is a bijection. On the oder hand, one can Section 12.1 was written by R. Benedetti. find in [380] examples where f ∗ 1◦ f ∗ 2 is not surjective and Legendrian finite type invariants can eventually distinguish some Legendrian kno ts which are isotopic as framed knots. In fact one can realize that for these exampl es f ∗ 2 is already not surjective and that (pL)-finite type invariants can even tually distinguish some (pL)-knots which are isotopic as framed knots. The foll owing conjecture is not in contradiction with all these known results on the su bject.

Question 2 - What are the equivalence classes of braids modulo the moves • ab↔ba, and • b↔σnι(b)?

O / open | AMR 问题清单汇编

What are the equivalence classes of braids modulo the moves • ab↔ba, and • b↔σnι(b)? In other words, what happens if the Markov move b↔σ-1 n ι(b) is omitted? This question was shown in [OS03] to be equivalent to the important problem in contact geometry of classifying transversal links up to transversal isotopy. The Bennequin number of a braid b∈ Bn is e-n, where e is the sum of the exponents in a word in the generators σi representingb. The Bennequin number is invariant under the moves in Question 2. Thus it can be used to show that there are braids that are related by Markov moves, but not by the moves in Question 2. Birman and Menasco [BM] and Etnyre and Honda [EH] have independently found pairs of braids that are related by Markov moves and have the same Bennequin invariant, but are not related by the moves in Question 2. Their proofs are quite complicated, and it would be nice to have a new invariant that could distinguish their pairs of braids.

Question 2.1 - (Ends spectrum).

O / open | AMR 问题清单汇编

(Ends spectrum). What are the possibile values of ends(Modg,H) for finitely- generated subgroups H <Modg? It is well-known that the moduli space Mg has one end. The key point of the proof is that the complex of curves is connected. This proof actually gives more: any cover of Mg has one end; see, e.g., [FMa]. However, I do not see how this fact directly gives information about Question 2.1. Commensurators. Asking for two subgroups of a group to be conjugate is often too restrictive a question. A more robust notion is that of commensurability. Subgroups Γ 1, Γ2 of a group H are commensurable if there exists h ∈ H such that hΓ1h-1∩ Γ2 has finite index in both hΓ1h-1 and in Γ 2. One then wants to classify subgroups up to commensurability; this is the natural equivalence relation one studies in order to coarsify the relation of “conjugate” to ignore finite index information. The primary commensurability invariant for subgroups Γ < H is the commensurator of Γ in H, denoted Comm H (Γ), defined as: CommH (Γ):= {h∈H:hΓh-1∩ Γ has finite index in both Γ and hΓh-1} The commensurator has most commonly been studied for discrete subgroups of Lie groups. One of the most striking results about commensurators, due to Margulis, states that if Γ is an irreducible lattice in a semisimple 2 Lie group H then [Comm H (Γ): Γ] = ∞ if and only if Γ is arithmetic. In other words, it is precisely the arithmetic lattices that have infinitely many “hidden symmetries”. 2By semisimple we will always mean linear semisimple with no compact factors. 16 B. Farb

Question 2.1 - Do mapping class groups or Out(Fn) satisfy the Baum-Connes conjecture?

P / partially_solved | AMR 问题清单汇编

Do mapping class groups or Out(Fn) satisfy the Baum-Connes conjecture? Does Out(Fn) satisfy the Novikov conjecture? An approach to proving these conjectures is given by work of Rosenthal [75], generalizing results of Carlsson and Pedersen [23]. A contractible space on which a group Γ acts properly and for which the fixed point sets of finite subgroups are contractible is called an EΓ. Rosenthal's theorem says that the Baum-Connes map for Γ is split injective if there is a cocompact EΓ = E that admits a compactification X, such that (1) the Γ-action extends to X; (2) X is metrizable; (3) XG is contractible for every finite subgroup G of Γ (4) EG is dense in XG for every finite subgroup G of Γ (5) compact subsets of E become small near Y = X \E under the Γ-action: for every compact K⊂E and every neighborhood U⊂X of y∈Y, there exists a neighborhood V ⊂X of y such that γK∩V=∅ implies γK⊂U. The existence of such a space E also implies the Novikov conjecture for Γ. For Out(Fn) the spine of Outer space mentioned in the previous section is a reasonable candidate for the required EΓ, and there is a similarly defined candidate for Aut(Fn). For mapping class groups of punctured surfaces the complex of arc systems which fill up the surface is a good candidate (note that this can be identified with a subcomplex of Outer space, as in [47], section 5).

Question 2.1 - Is the Hurwitz problem for mapping class group factorizations decidable?

O / open | AMR 问题清单汇编

Is the Hurwitz problem for mapping class group factorizations decidable? Are there interesting criteria which can be used to conclude that two given factorizations are equivalent, or inequivalent, up to Hurwitz moves and global conjugation? In broader terms, the question is whether mapping class group factorizations can be used to derive non-trivial and useful invariants of Lefschetz fibrations, or even better, of the underlying symplectic 4-manifolds. At this point, it is worth mentioning two spectacular examples of such invariants which arise from geometric considerations (rather than purely from mapping class group theory). One is Sei- del's construction of a Fukaya-type A∞-category associated to a Lefschetz fibration [21], which seems to provide a computationally manageable approach to Lagrangian submanifolds and Fukaya categories in open 4-manifolds equipped with exact symplectic structures. The other is the enu- merative invariant introduced by Donaldson and Smith, which counts embedded pseudoholomor- phic curves in a symplectic 4-manifold by viewing them as sections of a "relative Hilbert scheme" associated to a Lefschetz fibration [9].

Question 2.1 - Let M = H3/Γ be a finite volume hyperbolic 3-manifold, does Γ contain a surface subgroup.

S / solved | AMR 问题清单汇编

Let M = H3/Γ be a finite volume hyperbolic 3-manifold, does Γ contain a surface subgroup. This was answered in [8] for non-compact but finite volume manifolds, and so the remaining cases of Question 2.1 are the closed manifolds, and this seems far from resolution at present. We will discuss [8] in more detail below. 2.2. Given an essential surface Σ in a finite volume hyperbolic 3-manifold M, one can at- tempt to understand the surface in terms of how the hyperbolic metric on M restricts to the surface Σ. In a non-compact finite volume hyperbolic 3-manifold there are two possibilities for the geometry of a closed essential surface Σ. Σ is either quasi-Fuchsian or it is said to contain accidental parabolics. In the latter case, as suggested by the name, these surface groups contain parabolic elements, whilst in the former case, all non-trivial elements are hyperbolic. Both these surfaces are geometrically finite. The methods of [8] only provide surfaces containing accidental parabolics, and a comment on the construction in [8] will be informative for our discussion of Γ g (see also [7]). Suppose that M = H3/Γ is a non-compact finite volume hyperbolic 3-manifold. We can assume that M is orientable on passing to a double cover if necessary, and so M is the interior of a compact 3-manifold with boundary consisting of a disjoint union of tori. Using residual finiteness of Γ there is a finite cover, ˆM of M, which has at least 3 boundary components. Standard 3-manifold topology shows that the first betti number of ˆM is at least 3, and that one can find an embedded orientable essential surface F with non-empty boundary in ˆM missing at 276 A.W. Reid least one of the boundary components of ˆM. This surface can then be used to build a finite cyclic cover of ˆM containing a closed embedded essential surface Σ of genus at least 2. Indeed, the construction is explicit, the surface Σ is constructed by taking two copies of F "tubed together" along their boundary. Σ pushes down to M to provide an essential surface in M and so the desired surface subgroup. By construction, these "tubed surfaces" contain accidental parabolic elements corresponding to the peripheral elements from ∂F. The question of existence of closed quasi-Fuchsian surfaces in M as above remains open. However recent work of Masters and Zhang [27] appears to make some progress on this. 2.3. The surface subgroups built in [8] can also be viewed as being built by repeated appli- cations of the Maskit combination theorems, a version of which is given below (see [23] and [26] Chapter VII for more details). Suppose G0,G 1,G 2< Γ with G1∩G2 =G0< Γ. If Γ acts on a set X, then we say that a pair of subsets Θ 1, Θ2⊂X is a proper interactive pair for G1,G 2 if (1) Θi=∅ for each i = 1, 2, (2) Θ1∩ Θ2 =∅, (3) G0 leaves Θ i invariant for each i = 1, 2, (4) for every φ1 ∈ G1\G0 we have φ1(Θ2)⊂ Θ1 and for every φ2 ∈ G2\G0 we have φ2(Θ1)⊂ Θ2, and (5) for i = 1, 2, there exists θi∈ Θi, such that for every φi∈Gi\G0, θi∈φi(Θi′) for i′=i. With this notation, we can state the following combination theorem.

Question 2.10 - What is the least integer δ such that Out(Fn) acts without a global fixed point on a complete CAT (0) space of dimens…

O / open | AMR 问题清单汇编

What is the least integer δ such that Out(Fn) acts without a global fixed point on a complete CAT (0) space of dimension δ? And what is the least dimension for the mapping class group Mod±(Sg)? The action of Out(Fn) on the first homology of Fn defines a map from Out(Fn) to GL(n, Z) and hence an action of Out(Fn) on the symmetric space of dimension 1 2n(n + 1)- 1. This action does not have a global fixed point and hence we obtain an upper bound on δ. On the other hand, since Out(Fn) has property F A, δ≥ 2. In fact, motivated by work of Farb on GL(n, Z), Bridson [14] has shown that using a Helly-type theorem and the structure of finite subgroups in Out(Fn), one can obtain a lower bound on δ that grows as a linear function of n. Note that a lower bound 2topological covering dimension 20. Automorphism groups of free, surface and free abelian groups 325 of 3 n- 3 on δ would imply that Outer Space did not support a complete Out(Fn)-equivariant metric of non-positive curvature. If X is a CAT(0) polyhedral complex with only finitely many isometry types of cells (e.g. a finite dimensional cube complex), then each isometry of X is either elliptic (fixes a point) or hyperbolic (has an axis of translation) [15]. If n≥ 4 then a variation on an argument of Gersten [36] shows that in any action of Out(Fn) on X, no Nielsen generator can act as a hyperbolic isometry.

Question 2.12 - Does Out(F3) have a faithful representation into GL(m, C) for some m∈ N?

O / open | AMR 问题清单汇编

Does Out(F3) have a faithful representation into GL(m, C) for some m∈ N? Note that braid groups are linear [8] but it is unknown if mapping class groups of closed surfaces are. Brendle and Hamidi-Tehrani [13] showed that the approach of Formanek and Procesi cannot be adapted directly to the mapping class groups. More precisely, they prove that the type of “poison subgroup” described above does not arise in mapping class groups. The fact that the above question remains open is an indication that Out(F3) can behave differently from Out(Fn) for n large; the existence of finite index subgroups mapping onto Z was another instance of this, and we shall see another in our discussion of automatic structures and isoperimetric inequalities.

Question 2.13 - (T.

O / open | AMR 问题清单汇编

(T. Stanford) Does Mn have an interesting complementary space in Vn? Consider, for example, the space Nn⊂ Vn of invariants v with the property that v(L) = 0 for any string link L such that π1(B3- L) is free. Is Nn nontrivial? Do Nn and Mn together span Vn? Here is some background and motivation. When considering finite-type invariants of string links, th e first ones that come to mind are the Milnor invariants. These were defined by Milno r [283] in 1954 as numbers associated to links. They are not quite invariant s of links, in the usual sense, because of some indeterminacy. They are, howev er, well-defined as invariants of string links, and this point of view was take n by Habegger and Lin [163]. After Vassiliev’s work appeared, Bar-Natan [26] and Lin [261] showed (independently) that the Milnor invariants are finit e-type invariants. Habegger and Masbaum [164] showed that on the chord diagram l evel, the Milnor invariants (including products of Milnor invariant s) are exactly the ones that vanish on Jacobi diagrams that contain internal loops, and also that the Milnor invariants are the only rational-valued finite-type invariants of string links which are also concordance invariants. String links may have local knots in the strands, and such kno ts are not detected by Milnor invariants. If a string link L has local knots, then π1(B3- L) is not free. Hence the question as to whether finite-type invariant s can show that the complement of a string link is not free. (M. Polyak) Let us review the constructions of Milnor μ -invariant in [89]. For a n-component link L = L1∪···∪Ln, regard the homotopy class of Ln as in π1 (S3- (L1∪···∪Ln-1)), and write it in terms of meridians m1,···, mn-1 of L1,···, Ln-1. Consider its Magnus expansion putting mi = 1 + Xi for non- commutative variables Xi. Then, Milnor’s μ -invariant μ i1···ik,n(L) is defined to be the coefficient of X i1···X ik in the expansion, which is an invariant under the assumption that the lower μ -invariants vanish. For example, μ 1,2 is equal to the linking number lk(L1, L2) of L1 and L2. Further, if μ i,j(L) = 0 for any i, j, then μ 12,3(L) = lk(L12, L3), where L12 denotes the link which is the intersection of Seifert surfaces of L1 and L2. In general, under the vanishing assumption of the lower μ -invariants, μ 12···n-1,n(L) = lk(L12···n-1, Ln) where L12···k (for k = 2, 3,···, n- 1) denotes the link which is the intersection of Seifert surfaces of L12···k-1 and Lk.

Question 2.3 - (Smith).

S / solved | AMR 问题清单汇编

(Smith). Is there an a priori upper bound on the length of any factorization of the boundary twist δ as a product of positive Dehn twists in Mapg,n? Equivalently: is there an upper bound (in terms of the genus only) on the number of singular fibers of a Lefschetz fibration admitting a section of square -1? (In the opposite direction, various lower bounds have been established, see e.g. [28]). Unfortunately, it is hard to quantify the amount of rotation induced by a Dehn twist on the boundary of the hyperbolic disc, so it is not clear whether the approach in [26] can shed light on this question. More generally, given an element T ∈ Map+ g,n, we can try to study factorizations of T as a product of positive Dehn twists. Geometrically, such factorizations correspond to Lefschetz fibrations over the disc (with bounded fibers), such that the monodromy along the boundary of the disc is the prescribed element T. The boundary of such a Lefschetz fibration is naturally a contact 3-manifold Y equipped with a structure of open book [10], and the total space of the fibration is a Stein filling of Y [1, 10, 15]. Hence the classification of factorizations of T in Map g,n is related to (and a subset of) the classification of Stein fillings of the contact 3-manifold Y. Some remarkable results have been obtained recently concerning the classification of symplec- tic fillings of lens spaces or links of singularities, using tools from symplectic geometry, and in particular pseudo-holomorphic curves (see e.g. [14, 18]); meanwhile, Lefschetz fibrations have 9. Mapping class group factorizations and symplectic 4-manifolds 137 been used to construct examples with infinitely many inequivalent fillings (see e.g. [20]). Hence we may ask:

Question 2.4 - Forn> 3, does Aut(Fn) have property (T)?

S / solved | AMR 问题清单汇编

Forn> 3, does Aut(Fn) have property (T)? The corresponding question for mapping class groups is also open. If Aut(Fn) were to have Property (T), then an argument of Lubotzky and Pak [64] would provide a conceptual explanation of the apparently-unreasonable effectiveness of certain algorithms in computer science, specifically the Product Replacement Algorithm of Leedham-Green et al. If a group has Property (T) then it has Serre's property F A: every action of the group on an R-tree has a fixed point. When n≥ 3, GL(n, Z) has property F A, as do Aut(Fn) and Out(Fn), and mapping class groups in genus ≥ 3 (see [28]). In contrast, McCool [67] has shown that Aut(F3) has a subgroup of finite-index with positive first betti number, i.e. a subgroup which maps onto Z. In particular this subgroup acts by translations on the line and therefore does not have property F A or (T). Since property (T) passes to finite-index subgroups, it follows that Aut(F3) does not have property (T).

Question 2.5 - Does there exist some Modg,g ≥ 2 that contains a subgroup Γ isomorphic to a cocompact (resp.

P / partially_solved | AMR 问题清单汇编

Does there exist some Modg,g ≥ 2 that contains a subgroup Γ isomorphic to a cocompact (resp. noncocompact) lattice in SO(m, 1) with m≥ 5 (resp. m≥ 4)? a cocompact lattice in SU(n, 1),n≥ 2? Must there be only finitely many conjugacy classes of any such fixed Γ in Modg? In light of example (3) above, I would like to specifically ask: can Mod g contain infinitely many isomorphism types of cocompact lattices in SO(4, 1)? Note that when Γ is the fundamental group of a (complex) algebraic variety V, then it is known that there can be at most finitely many representations ρ: Γ → Modg which have holomorphic representatives, by which we mean the unique homotopy class of maps f:V →M g with f∗ =ρ contains a holomorphic map. This result follows from repeatedly taking hyperplane sections and finally quoting the result for (complex) curves. The result for these is a theorem of Arakelov- Parshin (cf. Example 1.2 above, and §2.3 below.) For representations which do not a priori have a holomorphic representative, one might try to find a harmonic representative and then to prove a Siu-type rigidity result to obtain a holomorphic representative. One difficulty here is that it is not easy to find harmonic representatives, since (among other problems) every loop in Mg,g≥ 2 can be freely homotoped outside every compact set. For recent progress, however, see [DW] and the references contained therein.

Question 2.5 - For n > 3, does Aut(Fn) have a subgroup of finite index with positive first betti number?

P / partially_solved | AMR 问题清单汇编

For n > 3, does Aut(Fn) have a subgroup of finite index with positive first betti number? Another finite-index subgroup of Aut(F3) mapping onto Z was constructed by Alex Lubotzky, and was explained to us by Andrew Casson. Regard F3 as the fundamental group of a graph R with one vertex. The single-edge loops provide a basis {a,b,c} for F3. Consider the 2-sheeted covering ˆR → R with fundamental group ⟨a,b,c 2,cac -1,cbc -1⟩ and let G ⊂ Aut(F3) be the stabilizer of this subgroup. G acts on H1(ˆR, Q) leaving invariant the eigenspaces of the involution that generates the Galois group of the covering. The eigenspace corresponding to the eigenvalue -1 is two dimensional with basis {a-cac-1, b-cbc-1}. The action of G with respect to this basis gives an epimorphism G→ GL(2, Z). Since GL(2, Z) has a free subgroup of finite-index, we obtain a subgroup of finite index in Aut(F3) that maps onto a non-abelian free group. One can imitate the essential features of this construction with various other finite-index subgroups of Fn, thus producing subgroups of finite index in Aut(Fn) that map onto GL(m, Z). In each case one finds that m≥n- 1.

Question 2.9 - Fix a basis for Fn and let An-1⊂ Aut(Fn) be the copy of Aut(Fn-1) corresponding to the first n- 1 basis elements.

O / open | AMR 问题清单汇编

Fix a basis for Fn and let An-1⊂ Aut(Fn) be the copy of Aut(Fn-1) corre- sponding to the first n- 1 basis elements. Let φ:Aut(Fn)→G be a homomorphism of groups. If φ(An-1) is finite, must the image of φ be finite? Note that the obvious analog of this question for GL(n, Z) has a positive answer and plays a role in the foundations of algebraic K-theory. A different approach to establishing Property (T) was developed by Zuk [85]. He established a combinatorial criterion on the links of vertices in a simply connected G-complex which, if satisfied, implies that G has property (T): one must show that the smallest positive eigenvalue of the discrete Laplacian on links is sufficiently large. One might hope to apply this criterion to one of the natural complexes on which Aut(Fn) and Out(Fn) act, such as the spine of Outer space. But David Fisher has pointed out to us that the results of Izeki and Natayani [55] (alternatively, Schoen and Wang - unpublished) imply that such a strategy cannot succeed.

Question 2.9 - Is it true that, given any pseudo-Anosov φ∈ Modg, there exists n =n(φ) such that the normal closure of φn is free?

S / solved | AMR 问题清单汇编

Is it true that, given any pseudo-Anosov φ∈ Modg, there exists n =n(φ) such that the normal closure of φn is free? Gromov discovered the analogous phenomenon for elements of hyperbolic type inside nonele- mentary word-hyperbolic groups; see [Gro], Theorem 5.3.E. One should compare Question 2.8 to the Margulis Normal Subgroup Theorem (see, e.g. [Ma]), which states that if Λ is any irreducible lattice in a real, linear semisimple Lie group with no compact factors and with R-rank at least 2, then any (not necessarily finitely generated) normal subgroup of Λ is finite and central or has finite index in Λ. Indeed, we may apply this result to analyzing normal subgroups Γ of Mod g. For g≥ 2 the group Sp(2 g, Z) satisfies the hypotheses of Margulis's theorem, and so the image π(Γ) under the natural representation π: Mod g→ Sp(2g, Z) is normal, hence is finite or finite index. This proves the following. Proposition 2.10 (Maximality of Torelli). Any normal subgroup Γ of Modg containingIg is commensurable either with Modg or with Ig. Proposition 2.10 is a starting point for trying to understand Question 2.8. Note too that Mess [Me] proved that the group I 2 is an infinitely generated free group, and so it has no finitely generated normal subgroups. Thus we know that if Γ is any finitely generated normal subgroup of Mod 2, then π(Γ) has finite index in Sp(4, Z). This in turn gives strong information about Γ; see [F a3]. One can go further by considering the Malcev Lie algebra tg ofIg, computed by Hain in [Ha3]; cf.§5.4 below. The normal subgroup Γ ∩I g ofIg gives an Sp(2 g, Z)-invariant subalgebra h of tg. LetH =H1(Σg, Z). The Johnson homomorphism τ:Ig→∧ 3H/H is equivariant with respect to the action of Sp(2 g, Z), and ∧3H/H is an irreducible Sp(2 g, Z)-module. It follows that the first quotient in the lower central series of Γ ∩Ig is either trivial or is all of ∧3H/H. With more work, one can extend the result of Proposition 2.10 from Ig toKg =Ig(2); see [F a3].

Question 3.1 - (Fast word problem).

P / partially_solved | AMR 问题清单汇编

(Fast word problem). Is there a sub-quadratic time algorithm to solve the word problem in Modg? One might guess that n logn is possible here, as there is such an algorithm for certain relatively (strongly) hyperbolic groups (see [F a3]), and mapping class groups are at least weakly hyperbolic, as proven by Masur-Minsky (Theorem 1.3 of [MM1]). The conjugacy problem for Mod g is harder. The original algorithm of Hemion [He] seems to give no reasonable (even exponential) time bound. One refinement of the problem would be to prove that Mod g is biautomatic. However, even a biautomatic structure gives only an exponential time algorithm to solve the conjugacy problem. Another approach to solving the conjugacy problem is the following.

Question 3.1 - If n≥ 4 and g≥ 1, does every homomorphism from Aut(Fn) to Mod±(Sg) have finite image?

O / open | AMR 问题清单汇编

If n≥ 4 and g≥ 1, does every homomorphism from Aut(Fn) to Mod±(Sg) have finite image? By [21], one cannot obtain homomorphisms with infinite image unless Mod ±(Sg) contains the symmetric group Σ n+1. For large enough genus, you can realize any symmetric group; but the order of a finite group of symmetries is at most 84g-6, so here one needs 84 g- 6≥ (n + 1)!. 326 M. Bridson and K. Vogtmann There are no injective maps from Aut(Fn) to mapping class groups. This follows from the result of Brendle and Hamidi-Tehrani that we quoted earlier. For certain g one can construct homomorphisms Aut(F3)→Mod±(Sg) with infinite image, but we do not know the minimal such g.

Question 3.13 - (Rational growth).

O / open | AMR 问题清单汇编

(Rational growth). Does Modg have rational growth function with respect to some set of generators? with respect to every set of generators? Of course one can also ask the same question for any finitely generated subgroup of Mod g, for examplelg. Note that the existence of an automatic structure is not known to imply rationality of growth (even for one generating set); one needs in addition the property that the automatic structure consist of geodesics. Unfortunately Mosher’s automatic structure does not satisfy this stronger condition. It is natural to ask for other recursive patterns in the Cayley graph of Mod g. To be more precise, let P denote a property that elements of Mod g might or might not have. For example, P might be the property of being finite order, of lying in a fixed subgroup H <Modg, or of being pseudo-Anosov. Now let cP (r) = # {BModg (r)∩{x∈ Modg:x has P}} We now define the growth series for the property P, with respect to a fixed generating set for Γ, to be the power series fP (z) = ∞∑ i=0 cP (i)zi

09959 | AMR-109-0035

Question 3.14 - (Rational growth for properties).

O / open | AMR 问题清单汇编

(Rational growth for properties). For which properties P is the function fP is rational? Densities. For any subset S⊂ Modg, it is natural to ask how common elements of S are in Mod g. There are various ways to interpret this question, and the answer likely depends in a strong way 2. Some problems on mapping class groups and moduli space 29 on the choice of interpretation 4. One way to formalize this is via the density d(S) of S in Mod g, where d(S) = lim r→∞ #[B(r)∩S] #B(r) (9) where B(r) is the number of elements of Mod g in the ball of radius r, with respect to a fixed set of generators. While for subgroups H <Modg the number d(H) itself may depend on the choice of generating sets for H and Mod g, it is not hard to see that the (non)positivity of d(H) does not depend on the choices of generating sets. As the denominator and (typically) the numerator in (9) are exponential, one expects that d(S) = 0 for most S. Thus is it natural to replace both the numerator and denominator of (9) with their logarithms; we denote the corresponding limit as in (9) by dlog(S), and we call this the logarithmic density of S in Mod g. The following is one interpretation of a folklore conjecture.

Question 3.2 - .

P / partially_solved | AMR 问题清单汇编

. Is κ2i = 0 in H ∗(BT∞; Q)? Very little is known about the cohomology of the Torelli group past dimension 1, and as far as I know it might be possible (although hard to believe) that BT∞→ hofiber(BΓ+ ∞→B Sp(Z)+) (5) is identically zero on cohomology. The calculations in [4] show that H ∗(BΓ∞; Z) contains a wealth of torsion classes and that there are torsion classes of any order. Some of these classes might be of interest in other areas of mathematics. But the difficulty is that the description of torsion classes from [4] is indirect and complicated, and very hard to communicate to non-specialists.

09962 | AMR-109-0282

Question 3.2 - Let Γ be an irreducible lattice in a semisimple Lie group of R-rank at least 2.

S / solved | AMR 问题清单汇编

Let Γ be an irreducible lattice in a semisimple Lie group of R-rank at least 2. Does every homomorphism from Γ to Out(Fn) have finite image? This is known for non-uniform lattices (see [16]; it follows easily from the Kazdhan-Margulis finiteness theorem and the fact that solvable subgroups of Out(Fn) are virtually abelian [5]). Farb and Masur provided a positive answer to the analogous question for maps to mapping class groups [32]. The proof of their theorem was based on results of Kaimanovich and Masur [56] concerning random walks on Teichm¨ uller space. (See [54] and, for an alternative approach, [6].)

Question 3.3 - LetG~=π1(S2g)→ Γg be the injection given by Theorem 3.1.

O / open | AMR 问题清单汇编

LetG~=π1(S2g)→ Γg be the injection given by Theorem 3.1. Consider ∂∞(G) which can be canonically identified with the circle at infinity of the universal cover ˜S2g~= H2 of S2g. Does there exist a continuous G-equivariant map ∂∞(G)→ PML0(Σ)? 3.5. In the context of 3-manifold topology, given an essential surface Σ in a finite volume hyperbolic 3-manifold M, a natural question is whether there is a finite cover of M to which Σ lifts to an embedded surface. A group theoretic property that is closely related to this question is LERF, which now define. If Γ is a group, and H a subgroup of Γ, then Γ is called H-separable if for every g∈G\H, there is a subgroup K of finite index in Γ such that H⊂K but g /∈K. Γ is called LERF or subgroup separable if Γ is H-separable for all finitely generated subgroups H. This has been widely studied in the setting of low-dimensional topology (see [1] and [36] for example). Indeed, it is often the case that one does not need the full power of LERF for applications to hyperbolic manifolds, separating geometrically finite subgroups often suffices; this led to the property of GFERF, that is separable on all geometrically finite subgroups. 280 A.W. Reid Now it is known that the groups Γ g are not LERF whenever g≥ 2 since they contain F2×F2, however in analogy with the case for hyperbolic manifolds we pose (for g = 1 it is known that Γ 1 is LERF since it is virtually free):

09966 | AMR-109-0127

Question 3.4 - .

S / solved | AMR 问题清单汇编

. Is Z×BAut(F∞)+ homotopy equivalent to Ω ∞S∞? 4. The interplay between homotopy theory and the mapping class group is inspired by the study of conformal field theories, seen in [18] as representations of the surface category. The space of morphisms in Segal’s surface category is the moduli space of Riemann surfaces with parametrized boundary circles. Teichm¨ uller theory implies that this morphism space is homotopy equivalent to ⊔BΓg,b, g≥ 0,b≥ 0. Under suitable stability conditions, in our case Harer’s stability theorem, there is a close rela- tionship between the loop space of the classifying space of a category and its space of morphisms. 98 I. Madsen This was used by Tillmann to show that BΓ+ ∞ is an infinite loop space, [19], and in [13] to show that the map α of Theorem 2.1 is an infinite loop map. The situation is similar to that of algebraic K-theory, see e.g. [20]. The surface category is a special case of the cobordism category Cd that exists in all dimen- sions d≥ 1. The objects of Cd are oriented closed (d- 1)-dimensional submanifolds of R∞ and morphisms are oriented compact d-dimensional submanifolds of [0,a]× R∞, 0 <a, that meet the walls{0,a}× R∞ transversely, see [6] for details. For d = 2, Cd is homotopy equivalent to Segal’s surface category, i.e. they have homotopy equivalent classifying spaces, [13].

09972 | AMR-109-0286

Question 3.6 - Is there a map Out(Fn)→ Out(Fm) that induces an isomorphism on homology in the stable range?

O / open | AMR 问题清单汇编

Is there a map Out(Fn)→ Out(Fm) that induces an isomorphism on homology in the stable range? A number of the questions in this section and (2.2) ask whether certain quotients of Out(Fn) or Aut(Fn) are necessarily finite. The following quotients arise naturally in this setting: define Q(n,m) to be the quotient of Aut(Fn) by the normal closure of λm, where λ is the Nielsen move defined on a basis {a1,...,a n} bya1↦→a2a1. (All such Nielsen moves are conjugate in Aut(Fn), so the choice of basis does not alter the quotient.) The image of a Nielsen move in GL(n, Z) is an elementary matrix and the quotient of GL(n, Z) by the normal subgroup generated by the m-th powers of the elementary matrices is the finite group GL(n, Z/m). But Bridson and Vogtmann [21] showed that if m is sufficiently large then 20. Automorphism groups of free, surface and free abelian groups 327 Q(n,m) is infinite because it has a quotient that contains a copy of the free Burnside group B(n- 1,m). Some further information can be gained by replacing B(n- 1,m) with the quotients of Fn considered in subsection 39.3 of A.Yu. Ol’shanskii’s book [73]. But we know very little about the groups Q(n,m). For example:

Question 4.1 - Can one detect the growth of a surface or free-group homomorphism by its action on the homology of a characteristic s…

P / partially_solved | AMR 问题清单汇编

Can one detect the growth of a surface or free-group homomorphism by its action on the homology of a characteristic subgroup of finite index? Notice that one has to pass to a subgroup of finite index in order to have any hope because automorphisms of exponential growth can act trivially on homology. A. Piggott [74] has an- swered the above question for free-group automorphisms of polynomial growth, and linear-growth automorphisms of surfaces are easily dealt with, but the exponential case remains open in both settings. 328 M. Bridson and K. Vogtmann Finer questions concerning growth are addressed in the on-going work of Handel and Mosher [43]. They explore, for example, the implications of the following contrast in behaviour between surface automorphisms and free-group automorphisms: in the surface case the exponential growth rate of a pseudo-Anosov automorphism is the same as that of its inverse, but this is not the case for iwip free-group automorphisms. For mapping tori of automorphisms of free abelian groups G = Zn ⋊φ Z, the following con- ditions are equivalent (see [17]): G is automatic; G is a CAT(0) group 3; G satisfies a quadratic isoperimetric inequality. In the case of mapping tori of surface automorphisms, all mapping tori satisfy the first and last of these conditions and one understands exactly which Sg ⋊ Z are CAT(0) groups. Brady, Bridson and Reeves [12] show that there exist mapping tori of free-group automor- phismsF ⋊ Z that are not automatic, and Gersten showed that some are not CAT(0) groups [36]. On the other hand, many such groups do have these properties, and they all satisfy a quadratic isoperimetric inequality [18].

Question 4.4 - Is the conjugacy problem solvable in Out(Fn)?

P / partially_solved | AMR 问题清单汇编

Is the conjugacy problem solvable in Out(Fn)? Martin Lustig posted a detailed outline of a solution to this problem on his web page some years ago [65], but neither this proof nor any other has been accepted for publication. This problem is of central importance to the field and a clear, compelling solution would be of great interest. The conjugacy problem for mapping class groups was shown to be solvable by Hemion [52], and an effective algorithm for determining conjugacy, at least for pseudo-Anosov mapping classes, was given by Mosher [70]. The isomorphism problem for groups of the form Sg ⋊ Z can be viewed as a particular case of the solution to the isomorphism problem for fundamental groups of geometrizable 3-manifolds [76]. The solvability of the conjugacy problem for GL(n, Z) is due to Grunewald [39]

Question 4.6 - Does there exist a closed hyperbolic 4-manifold X for which no finite cover admits a symplectic structure?

O / open | AMR 问题清单汇编

Does there exist a closed hyperbolic 4-manifold X for which no finite cover admits a symplectic structure? (ie X is not virtually symplectic.) We note that it is easy to construct non-symplectic hyperbolic 4-manifolds. For example it is easy to see that the Davis manifold D (see [9]) admits no symplectic structure using the following simple parity rule (see [14] Corollary 10.1.10): Suppose that (M,ω) is a closed symplectic 4-manifold. Then 1-b1(M) + b+ 2 (M) is even. For the Davis manifold we have from [35] that b1(D) = 24 and b2(D) = 72. Since the signature of D is zero, b+ 2 (D) = 36, and so the parity condition fails. 4.3. A natural weakening of Question 4.1 is the following.

Question 4.7 - Forg,h≥ 2, does there exist a short exact sequence: 1→π1(Σg)→ Γ→π1(Σh)→ 1 for which Γ is a word hyperbolic group?

O / open | AMR 问题清单汇编

Forg,h≥ 2, does there exist a short exact sequence: 1→π1(Σg)→ Γ→π1(Σh)→ 1 for which Γ is a word hyperbolic group? Arguing as in the proof of Theorem 4.2, it follows that such an extension defines a purely pseudo-Anosov surface subgroup of Γ g. However, even in this case, little is known. We make two comments in this regard. 1. One result is that Γ cannot be the fundamental group of a closed complex hyperbolic surface. As described in [20], this follows from [25], on showing that if Γ is as decribed, then there is a non-singular holomorphic fibration X = H2 C/Γ→ Σh that induces the short exact sequence (see also [17]). 2. The following idea to construct purely pseudo-Anosov surface subgroups was described to me by Ian Agol. In [40], Thurston proves the following result (see [40] for terminology and further details). 17. Surface subgroups of mapping class groups 283

Question 4.9 - Does there exist a cocompact Fuchsian subgroup of Δ5 that misses the com- pactification locus?

O / open | AMR 问题清单汇编

Does there exist a cocompact Fuchsian subgroup of Δ5 that misses the com- pactification locus? Given such a Fuchsian subgroup F <Δ5, Agol produces a purely pseudo-Anosov subgroup in some Γ g using a branched cover construction. 4.4. One generalization of looking for surface subgroups of Γ g is to look for injections of (cocompact) lattices in Lie groups into Γ g. If the lattices are superrigid the image of such a lattice in Γ g is necessarily finite (see [12] and [43]), and so it follows (cf. Theorem 2 of [43]), that the only lattices that can admit a faithful representation (or even an infinite representation) into Γ g are lattices in SO(m, 1), m≥ 2 or SU(q, 1), q≥ 1. Indeed, since solvable subgroups of Γ g are virtually abelian [4], this observation also excludes non-cocompact lattices of SU(q, 1) for q≥ 2 from injecting. In addition, there is a simple obstruction to injecting certain of these lattices, or indeed for any group. Namely if a finitely generated group G admits an injection into Γ g, then vcd(G)≤ vcd(Γg) (see [5]). If the vcd of a group G satisfies the above inequality, then we call G admissable. The vcd’s of the groups Γ g are known to be 4 g- 5 when g≥ 2 [16]. Motivated by this discussion we pose.

09992 | AMR-109-0262

Question 5 - Is there a homological definition of representations of the Birman-Wenzl- Murakami algebra?

O / open | AMR 问题清单汇编

Is there a homological definition of representations of the Birman-Wenzl- Murakami algebra? I believe the answer to this is yes. Furthermore, the homological construction suggests a new algebra Zn, which would further generalize the Iwahori-Hecke and Birman-Wenzl-Murakami algebras. I will conclude this paper with a definition of Zn and some related open questions. I hope these might be amenable to some combinatorial computations, even without the homological motivation, which is currently unclear and unpublished. We use the notation σi1...ik as shorthand for σi1...σ ik, and ¯ σi1...ik for σ-1 i1...ik. Define the following elements of RBn. X2 = q¯σ1 + 1-q-σ1 X3 = (q2¯σ21-σ12)X2 X4 = (q3¯σ321-σ123)X3... Xn = (qn-1¯σ(n-1)...1-σ1...(n-1))Xn-1 Then Zn is the algebra RBn modulo the following relations. (q¯σ2 + 1-q-σ2)X2 = (q¯σ21-σ12)X2, (q2¯σ32-σ23)X3 = (q2¯σ321-σ123)X3, (q3¯σ432-σ234)X4 = (q3¯σ4321-σ1234)X4,... (qn-1¯σn...2-σ2...n)Xn = (qn-1¯σn...1-σ1...n)Xn. 316 S. Bigelow Note that Hn(1,-q) is the quotient of Zn by the relation X2 = 0. Also the Birman-Wenzl- Murakami algebra is the quotient of Zn by the relations X3 = 0 and σ1X2 =tX2. The following basically asks if Zn is bigger than the Birman-Wenzl-Murakami algebra.

Question 5.1 - Where precisely does the rational homology of Aut(Fn) stabilize?

O / open | AMR 问题清单汇编

Where precisely does the rational homology of Aut(Fn) stabilize? And for Out(Fn)? There are only two known non-trivial classes in the (unstable) rational homology of Out(Fn) [49, 26]. However, Morita [69] has defined an infinite series of cycles, using work of Kontsevich which identifies the homology of Out(Fn) with the cohomology of a certain infinite-dimensional Lie algebra. The first of these cycles is the generator of H4(Out(F4); Q) ~= Q, and Conant and Vogtmann showed that the second also gives a non-trivial class, in H8(Out(F6); Q) [26]. Both Morita and Conant-Vogtmann also defined more general cycles, parametrized by odd-valent graphs.

Question 5.2 - (Morita).

P / partially_solved | AMR 问题清单汇编

(Morita). Is H1(Kg, Z) finitely generated for g≥ 3? Note that Birman-Craggs-Johnson (see, e.g., [BC, Jo1]) and Morita [Mo2] have found large abelian quotients of Kg. The proof in [BF] of Theorem 5.1, suggests an approach to answering to Question 5.2. Let me briefly describe the idea. Following the the outline in [McM], we first find an action of Kg on the 2. Some problems on mapping class groups and moduli space 37 first homology of a certain abelian cover Y of Σ g; this action respects the structure of H1(Y, Z) as a module over the Galois group of the cover. The crucial piece is that we are able to reduce this to a representation ρ:Kg→ SL2(Z[t,t -1]) on the special linear group over the ring of integral laurent polynomials in one variable. This group acts on an associated Bruhat-Tits-Serre tree, and one can then analyze this action using combinatorial group theory. One might now try to answer Question 5.2 in the negative by systematically computing more elements in the image of ρ, and then analyzing more closely the action on the tree for SL 2. One potentially useful ingredient is a theorem of Grunewald-Mennike-Vaserstein [GMV] which gives free quotients of arbitrarily high rank for the group SL 2(Z[t]) and the group SL 2(K[s,t]), where K is an arbitrary finite field. Since we know for g ≥ 3 that Ig is finitely generated and Kg is not, it is natural to ask about the subgroups interpolating between these two. To be precise, consider the exact sequence (11). Corresponding to each subgroup L <∧3H/H is its pullback π-1(L). The lattice of such subgroups L can be thought of as a kind of interpolation between Ig andKg.

Question 5.3 - Do the Morita classes generate all of the rational homology of Out(Fn)?

P / partially_solved | AMR 问题清单汇编

Do the Morita classes generate all of the rational homology of Out(Fn)? The maximum dimension of a Morita class is about 4 n/3. Morita's cycles lift naturally to Aut(Fn), and again the first two are non-trivial in homology. By Galatius' result, all of these cycles must eventually disappear under the stabilization map Aut(Fn)→ Aut(Fn+1). Conant and Vogtmann show that in fact they disappear immediately after they appear, i.e. one application of the stabilization map kills them [25]. If it is true that the Morita classes generate all of the rational homology of Out(Fn) then this implies that the stable range is significantly lower than the current bound. We note that Morita has identified several conjectural relationships between his cycles and various other interesting objects, including the image of the Johnson homomorphism, the group of homology cobordism classes of homology cylinders, and the motivic Lie algebra associated to the algebraic mapping class group (see Morita's article in this volume). Since the stable rational homology of Out(Fn) is trivial, the natural maps from mapping class groups to Out(Fn) and from Out(Fn) to GL(n, Z) are of course zero. However, the unstable homology of all three classes of groups remains largely unkown and in the unstable range these maps might well be nontrivial. In particular, we note that H8(GL(6, Z); Q)~= Q [30]; this leads naturally to the question 330 M. Bridson and K. Vogtmann

Question 6.1 - Is there a set of simple Steinberg-type relations for the mapping class group?

O / open | AMR 问题清单汇编

Is there a set of simple Steinberg-type relations for the mapping class group? There is also a presentation of Aut(Fn) coming from the action of Aut(Fn) on the subcomplex of Auter space spanned by graphs of degree at most 2. This is simply-connected by [48], so Brown's method [22] can be used to write down a presentation. The vertex groups are stabilizers of marked graphs, and the edge groups are the stabilizers of pairs consisting of a marked graph and a forest in the graph. The quotient of the subcomplex modulo Aut(Fn) can be computed explicitly, and one finds that Aut(Fn) is generated by the (finite) stabilizers of seven specific marked graphs. In addition, all of the relations except two come from the natural inclusions of edge stabilizers into vertex stabilizers, i.e. either including the stabilizer of a pair (graph, forest) into the stabilizer of the graph, or into the stabilizer of the quotient of the graph modulo the forest. Thus the whole group is almost (but not quite) a pushout of these finite subgroups. In the terminology of Haefliger (see [19], II.12), the complex of groups is not simple.

10002 | AMR-109-0071

Question 6.2 - (Rigidity of the Mod g,1 action on S1).

P / partially_solved | AMR 问题清单汇编

(Rigidity of the Mod g,1 action on S1). Is any faithful action ρ: Mod g,1→ Homeo+(S1) conjugate in Homeo+(S1) to the standard action, given in (19)? What about the same question for finite index subgroups of Modg,1? Perhaps there is a vastly stronger, topological dynamics characterization of Mod g,1 inside Homeo+(S1), in the style of the Convergence Groups Conjecture (theorem of Tukia, Casson- Jungreis and Gabai), with "asymptotically source - sink" being replaced here by "asymptotically source - sink - ⋯ - source - sink", or some refinement/variation of this. Now, the group of lifts of elements of Homeo +(S1) to homeomorphisms of R gives a central extension 1→ Z→ ˜Homeo(S1)→ Homeo+(S1)→ 1 which restricts via (19) to a central extension 1→ Z→ ˜Modg,1→ Modg,1→ 1 (20) Note that Mod g,1 has torsion. Since ˜Homeo(S1)⊂ Homeo+(R) which clearly has no torsion, it follows that (20) does not split. In particular the extension (20) gives a nonvanishing class ξ∈ H 2(Modg,1, Z). Actually, it is not hard to see that ξ is simply the "euler cocycle", which assigns to any pointed map Σ h→M g the euler class of the pullback bundle of the "universal circle bundle" over Mg. The torsion in Mod g,1 and in Mod g preclude each from having a left-ordering, or acting faithfully on R. As far as we know this is the only obstruction; it disappears when one passes to appropriate finite index subgroups.

10004 | AMR-109-0072

Question 6.3 - (orderability).

O / open | AMR 问题清单汇编

(orderability). Does Modg,g ≥ 2 have some finite index subgroup which acts faithfully by homeomorphisms on S1? Does either Modg or Modg,1 have a finite index subgroup which acts faithfully by homeomorphisms on R? Note that Thurston proved that braid groups are orderable. Since Ig andIg,1 are residually torsion-free nilpotent, they are isomorphic to a subgroup of Homeo +(R); in fact one can show 8One can see this by averaging any Riemannian metric on S1 by the group action. 48 B. Farb that (20) splits when restricted to Ig,1. On the other hand, Witte [Wi] proved that no finite index subgroup of Sp(2 g, Z) acts faithfully by homoeomorphisms on S1 or on R. Non-residual finiteness of the universal central extension. The Lie group Sp(2 g, R) has infinite cyclic fundamental group. Its universal cover ˜Sp(2g, R) gives a central extension 1→ Z→ ˜Sp(2g, R)→ Sp(2g, R)→ 1 which restricts to a central extension 1→ Z→ ˜Sp(2g, Z)→ Sp(2g, Z)→ 1 (21) The cocycle ζ∈H 2(Sp(2g, Z), Z) defining the extension (21) is nontrivial and bounded; this comes from the fact that it is proportional to the Kahler class on the corresponding locally symmetric quotient (which is a K(π, 1) space). Deligne proved in [De] that ˜Sp(2g, Z) is not residually finite. Since there is an obvious surjection of exact sequences from (19) to (21), and since both central extensions give a bounded cocycle, one begins to wonder about the following.

Question I - s it possible that all nontrivial (i.e., ⁄= 1) elements of a normal subgroup of ModS are pseudo-Anosov?

S / solved | AMR 问题清单汇编

s it possible that all nontrivial (i.e.⁄= 1) elements of a normal subgroup of ModS are pseudo-Anosov? To the best of my knowledge, this question was posed independently by D. D. Long, J. D. McCarthy, and R. C. Penner in early eighties. I learned it from R. C. Penner in 1984. A moderate progress in the direction of the solution this problem is due to K. Whittlesey [Whi], who constructed examples of such subgroups in the case of spheres with 5 or more punctures and for closed surfaces of genus 2 (in the latter case the mapping class group is well-known to be 76 N. Ivanov intimately connected with the mapping class group of the sphere with 6 punctures). Unfortunately, there is, apparently, no hope to extend the method of proof to the other cases, especially to the closed surfaces of higher genus (which were the focus of all previous attempts at this problem, I suspect).

Question I - s it true that H 1(Γ) = 0 for any subgroup Γ of finite index in ModS?

P / partially_solved | AMR 问题清单汇编

s it true that H 1(Γ) = 0 for any subgroup Γ of finite index in ModS? It is well known that H 1(ModS) = 0. In his 1999 MSU Ph.D. thesis F. Taherkhani carried out some extensive computer calculation aiming at finding a subgroup of finite index with non-zero first cohomology group. For genus 2 he found several subgroups Γ with H 1(Γ⁄= 0, but in genus 3 all examined subgroups Γ turned out to have H 1(Γ) = 0. The higher genus cases apparently were well beyond the available at the time computer resources. See [T ah]. J. D. McCarthy [McC2] proved that if S is a closed surface of genus ≥ 3 and Γ is a subgroup of finite index in Mod S containing the Torelli subgroup, then the first cohomology group H 1(Γ) is trivial. His methods are based on D. Johnson results about the Torelli subgroup, the solution of the congruence subgroups problem for Sp2g(Z),g≥ 3, and the Kazhdan property (T) of Sp2g(Z), g≥ 3.

Question I - s there a constant NS, depending only on S, such that the following holds?

O / open | AMR 问题清单汇编

s there a constant NS, depending only on S, such that the following holds? Let f∈ ModS and let t =t±1 α1◦t±1 α2◦⋯◦ t±1 αn is a Dehn multi-twist. If A ={fm(αi): 1 ≤i≤n,m∈ Z} fills S (i.e. for any nontrivial circle γ there exist an α∈ A such that i(γ,α*)*= 0), then only a finite number of elements of the form tj◦f, j∈ Z are not pseudo-Anosov, and they are among NS consecutive elements of this family. 4. Fifteen problems about the mapping class groups 77 By a theorem of A. Fathi [F ath], if t is a Dehn twist, then this is true for NS = 7. A weaker version of this question is still interesting: under the same conditions, is it true that no more than NS elements among tj◦f are not pseudo-Anosov? The initial motivation for this question was that the positive answer would allow to prove the Conjecture 4 in some nontrivial cases. This motivation is now (completely?) obsolete, but I still consider this question as interesting. I believe that Fathi’s paper [F ath] is one of the deepest and the most underappreciated works in the theory of the mapping class groups. In fact, I am aware of only one application of his results: the author’s theorem [I2] to the effect that the mapping class groups have rank 1 in an appropriate sense; see [I7], Section 9.4 for a discussion. The above question may be considered as a test of our understanding of the Fathi’s ideas.

Question - Are the relations (1) - (7) the only relations which express the twist along the boundary as a product of positive tw…

P / partially_solved | AMR 问题清单汇编

Are the relations (1) - (7) the only relations which express the twist along the boundary as a product of positive twists, up to the positive equivalence in the Artin group? The motivation for this question comes from symplectic geometry. If we are given a Sym- plectic Lefschetz Fibration p: M → D of a 4-manifold M over a disk D we can describe it by its monodromy product of positive Dehn twists of a fiber over the base point p on ∂D. These are twists along vanishing cycles α1,α 2,...,α k corresponding to geometric basis of π1(D- {x1,x 2,...,x k},p), where xi’s are the critical values of the fibration. We consider the situation where the generic fiber has one boundary component and the monodromy along ∂D is equal to the twist along the boundary of the fiber. I have proven in [12] that in the case of a generic Lefschetz pencil of plane curves of any fixed degree we can choose a geometric basis of π1(CP 2-{x1,...,x k}) in such a way that the corresponding vanishing cycles αi form a bouquet. In particular each pair of curves intersects in 0 (when tangent) or 1 point. I do not know if a similar result is true for a generic pencil of curves on an algebraic surface or even more generally for any Symplectic Lefschetz Fibration without reducible fibers but it is reasonable to ask the Smith question under these restricted conditions: we assume that the twists in our product are along curves which intersect pairwise in 0 or 1 point. In particular they lie in the image of a small Artin group by a geometric homomorphism.

Question - Consider the Artin group A5 (the braid group on six strings) divided by the relation (a1a2a3a4)5 = a5a4a3a2a2 1a2a3a4a5.

O / open | AMR 问题清单汇编

Consider the Artin group A5 (the braid group on six strings) divided by the relation (a1a2a3a4)5 = a5a4a3a2a2 1a2a3a4a5. Is it true that every positive word in this group which is equal to Δ 4 4 = (a1a2a3a4)10 must have either 40 or 30 or 20 letters and in fact must be Hurwitz equivalent (see [1]) to Δ 4 4 or to Δ 2 5 = (a1a2a3a4a5)6 or to h2 = (a5a4a3a2a2 1a2a3a4a5)2? 8. Relations in the mapping class group 127 A similar question on a closed surface has an affirmative answer. Siebert and Tian proved in their recent paper (see [1]) that any genus two Symplectic Lefschetz Fibration without reducible fibers and with transitive monodromy is holomorphic. Therefore it corresponds to a monodromy factorization which is a product of conjugates of factorizations which are Hurwitz equivalent to Δ2 5 or to h2 (Δ4 4 does not have transitive monodromy). On a surface with boundary each such factor is equal to the twist along the boundary so there may be only one factor if the product is equal to a single twist, but the equivalence on the closed surface is weaker, has bigger equivalence classes so the answer on the surface with boundary may be different.

Question - Does ModS has the Kazhdan property (T)?

O / open | AMR 问题清单汇编

Does ModS has the Kazhdan property (T)? A positive answer would imply the positive answer to the previous question, but this problems seems to be much more difficult. Most of the known proofs of the property (T) for discrete groups are eventually based on the relations of these discrete groups with Lie groups and on the representation theory of Lie groups. Such an approach is not available for Mod S. New approaches to the Kazhdan Property (T) (see, for example Y. Shalom [Shal], A. ˙Zuk [Z] and the N. Bourbaki Seminar report of A. Valette [V]) hold a better promise for our problem, but, to the best of my knowledge no serious work in this direction was done. The problem remains completely open.

Question - Does there exist a set of at least three pseudo-Anosov homeomorpisms such that every pair satisfies a braid relation.

S / solved | AMR 问题清单汇编

Does there exist a set of at least three pseudo-Anosov homeomorpisms such that every pair satisfies a braid relation. The referee to this paper observed that one can easily find a pair of such pseudo-Anosov homeomorphisms satisfying braid relation of length 3. We choose elements x and y of M (S) of order 2 and 3 respectively and let g = xy and h = yx. Then g and h satisfy the relation ghg =hgh. For suitable x andy the homeomorphisms g andh are pseudo-Anosov. If S is a torus then M (S) = SL2(Z). We may require x2 =-1 and y3 = 1 and almost every choice of such matrices x and y will produce Anosov matrices g and h. For a higher genus a choice of elements x and y for which g and h are pseudo-Anosov is a little more difficult.

Question - Which Artin groups admit non-geometric embeddings into M (S)?

O / open | AMR 问题清单汇编

Which Artin groups admit non-geometric embeddings into M (S)? If we do not require the homomorphism to be geometric we do not need to restrict the question to small Artin groups. In view of the third part of lemma 2 it is easy to embed some Artin groups with some mi,j =∞ so we should restrict the question to Artin groups with finite exponents mi,j. One example is very simple. The group Bn similar to An with the first edge of the Dynkin diagram having the label 4, maps into An if we send the first generator of Bn onto the square of the first generator of An. The twists T 2 α1 and Tα2 satisfy T 2 α1Tα2T 2 α1Tα2 =Tα2T 2 α1Tα2T 2 α1. Any other Artin group of finite type maps into E8 in a similar way. The generators map onto products of powers of small number of twists. We can call such homomorphisms almost geometric. These are the only almost geometric homomorphisms which I know.

Realisation problem for the space of knots in the 3-sphere

P / partially_solved | Open Problem Garden

Problem Given a link L in S^3, let the symmetry group of L be denoted $Sym(L) = \pi_0 Diff(S^3,L)$ ie: isotopy classes of diffeomorphisms of S^3 which preserve L, where the isotopies are also required to preserve L.

Now let L be a hyperbolic link. Assume L has the further `Brunnian' property that there exists a component L_0 of L such that $L \setminus L_0$ is the unlink. Let A_L be the subgroup of $Sym(L)$ consisting of diffeomorphisms of S^3 which preserve L_0 together with its orientation, and which preserve the orientation of S^3.

There is a representation $A_L \to \pi_0 Diff(L \setminus L_0)$ given by restricting the diffeomorphism to the $L \setminus L_0$. It's known that A_L is always a cyclic group. And $\pi_0 Diff(L \setminus L_0)$ is a signed symmetric group -- the wreath product of a symmetric group with $\mathbb Z_2$.

Problem: What representations can be obtained?

Rigidity and moduli - Question 3.1

P / partially_solved | AMR 问题清单汇编

Let M be atoroidal. Is there a natural refinement of the polyhedral structure of the unit ball of the Thurston norm to a polyhedron $\mathscr{P}_\mathscr{F}$ whose faces parameterize the set of taut of foliations of M in the following sense:

- Each open face c of $\mathscr{P}_\mathscr{F}$ corresponds to a pseudo-Anosov flow X_c or equivalence classes of pseudo-Anosov flows. The taut foliations ``parameterized'' by $\mathscr{P}_\mathscr{F}$ can be isotoped to be transverse (or almost transverse) to X_c, or some sublamination is monotone equivalent into the stable or unstable singular foliation of X_c.

- Every geometric limit of taut foliations $\mathscr{F}_i$ associated to a cell c should be associated to some cell of the closure $\overline{c}$.

- There should be a natural polyhedral map from $\mathscr{P}_\mathscr{F}$ to (some polyhedral subdivision of) the unit ball of the Thurston norm.

10096 | AIM-TOPOLOGY-0104

Singular homology of cyclic graph powers

S / solved | AIM 研讨会问题汇编

Singular homology of graphs

Every simple graph can be viewed as a closure space as follows: given a graph $X = (V, E)$, we define a closure space by taking its underlying set to be V and $c(A) = \bigcup_{v \in A} c(v)$, where $c(v) = \{ w \in V \ | \ \{ v, w \} \in E\}$. For $n , k \in \mathbb{Z}$, define the graph $(\mathbb{Z}/n, c_k)$ to have the set of vertices $\mathbb{Z}/n = \{ 0, 1, \ldots, n-1\}$ and an edge between i and j whenever i and j are no more than k away.

Compute $H^{sing}_*(\mathbb{Z}/n, c_k)$. Is it isomorphic to the homomology of the clique complex of $(\mathbb{Z}/n, c_k)$?

Three substantive repairs are necessary for a literal well-posed reading.

1. A Čech closure must satisfy \(A\subseteq c(A)\). For a loopless simple graph the displayed \(c(v)\) omits \(v\). The standard intended graph closure is the **closed-neighborhood closure** \[c_G(A)=A\cup\bigcup_{v\in A}N_G(v), \] equivalently the graph relation is made reflexive. 2. “No more than \(k\) away” is taken in cyclic distance \[\delta_n(i,j)=\min\{|i-j|,n-|i-j|\}. \] Thus the underlying simple graph is the \(k\)-th power \(C_n^k\) of the \(n\)-cycle, and its reflexive relation is \(iR_kj\iff\delta_n(i,j)\le k\). 3. The notation \(H_*^{\mathrm{sing}}\) is ambiguous because several singular theories for closure spaces now exist. The paper attached to this AIM question by Milićević uses ordinary topological simplices: a singular \(q\)-simplex is a continuous map \(|\Delta^q|\to X\). This is the \(I\)- or topological-simplex singular theory computed here, with integral coefficients; no \(J\)-interval theory is silently identified with it.

The recovered problem is therefore: for \(n\ge3\), \(k\ge0\), compute the \(I\)-singular homology of the finite closure space associated with the reflexive symmetric graph \(C_n^k\), and compare it with \(H_*(\operatorname{Cl}(C_n^k);\mathbb Z)\). The degenerate cases \(n=1,2\) are recorded separately below. Negative \(k\) does not produce an extensive closure by this distance prescription.

Conjecture Let C be a Cantor set embedded in $\mathbb{R}^n$. Is there a self-homeomorphism f of $\mathbb{R}^n$ for every ϵ greater than 0 so that f moves every point by less than ϵ and $f(C)$ does not intersect C? Such an embedded Cantor set for which no such f exists (for some ϵ) is called "sticky". For what dimensions n do sticky Cantor sets exist?

The arc metric is geodesic and doubling preserves its geodesics

S / solved | AIM 研讨会问题汇编

Problem 3.7. Is the metric space $(\mathcal T(S),d_A)$ a length space? Given $X,Y\in\mathcal T(S)$, is there a geodesic Γ of $(\mathcal T(S^d),d_{\rm Th})$ connecting X and Y such that $\Gamma\subset\mathcal T(S)$?

The immediately preceding text fixes the notation:

- S is a finite-type surface with nonempty boundary; - $\mathcal T(S)$ is its reduced Teichmüller space of marked bordered hyperbolic structures; - d_A is the arc metric; - S^d is the double of S along its geodesic boundary; and - the doubling map $j:X\mapsto X^d$ is used to identify $\mathcal T(S)$ with its image in $\mathcal T(S^d)$.

With the typography restored, the question is exactly:

In the second sentence, X,Y mean their doubles after the stated identification.

The one-sided length-spectrum obstruction and a regularized asymmetric metric

P / partially_solved | AIM 研讨会问题汇编

Recovered Problem 4.2. Can one define the Thurston metric on the quasiconformal Teichmüller space \(\mathcal T_{qc}(\Gamma _0)\)?

The PDF context is essential. Section 4 begins by declaring that \(\Gamma _0\) is an infinitely generated Fuchsian group of the first kind. Immediately preceding Problem 4.2, Problem 4.1 asks whether \(\Gamma _0\) can be quasiconformally deformed so that the lengths of all simple closed curves do not increase.

Here \(X_0=\mathbb H^2/\Gamma _0\) is a complete borderless hyperbolic surface of infinite topological type, and \(\mathcal T_{qc}(\Gamma _0)\) consists of marked hyperbolic structures quasiconformally equivalent to \(X_0\). “Of the first kind” means that the limit set is the full ideal circle; it does not mean that \(X_0\) is compact. The workshop report separately mentions the *symmetrized* Thurston/length-spectrum metric, so the substantive question is the one-sided analogue, not merely the already-established symmetric metric.

Uniform critical-exponent control under quasiconformal deformation

P / partially_solved | AIM 研讨会问题汇编

Problem 4.5 (F. Guéritaud). Can we have a quasiconformal deformation of \(\Gamma _0\) which bend a variation of \(\delta(\Gamma _n)\) independent of \(n\)?

The printed source says, verbatim (apart from typographical spacing),

The string “5. The intended mathematical verb cannot be recovered with confidence. The immediately preceding text supplies the setting: \(\Gamma _0\) is an infinitely generated Fuchsian group of the first kind, and \(\Gamma _n\) is the subgroup carried by the \(n\)-ball in \(\mathbb H^2/\Gamma _0\). Problem 4.4 asks whether \(\delta(\Gamma _n)\to\delta(\Gamma _0)\).

I therefore keep the source wording visible and separate three plausible readings:

1. **uniform-bound reading:** “bend” is a typo for “bound,” and one asks for a bound on the finite change \(\delta(\Gamma_n')-\delta(\Gamma_n)\) whose constant is independent of \(n\); 2. **infinitesimal reading:** one asks for first-variation bounds for \(\frac d{dt}\delta(\Gamma_n(t))\) independent of \(n\); 3. **exact-equality reading:** one asks for a deformation for which \(\delta(\Gamma_n(t))-\delta(\Gamma_n(0))\) is literally the same function of \(t\) for every \(n\).

The first reading admits an explicit answer, and a natural asymptotic form of “independent of \(n\)” admits a positive answer along compact deformation families. The second has a conditional almost-everywhere answer. The third is much stronger and is obstructed by invariant elementary stages. Because the original intended reading remains unresolved, the result is classified as conditional rather than as a solution of the printed problem.

Unstable homotopy theory 2 - Determine the v_1 -exponents for the spheres.

S / solved | AMR 问题清单汇编

Determine the v_1 -exponents for the spheres. Recall that Cohen, Moore, and Neisendorfer showed that the p-torsion in the homotopy of S^2n+1 is all killed by p^n, but not p^n-1, for odd p. Determine the analogous v_1-exponent. I am not quite clear on the statement of this problem; I think we want to look at maps from the Moore space into X, so that the Adams map actually acts. There is probably a conjecture out there about what the exponent should be, but again I do not know it. Hopefully somebody will let me know and I can clean up this problem.

Virtual-knot problem 1 - Recognising the Kishino Knot

P / partially_solved | AMR 问题清单汇编

Recognising the Kishino Knot: There have been invented many ways to recognize the Kishino virtual knot (from the unknot): The 3-strand Jones polynomial, i.e. the Jones polynomial of the 3-strand cabling of the knot , the Ξ-polynomial, see , the quaternionic biquandle , and the surface bracket polynomial (Dye and Kauffman). In Kadokami proves the knot is non-trivial by examining the immersion class of a shadow curve in genus two. One can use the Manturov parity bracket to show that essentially the flat Kishino diagram is its own invariant, exhibiting the non-triviality of this knot. See for an exposition of this proof.

Are we done with this knot? Perhaps not. Other proofs of its non-triviality may be illuminating. The fact that the Kishino diagram is non-trivial and yet a connected sum of trivial virtual knots suggests the question: Classify when a non-trivial virtual knot can be the connected sum of two trivial virtual knots. A key point here is that the connected sum of closed virtual knots is not well defined and hence the different choices give some interesting effects. With long virtual knots, the connected sum is ordered but well-defined, and the last question is closely related to the question of classifying the different long virtual knots whose closures are equivalent to the unknot.

10232 | AMR-105-0011

Virtual-knot problem 11 - Virtualization and Unit Jones Polynomial

O / open | AMR 问题清单汇编

Virtualization and Unit Jones Polynomial: Suppose the knot K is classical and not trivial. Suppose that ${\tilde K}$ (obtained from K by virtualizing a subset of its crossings) is not trivial and has a unit Jones polynomial, $V(\tilde K)=1$. Is it possible that ${\tilde K}$ is classical (i.e. isotopic through virtual equivalence to a classical knot)?

Suppose K is a virtual knot diagram with unit Jones polynomial. Is K equivalent to a classical diagram via virtual equivalence plus crossing virtualization? (Recall that by crossing virtualization, we mean flanking a classical crossing by two virtual crossings. This operation does not affect the value of the Jones polynomial.)

Given two classical knots K and $K',$ if K can be obtained from K' by a combination of crossing virtualization and virtual Reidemeister moves, then is K classically equivalent to $K'?$

If the above two questions have affirmative answers, then the only classical knot with unit Jones polynomial is the unknot.

Virtual-knot problem 13 - Khovanov Homology

P / partially_solved | AMR 问题清单汇编

Khovanov Homology: Construct a generalization of the Khovanov complex for the case of virtual knots that will work for arbitrary virtual diagrams. Investigate the Khovanov homology constructed in . The main construction in this approach uses an orientable atom condition to give a Khovanov homology over the integers for large classes of virtual links. The import of our question, is to investigate this structure and to possibly find a way to do Khovanov homology for all virtual knots over the ring of integers. Similar questions can be raised for the presently evolving new classes of Khovanov homology theories related to other quantum invariants (cf.).

By a K-full virtual knot we mean a knot for which there exists a diagram such that the leading (the lowest, or both) term comes from the B-state. Analogously, one defines the Kho-full knot relative to the Khovanov invariant. Call such diagrams optimal diagrams. (It is easy to find knots which are neither K-full nor Kho-full.)

Classify all K-full (Kho-full) knots.

Are optimal diagrams always minimal with respect to the number of classical crossings?

Classify all diagram moves that preserve optimality.

Is it true that if a classical knot K has minimal classical diagram with n crossings then any virtual diagram of K has at least n classical crossings?

Can any virtual knot have torsion in the B-state of the Khovanov homology (the genuine leading term of some diagram)? Here we use the formulation of Khovanov homology given in .

The behaviour of the lowest and the leading term of the Kauffman bracket for virtual knots was studied in and and .

Virtual-knot problem 16 - Crossing Number

P / partially_solved | AMR 问题清单汇编

Crossing Number: One of the most important problems in knot theory is the problem of finding the minimal crossing number for a given knot. It can be estimated by means of various invariants, the simplest one, perhaps, being the Kauffman bracket estimate: $$ \mathrm{span}\langle K\rangle \leqslant 4n-4g, $$ Here span stands for the difference between the leading degree and the lowest degree non-zero terms in the Laurent polynomial defined by the Kauffman bracket, n is the crossing number, g is the atom genus for the knot K (also called the Turaev genus).

In the case $g=0$, we get the celebrated Murasugi-Kauffman-Thistlethwaite's theorem on minimality of alternating knot diagrams.

Is there is a way to prove that the atom genus g is minimal for a concrete knot diagram? Then this together with a sharp estimate for the span of the Kauffman bracket guarantees the minimality of the diagram.

The estimate $4n-4g$ is exact for adequate diagrams (after Thistlethwaite). It is exact for many diagrams which are not adequate however: there are lots of minimal diagrams where the span of the Kauffman bracket “drops down”, for example, for torus (p,q) knots for $p>q>2$.

Why is the span of the Kauffman bracket smaller than expected for such classes of knots?

One of possible explanations may be that the projection surface is wrongly chosen. For a torus knot, it is more convenient to consider it as being projected to the torus with no crossing points rather than to the plane with many crossing points. Thus the following problem arises: How do we use the Kauffman bracket, Thistlethwaite spanning tree, atoms and other invariants to get estimates for the number of crossings when projecting the knot diagram not to the plane but rather to some surfaces of higher genera?

Certainly, when applying smoothing on the plane we get the final expansion of the Kauffman bracket as a linear combination of the bracket for the unknot; we shall get expression in terms of the bracket of some “basic” torus knots, which makes the problem harder.

Can we get estimates from Thistlethwaite's spanning tree and/or from the Khovanov homology?

Which minimality theorems can be proved in this direction?

Is it possible to get an estimate for the atom genus when the atom is considered not in the neighborhood of the plane but rather in a neighborhood of the surface the knot is projected to and the thickness of the Khovanov homology does not exceed $2+g$?

Virtual-knot problem 17 - Crossing number problems

P / partially_solved | AMR 问题清单汇编

Crossing number problems: For each virtual link L, there are three crossing numbers: the minimal number C of classical crossings, the minimal number V of virtual crossings, and the minimal total number T of crossings for representatives of L. There are also a number of unknotting numbers: The classical unknotting number is the number of crossing switches needed to unknot the knot (using any diagram for the knot). The virtual unknotting number is the number of crossings one needs to convert from classical to virtual (by direct flattening) in order to unknot the knot (using any virtual diagram for the knot). Very little is known. Find out more about the virtual unknotting number.

What is the relationship between the least number of virtual crossings and the least genus in a surface representation of the virtual knot.

Is it true that $T=V+L$?

Is there any algorithm for finding V for some class of virtual knots. For T, this is partially done for two classes of links: quasialternating and some other, see . For classical links and alternating diagrams see .

Are there some (non-trivial) upper and lower bounds for $T,\,V,\,L$ coming from virtual knot polynomials (see)?

Virtual-knot problem 22 - The Rack Space

P / partially_solved | AMR 问题清单汇编

The Rack Space: The rack space was invented by Fenn, Rourke and Sanderson . The homology of the rack space has been considered by the above authors and Carter, Kamada, Saito . For low dimensions, the homology has the following interesting interpretations. Two dimensional cycles are represented by virtual link diagrams consistently colored by the rack, and three dimensional cycles by the same but with the regions also colored. See the thesis of Greene . So virtual links can give, in this way, information about classical knots! For the second homology of the dihedral rack, the results are given in Greene's thesis. We now know that for a prime p the third homology has a factor $\mathbb{Z}_p$, see .

Another line of enquiry is to look at properties of the birack space and associated homology.

Beyond problem number the cited item we list new problems that are added to this revised problem list.

P / partially_solved | AMR 问题清单汇编

Rotational virtual knot theory introduced in is virtual knot theory without the first virtual move (thus one does not allow the addition or deletion of a virtual curl). This version of virtual knot theory is significant because all quantum link invariants originally defined for classical links extend to rotational virtual knot theory. This theory has begun to be explored and deserves further exploration. We have formulated a version of the bracket polynomial for rotational virtuals that assigns variables according to the absolute value of the Whitney degree of state curves. See Figure the cited item for examples of non-trivial rotational virtual links.

The rotational bracket can be generalised in the fashion of the Arrow Polynomial. Beyond this there are all the quantum link invariants and how they behave on rotational virtuals. We are in the process of writing a new paper on rotational virtual knot theory. A natural class of invariants for rotational virtuals arises as quantum invariants associated with finite dimensional quasi-triangular Hopf algebras. This harks back to an early project that needs further articulation. In that work with Radford we articulate invariants that immediately generalize to invariants of rotational virtual knots. These invariants are defined via integrals on finite dimensional Hopf algebras and should be studied for their own sake. We would also like to know about the possibility of categorification of finite dimensional Hopf algebras and, in particular, the meaning of categorifying a right integral.

Virtual-knot problem 26 - surface arrow invariant

P / partially_solved | AMR 问题清单汇编

The arrow polynomial generalizes to a more powerful invariant of virtual knots by defining a version of it for knots in specific thickened surfaces. The arrow polynomial for a knot in a thickened surface has state variables that take into account the isotopy class of the state curve and its arrow number as well. This gives a very strong invariant of knots in thickened surfaces and it can be applied to virtual knots by using a minimal surface representative for the virtual knot. Investigating this surface arrow invariant generalizes previous work on the surface bracket polynomial .

Virtual-knot problem 29 - Khovanov homology for virtual knots and links works directly with mod-2 coefficients.

P / partially_solved | AMR 问题清单汇编

Khovanov homology for virtual knots and links works directly with mod-2 coefficients. With mod-2 coefficients there are no technical difficulties associated with the fact that a virtual state curve can resmooth to a single curve. Over the integers, this is a problem that has to be dealt with. An integral Khovanov homology for virtual knots has been constructed by Manturov . It is also the case that the work of Khovanov-Rozansky categorifiying infinitely many specializations of the Homflypt polynomial is an integral invariant for virtual knots. In principle, the Khovanov-Rozansky work solves the problem of integral Khovanov homology for virtuals, but to see this in terms of Khovanov's original definition is a very good technical problem. Solve this problem to clarify the Manturov construction.

P / partially_solved | AMR 问题清单汇编

Find a way to effectively compute the Kauffman-Radford-Hennings (KRH) invariants for three-manifolds via right integrals on finite dimensional Hopf algebras . Find a way to categorify the Kauffman-Radford-Hennings invariants for all finite dimensional quasitriangular Hopf algebras. The KRH invariants are actually invariants of rotational virtual links that are also, after normalization, invariant under the moves of the Kirby calculus. In this way, they give invariants of three manifolds and virtual three manifolds. The formulation of the KRH invariants in terms of integrals for finite dimensional Hopf algebras is very elegant, but computation is very difficult. Thus these invariants form a challenge for both virtual and classical knot theory. It is worth pointing out again, that the proper domain for all quantum link invariants is rotational virtual knot theory. Thus, this problem about the KRH invariants is a test case for the structure of quantum link invariants as a whole.

Virtual-knot problem 36 - electrical

O / open | AMR 问题清单汇编

In we show how, by translating between knots and planar graphs (the checkerboard and medial constructions) one can associate a signed graph to a classical knot and that, with a choice of nodes and an interpretation of the signs as generalized electrical conductance, the conductance between two nodes of the graph is an invariant of isotopy of the knot restricted to move in the complement of these nodes. The moves on the graphs involve replacements of pedant loops and edges, series and parallel replacements and a star-triangle exchange move. These moves can be applied to abstract (possibly non-planar) graphs. As a result we obtain a generalization of knot theory (similar in spirit but quite different from virtual knot theory) by taking the electrical equivalence classes of signed graphs. Call this theory $EG_{\pm}.$ The conductance remains an invariant of these Electric-Knots and shows that the theory is highly non-trivial. This formulation of Electric Knots gives rise to many problems. Find new invariants of Graph-Knots. Note that if we take a planar immersion of a signed graph, then the induced cyclic orders of edges at the nodes of the planar embedding give a natural way (analogous to the medial graph) to associate a virtual knot diagram to the immersion. Explore this relationship of Electric Knots and virtual knots.

P / partially_solved | AMR 问题清单汇编

It has been pointed out that the chain complex for Knot Floer Homology (categorifying the Alexander-Conway polynomial) is generated by the states described in Formal Knot Theory . These states involve an assignment of pointers to each region of the diagram (with two adjacent regions omitted) such that each pointer marks a unique crossing in the diagram. The key problem about this complex is that while the chain groups are described via knot diagram combinatorics, the differential in the complex seem to require high dimensional contact geometry. Even though there is now a combinatorial definition of Knot Floer homology via arc diagrams, this is an unsatisfactory state of affairs. The problem is to find a combinatorial definition of the differential on the complex generated by the Formal Knot Theory states.

Virtual-knot problem 4 - Virtuals and the Theory of Doodles

P / partially_solved | AMR 问题清单汇编

Virtuals and the Theory of Doodles: Compare flat theories of virtual knots with theories of doodles. A doodle is represented by a flat diagram in the plane. Reidemeister moves of type I and II are allowed but not type III. So a triple point must not be allowed. Khovanov has associated a group to doodles . Commutator identities can also be associated to a doodle. Cobordism of doodles is defined by an immersed surface without triple points. Cobordism classes represent elements of a free abelian group. There is undoubtably a rich seam of results which could be found by investigating doodles. For example there is no reason not to have virtual crossings as well as flat crossings. This would give doodles on a surface of higher genus, see .

10264 | AMR-105-0040

Virtual-knot problem 40 - Given a chord diagram D we can construct the following formal chain complex.

P / partially_solved | AMR 问题清单汇编

Given a chord diagram D we can construct the following formal chain complex. Formally speaking, this complex will look like a simplicial complex in all dimensions except zero, but one can get rid of this by using duality arguments.

In dimension -1 there is just one chain denoted by $\emptyset$. In dimension 0, the chains are in one-to-one correspondence with unoriented chords of the diagram D; in dimension 1 the chains are in one-to-one correspondence with pairs of unlinked chords, for dimension 2 we take triples of pairwise unlinked chords, etc.

The differential acts on the k-tuple, $\{a_{1},\dots, a_{k}\}$ of pairwise unlinked chords to the $(k+1)$-tuple $\{a_{1},\dots, a_{k},a_{l}\}$ obtained by the addition of a chord unlinked with all the previous ones. The sign is taken in a standard way to make the complex well-defined with integral coefficients. Such a complex is naturally defined by the intersection graph of the chord diagram.

Example. Let the chord diagram consist of $2n$ chords, where the the following pairs of chords are linked: $(1,2)$, $(3,4)$, $(5,6)$, \dots,(2n-1,2n)$. Then the corresponding simplicial complex is the $(n-1)$-sphere (the n-th join of S^{0}.

Can we get any other simplicial complexes this way other than just bouquets of spheres? An affirmative answer to this question may lead to some homological calculations which are very easy for computer implementation. This problem was motivated several years ago by an attempt to construct the spectrification of the Khovanov homology. It turns out that if some (virtual) knot in the A-state has exactly one circle then its Khovanov homology in the lowest quantum grading looks exactly as described above. Thus, this approach may be useful for understanding the Khovanov homology of chord diagrams as well as some other approaches to the Khovanov homology spectrification obtained by recent work with Lipshitz.

On the other hand, this problem is motivated the construction of graph-link theory. Indeed, every triangulated manifold admits a shallow triangulation such that together with any 1-frame of a k-simplex, it contains the whole simplex.

Considering the one-dimensional frame of such a triangulation as the non-intersection graph of some chord diagrams, we get exactly the chord diagram, whose lower term Khovanov homology looks as described above. The problem is that not every graph is an intersection graph (neither any graph is a non-intersection graph) of any chord diagram. This leads to the graph-link theory for which all possible manifolds appear in the lower degree homology theory. This leads to some lower homotopy of graph links. The next problem can be formulated as follows.

Given two diagrams of (virtual) knots or links with exactly one circle in the A-state. Which combinations of Reidemeister moves on the diagrams have to be be considered in such a way that whenever two diagrams generate equivalent knots, there exists a chain of moves from one diagram to the other with all intermediate diagrams having single-circle A-state and such that chord diagram homology (and homotopy) corresponding to those intermediate diagrams do not change under such moves?

It is worth comparing these thoughts with the recent work of Lipschitz on the spectrification of Khovanov homology. Possibly, the Bloom-Nikonov approach to Khovanov homology can be used here.

Virtual-knot problem 43 - In his wonderful paper , which firstly had the title “Knot Floer Homotopy”, Sarkar constructs a cell complex.

P / partially_solved | AMR 问题清单汇编

In his wonderful paper , which firstly had the title “Knot Floer Homotopy”, Sarkar constructs a cell complex. The homology of this complex coincides with the Floer homology. In this work the following main ingredients are used: Manolescu-Ozsváth-Sarkar-Szab\'o-Thurston approach allowing one to define Heegaard-Floer homology by using grid diagrams and shellability. Roughly speaking, if complexes look like order complexes, then they can be replaced with cell (simplicial) complexes homotopically equivalent to them.

Try to do the same things for Khovanov homology. In the initial Khovanov definition this problem seems to be very difficult, since the set of chains and states can hard be ordered. However, taking into account Bloom's construction this problem looks more optimistic.

In it was showed how one could determine non-invertibility of long virtual knots and non-commutativity of long virtual knots. This method used two type crossings: an early undercrossing and an early overcrossing. Further, for two types we have different operations, these operations are similar but not coincide (these operations are related to quandles). Regretfully, this method gives nearly nothing for classical knots. But it is universal: instead of the construction of quandle with two operations one can consider other ways of constructing knot invariants. In these ways we partition the set of crossings into two subsets, and for each subset we use an operation. Moreover, two operations are different enough to determine non-invertibility, and in the same time are similar to give an invariant structure. In the level of the Kauffman bracket polynomial this construction does not work. We get two problems.

Try to do the same for other objects than quandles, for example: nonlinear quandles, quandles with rings having non-unique decomposition of multiples.

Try to apply it on a “categorified level”: use the usual chain space for Khovanov homology and in it two different differentials but commute with each other (these differentials correspond to circle and star operations). These two different differentials could arise from usual and odd Khovanov homologies in the case when we have an identification (but maybe not canonical) between chain spaces of these complexes. It is expected that these invariants could recognize non-invertibility of knots.

Virtual-knot problem 47 - It is well known that flat virtual knots are easily algorithmically recognizable, see .

P / partially_solved | AMR 问题清单汇编

It is well known that flat virtual knots are easily algorithmically recognizable, see . The absence of a geometric approach to the definition of free knots leads to the lack of the methods for solving the following three problems.

Is it true that (any) connected sum of free knots is trivial?

Are free knots algorithmically recognizable?

Prove that free knots do not commute in the general case.

In the first case we suggest that the answer is affirmative, and the proof should be a certain modification of the analogous proof for virtual knots (see, e.g.,)

In the second case we suggest that the answer is negative. It seems to us that free knots are a very complicated object, where one can construct models for many logical constructions.

The third problem seems to be solvable by using (and, possibly, extending) standard methods in the free knot theory.

S / solved | AMR 问题清单汇编

The functorial mapping was constructed, by means of it we constructed the map from the set of virtual knots to the set of virtual knots with orientable atoms.

Can one construct an analogous map which projects the set of virtual knots to the set of classical knots? For example, one can try to find an index by using characteristic classes. Here only one condition which arises under the third Reidemeister move should hold.

Note that in the case of homologically trivial knots we can consider a two-branched covering like a projection.

Virtual-knot problem 5 - Virtual Three Manifolds

O / open | AMR 问题清单汇编

Virtual Three Manifolds: There is a theory of virtual 3-manifolds constructed as formal equivalence classes of virtual diagrams modulo generalized Kirby moves, see . From this point of view, there are two equivalences for ordinary 3-manifolds: homeomorphisms and virtual equivalence. Do these equivalences coincide? That is, given two ordinary three manifolds, presented by surgery on framed links K and L, suppose that K and L are equivalent through the virtual Kirby calculus. Does this imply that they are equivalent through the classical Kirby calculus?

What is a virtual 3-manifold?: That is, give an interpretation of these equivalence classes in the domain of geometric topology.

Construct another theory of virtual 3-manifolds by performing surgery on links in thickened surfaces $S_{g}\times \mathbb{R}$ considered up to stabilization. Will this theory coincide to that proposed by Kauffman and Dye ?

Virtual-knot problem 53 - Is there any algorithm for recognition whether two graph-links are equivalent or not?

P / partially_solved | AMR 问题清单汇编

Is there any algorithm for recognition whether two graph-links are equivalent or not? Our conjecture is “no”. The idea behind that is that graph-links are complicated enough, and possibly, they contain sufficiently many degrees of freedom to include something like Turing machines. All mathematics is roughly split into the recognizable one (low-dimensional topology, hyperbolic groups, decidability) and the non-recognizable one (topology of dimension 4 and higher, arbitrary finitely presentable groups, Turing machines etc). The usual argument for undecidability for finitely presented group allows one to construct some universal (semi)groups which includes the apparatus of the Turing machines. We think that graph-links are enough complicated to include similar things: they contain arbitrary graphs, and Reidemeister moves, in principle, could play the role of “rules for formal languages” or “group relations”. It seems unlikely that Reidemeister moves collapse graph-links to anything simple enough because of the parity considerations: there are “irreducibly odd” graph-links which are stable in the sense that every equivalent graph contains the initial graph as a subgraph.

Virtual-knot problem 6 - Welded Knots

P / partially_solved | AMR 问题清单汇编

Welded Knots: We would like to understand welded knots . It is well known that if we admit forbidden moves to the virtual link diagrams, each virtual knot can be transformed to the unknot. If we allow only one forbidden move (e.g. the upper one), then there are lots of different equivalence classes of knots. In fact the fundamental group and the quandle of the virtual diagram are invariant under the upper forbidden move. The resulting equivalence classes are called welded knots. Similarly, welded braids were studied in , and every welded knot is the closure of a welded braid. The question is to construct good invariants of welded knots and, if possible, to classify them. In a mapping is constructed from welded knots to ambient isotopy classes of embeddings of tori (ribbon tori to be exact) in four dimensional space, and it is proved that this mapping is an isomorphism from the combinatorial fundamental group (in fact the quandle) of the welded knot to the fundamental group of the complement of the corresponding torus embedding in four-space. Is this Satoh mapping faithful from equivalence classes of welded knots (links) to ambient isotopy classes of ribbon torus embeddings in four-space?

Another interesting question is the following: If a welded knot has trivial fundamental group, does this imply that the knot is trivial as a welded knot?

背景链接：https://arxiv.org/abs/1409.2823

10286 | AMR-105-0060

Virtual-knot problem 60 - Problems on Free Knot Cobordism

P / partially_solved | AMR 问题清单汇编

Problems on Free Knot Cobordism: The methods used for proving the fact that the invariant L gives an obstruction to the sliceness are not immediately generalized for obtaining lower estimates on the slice genus of free knots. Two reasons are as follows. First, when we define a parity and justified parity for double lines on $\mathcal{D}$, we chose an arbitrary curve connecting the two preimages of the point on the double curve. We assert that any two curves connecting these two preimages (and behaving correctly in neighborhoods of the ends) are homotopic. It is true in the case of cobordism of genus zero, but in the case of a surface of an arbitrary genus h it is, indeed, not true.

Thus, in order to define a parity for double lines we have to impose some restrictions on the spanning surface: we have to require that the cohomology class dual to the graph Ψ was $\mathbb{Z}_{2}$-homologically trivial. The significance of the property for even-valent graphs to be $\mathbb{Z}_{2}$-homologically trivial is closely connected with atoms (for details see Sec. the cited item and).

Another problem is that the Reeb graph of an arbitrary Morse function (not necessarily corresponding to the disc) is not necessarily a disc. Consider Fig. the cited item.

Thus, starting from a free knot K for which, we say, $L(K)=8$, we (in principle) can turn it by a Morse bifurcation into free two-component link consisting of two free knots K_{1} and K_{2}, for which $L(K_{i})=4$, and then by another Morse bifurcation we can reconstruct this trivial link into the unknot. The invariant L is not an obstruction to this, since the sum of 4 and -4 is zero.

In some cases we can overcome these two difficulties for cobordisms (of arbitrary genus).

Let $\mathcal{D}_{g}$ be a surface with boundary S^1. Obviously, the collection of double lines of $\mathcal{D}_{g}$ defines a relative $\mathbb{Z}_{2}$-homology class $\kappa\in H_1(\mathcal{D}_g,S^1;\mathbb{Z}_2)$. This homology class is an obstruction for the surface to be checkerboard-colorable; also, this is an obstruction for well-definedness of even/odd double lines.

Namely, if we look at the definition of an even/odd double line: we see that there is an ambiguity in the choice of path connecting two preimages of a generic point on the double line. For the case of a disc cobordism, the parity of double lines is well defined, because all such curves are homotopic. For $\mathcal{D}_{g}$ the unique obstruction to this well-definedness is the class κ.

We call a cobordism of genus g checkerboard (or atomic\/) if the corresponding class κ vanishes.

The next task (after detecting which 1-stratum is even and which one is odd) is to distinguish between b and b'. To this end, one should do the same for preimages of points lying on odd 1-strata, connect them by a generic curve, and count the intersection with even double lines. So, we see that the only obstruction is the relative $\mathbb{Z}_{2}$-homology class $\kappa'\in H_1(\mathcal{D}_g,S^1;\mathbb{Z}_2)$ generated by even double lines.

We say that a checkerboard cobordism is 2-atomic if κ' vanishes.

The following theorem holds.

[see] Assume for a 1-component framed 4-graph K we have $L(K)\neq 0$. Then there is no 2-atomic cobordism spanning the knot K of any genus.

In the papers the fourth author constructed a strengthening G_{m} of the group G given in the present work (in the notation our group G is G_{1}) and the invariants of free knots with values in the classes of conjugate elements from G_{m}. The idea is as follows. Even chords are further partitioned into chords of different types, it leads to more accurate definition of generators and relations in the group; these constructions are closely connected with iterated parities and the map deleting odd crossings. It seems that all invariants related to the groups G_{m} also give an obstruction to the sliceness of a knot. Moreover, in the paper the author constructed invariants of virtual knots in which the over/undercrossing structure was taken into account besides the parity of chords. We devote a separate paper to the investigation of a connection of these invariants with cobordisms.

Virtual-knot problem 7 - Long Knots and Long Flat Knots

P / partially_solved | AMR 问题清单汇编

Long Knots and Long Flat Knots: Enlarge the long knot invariant structure proposed in . Can one get new classical knot invariants from the approach in this paper? Bring together the ideas from with the biquandle construction from to obtain more powerful invariants of long knots. Long flat virtual knots can be studied via a powerful remark due to Turaev (in conversation) to the effect that one can associate to a given long flat virtual knot diagram F a descending diagram $D(F)$ (by always going over before going under in resolving the flat (non-virtual) crossings in the diagram). The long virtual knot type of $D(F)$ is an invariant of the long flat knot $F.$ This means that one can apply any other invariant I of virtual knots that one likes to $D(F)$ and $I[D(F)]$ will be an invariant of the long flat $F.$ It is quite interesting to do sample calculations of such invariants and this situation underlines the deeper problem of finding a full classification of long flat knots.

Bartholomew, Fenn, S. Kamada and N. Kamada have applied quaternion invariants to long virtual knots, see .

See also Sec. the cited item for more questions about long virtual knots and long flat virtual knots.

10319 | AIM-ANALYSIS-0070

A diagonal-trace reduction for a bilinear polynomial Carleson operator

P / partially_solved | AIM 研讨会问题汇编

With $m=\widehat K$,

\[|\partial^\alpha m(\xi)|\lesssim |\xi|^{-|\alpha|}, \qquad \xi\in\mathbb R^2\setminus\{0\}, \tag{0.13} \]

for sufficiently many multi-indices α. It then asks for a multilinear analogue of the Stein--Wainger polynomial Carleson theorem, giving as its example

\[\left\|\sup_{\lambda\in\mathbb R} \left|\int_{\mathbb R^2}f(x-t)g(x-s)K(t,s) e^{i\lambda s^2t^2}\,dt\,ds\right|\right\|_{L^2_x} \lesssim \|f\|_{L^4}\|g\|_{L^4}. \tag{0.14} \]

Thus the phase is unambiguously the mixed quartic monomial s^2t^2, not a quadratic or a sum of one-variable monomials.

The PDF next cites Li and Muscalu's translated-multiplier theorem. Comparison with Li--Muscalu's primary statement recovers the intended symbol as

\[m(\xi-N)=m(\xi_1-N_1,\xi_2-N_2), \]

and the corresponding bilinear maximal operator is

\[C_m(f_1,f_2)(x)=\sup_{N\in\mathbb R^2} \left|\int_{\mathbb R^2}m(\xi-N)\widehat f_1(\xi_1) \widehat f_2(\xi_2)e^{2\pi ix(\xi_1+\xi_2)}\,d\xi\right|. \]

That theorem concerns linear translations of a multiplier in frequency; it does not contain the physical-variable quartic phase in (0.14).

For a genuinely singular K, (0.14) must be interpreted by principal values or compatible smooth truncations. The workshop question does not specify a truncation convention. Below, K is given the usual translation-invariant Calderón--Zygmund realization associated with the Mikhlin symbol m. If one does not assume enough regularity in (0.13) to obtain a standard Hölder Calderón--Zygmund kernel, the all-scale Sobolev theorem below should instead be read under the explicit ambient maximal hypothesis in Theorem 5.1.

A formulation audit and ball-calibration obstruction for space-form quermassintegral problems

O / open | AIM 研讨会问题汇编

Isoperimetric type problems for quermassintegrals in hyperbolic or spherical space.

It is item 1.5 in the “Inequalities” section of the 2019 AIM workshop *Symmetry and convexity in geometric inequalities*. The record contains no remarks or literature field.

This sentence names a research direction, not a proposition with a truth value: it specifies neither dimension, normalization of quermassintegrals, pair of indices, admissible sets, convexity condition, inequality direction, nor equality case. I therefore classify this record as `context_only`, not as a solved or open theorem.

A defensible modern decomposition is:

1. the classical volume/surface-area isoperimetric inequality in a space form; 2. pairwise Alexandrov--Fenchel inequalities between genuine quermassintegrals, with equality at geodesic balls; 3. analogous inequalities for raw curvature integrals; 4. variants under convexity, horospherical convexity, star-shapedness, or curvature-cone hypotheses; 5. stability estimates measuring distance from a ball by the inequality deficit.

These are different problems. Results for one class or normalization must not be reported as resolving all the others.

A half-measure Fourier frame with no two-Riesz partition

P / partially_solved | AIM 研讨会问题汇编

Does there exist a measurable \(E\subset\mathbb T=\mathbb R/\mathbb Z\), with \(|E|=1/2\), such that for every partition \(\mathbb Z=A\sqcup B\), at least one of \(\mathcal E_E(A)\) and \(\mathcal E_E(B)\) fails to be a Riesz sequence in \(L^2(E)\)?

It appears under Darrin Speegle's name.

The preceding lines say that \(E\subset[0,1]\) is measurable and that the displayed family is an exponential frame. The standard notation in Speegle's work and the surrounding sentence recover the intended family unambiguously as

\[\mathcal E_E(\mathbb Z) =\{e_n\chi_E:n\in\mathbb Z\}, \qquad e_n(x)=e^{2\pi i n x}, \]

viewed either in \(L^2(\mathbb T)\) with support in \(E\), or canonically in \(L^2(E)\). Thus the question is:

This report answers **yes**. The set can be chosen compact and contained strictly inside one representative interval \([0,1)\).

10336 | AIM-ANALYSIS-0064

A hybrid spectral-complexity reduction for the maximal directional Hilbert transform

P / partially_solved | AIM 研讨会问题汇编

2 of the AIM PDF. The authoritative display is

\[\left\|\sup_{j\in\{1,2,\ldots,N\}}|H_{v_j}f|\right\|_{L^{2,\infty}(\mathbb R^2)} \lesssim \sqrt{\log N}\,\|f\|_2, \tag{0.4} \]

for a collection \(\{v_j\in S^1:1\leq j\leq N\}\), where the PDF prints

\[H_{v_j}f(x):=\int_{\mathbb R}f(x-tv_j)\,\frac{dt}{t}. \tag{0.5} \]

Three conventions or repairs are necessary.

1. The singular integral in (0.5) must be interpreted as a Cauchy principal value. This is the convention in all cited primary literature and is required even for Schwartz functions. 2. The weak norm used here is \[\|g\|_{2,\infty}^{*}:=\sup_{\lambda>0}\lambda |\{x:|g(x)|>\lambda\}|^{1/2}. \] The superscript \({}^{*}\) is suppressed below when no ambiguity arises. Thus (0.4) is equivalent, up to squaring its constant, to \[|\{H_Vf>\lambda\}|\lesssim \frac{\log N}{\lambda^2}\|f\|_2^2, \qquad H_Vf:=\sup_{v\in V}|H_vf|. \] 3. The literal statement is false for \(N=1\), since \(\sqrt{\log 1}=0\) but \(H_v\) is nonzero. The intended asymptotic statement is for \(N\geq2\), or uniformly with \(\sqrt{\log(1+N)}\). Repetitions and antipodal directions do not change the operator, so the most intrinsic parameter is the number \(M\) of distinct projective directions \([v]=\{v,-v\}\), and the clean formulation uses \(\sqrt{\log(1+M)}\).

The symbol \(\lesssim\) in the question means a constant independent of \(N\), the directions, and \(f\) (after fixing the normalization of the Hilbert transform).

10337 | AIM-SPECIAL_FUNCTIONS-0007

A Lam--Kato bridge for the geometric and graded meanings of k-Schur functions

P / partially_solved | AIM 研讨会问题汇编

“(7) Elucidate the representation-theoretical significance of the \(k\)-Schur functions. The answer may involve either representation theory of symmetric groups or representation theory of Lie algebras.”

The exact AIM record is:

It is Problem 7 in the 2005 AIM workshop list on Generalized Kostka Polynomials, <https://aimath.org/WWN/kostka/prob2.pdf>. The surrounding workshop notes use the one-parameter recursive \(k\)-Schur functions \(s_\lambda^{(k)}[X;t]\). The problem is deliberately open-ended: it asks for a representation-theoretic model, not for a yes/no assertion.

There are now two answers which must not be conflated:

1. the parameter-forgotten specialization \(s_\lambda^{(k)}[X;1]\) represents an affine-Grassmannian homology Schubert class; 2. the full graded modern \(k\)-Schur function is the graded character of a finite-dimensional module for a current algebra, equivalently for a skew group algebra containing \(\mathbb C\mathfrak S_m\).

The first answer is geometric and was published by Lam. The second is the main subject of Kato's current arXiv preprint. The parameter is called \(t\) in the older literature and \(q\) in Kato's convention. Below it is denoted by \(u\) whenever the name is immaterial.

A mixed local approximation obstruction for the nuclear UCT problem

P / partially_solved | AIM 研讨会问题汇编

UCT problem. Does every **separable nuclear** C\(^*\)-algebra satisfy the Rosenberg--Schochet UCT?

The source omits the word “separable.” In the Rosenberg--Schochet framework, and in modern statements of the UCT problem, the intended question is:

The separability qualification is material: classical Kasparov \(KK\)-theory and the bootstrap category used here have separable C\(^*\)-algebras as objects. There are nonseparable variants of bivariant theory, but the literal all-cardinalities reading would require an additional choice not made in the AIM record. This report treats the standard separable problem.

For separable C\(^*\)-algebras \(A,D\), let \[\gamma_{A,D}:KK_*(A,D)\longrightarrow \operatorname{Hom}_{\mathbb Z}^{*}(K_*(A),K_*(D)) \] be induced by Kasparov product. The algebra \(A\) satisfies the UCT if, for every separable \(D\), there is a natural short exact sequence of \(\mathbb Z/2\)-graded groups \[0\longrightarrow \operatorname{Ext}_{\mathbb Z}^{1,*}(K_*(A),K_{*+1}(D)) \longrightarrow KK_*(A,D) \xrightarrow{\gamma_{A,D}} \operatorname{Hom}_{\mathbb Z}^{*}(K_*(A),K_*(D)) \longrightarrow0. \tag{1} \] The shift records that the \(\operatorname{Ext}^1\) map has odd degree. The sequence splits, but not naturally. For separable nuclear \(A\), Rosenberg--Schochet theory gives the equivalent conditions:

1. (1) holds for every separable \(D\); 2. \(A\) is \(KK\)-equivalent to a commutative C\(^*\)-algebra; 3. \(A\) lies in the Large Bootstrap Class \(\mathcal N\), the smallest class of separable nuclear algebras containing \(\mathbb C\), closed under \(KK\)-equivalence and the two-out-of-three property for semisplit extensions.

The preceding AIM record, Problem 4.2, is the **Small Bootstrap Problem**. In Blackadar’s terminology, the Small Bootstrap Class \(\mathcal B\) is generated constructively from finite-dimensional and separable commutative algebras using two-out-of-three for extensions, finite tensor products, inductive limits, stable isomorphism, and crossed products by \(\mathbb Z\). The Large Bootstrap/UCT Class \(\mathcal N\) additionally closes from \(\mathbb C\) under \(KK\)-equivalence. One has \[\mathcal B\subseteq\mathcal N. \] Thus a positive answer to Problem 4.2 implies a positive answer to Problem 4.3, but the UCT problem is potentially strictly weaker. The two AIM records should not be collapsed into one question.

10349 | AIM-ANALYSIS-0143

A paired-tail reduction and coefficientwise positivity through n=5

P / partially_solved | AIM 研讨会问题汇编

Let \[Q_n^{(\alpha,\beta)}(x):=\sum_{k=0}^n\binom nk f_kf_{n-k} \left((x+\alpha)_k(x+\beta)_{n-k}-(x+\alpha+\beta)_k(x)_{n-k}\right), \] where \(\alpha,\beta>0\), \(f_k^2\ge f_{k-1}f_{k+1}\), and \((x)_k=x(x+1)\cdots(x+k-1)\). Then the Maclaurin coefficients of \(Q^{(\alpha,\beta)}\) are nonnegative.

Karp, and remarks that the case \(\alpha=\beta=1\) was proved in arXiv:1203.1482.

The cited paper removes several ambiguities in the abbreviated AIM text:

* \(n\) is a nonnegative integer; the substantive conjecture is for \(n\ge3\), while the determinant generating series begins at \(n=2\). * \((x)_0=1\). * The sequence is intended to be **nonnegative and log-concave without internal zeros**. The local inequalities alone are not the intended definition. * The final \(Q^{(\alpha,\beta)}\) on the AIM page means \(Q_n^{(\alpha,\beta)}\); omission of \(n\) is a typographical abbreviation, as is clear from the defining equation and from Karp’s equation (3). * Karp’s original Conjecture 1 assumes strict log-concavity and asks for positive coefficients for \(n\ge3\). The AIM statement is its natural weak/nonnegative version.

This report proves that weak version for every \(\alpha,\beta>0\) and every \(0\le n\le5\), gives a general tail-kernel reduction, and shows exactly why nonnegativity and the no-internal-zero condition cannot be omitted.

A parity reduction and gradient-cone test for directional hot spots

P / partially_solved | AIM 研讨会问题汇编

For every nonzero real eigenfunction u in the first positive Neumann eigenspace $E_1(\Omega)$, does there exist a nonzero vector $e=e(u)$ such that $e\cdot\nabla u(x)>0$ for every $x\in\Omega$?

The phrase "the eigenfunction" is ambiguous when the first positive eigenvalue is multiple. This matters for the disk and the square. The intended source, Jerison--Nadirashvili's Conjecture 8.4, says **any** Neumann eigenfunction with the lowest nonzero eigenvalue and lets the direction depend on that eigenfunction. Accordingly, the recovered formulation used here is:

Multiplying e by a positive scalar changes nothing, so e may be required to be a unit vector. Replacing u by $-u$ replaces a good direction by $-e$. The inequality is only in the open domain. It generally degenerates at boundary support points because of the Neumann condition, so it must not be silently strengthened to $\overline\Omega$.

For a nonsmooth convex domain, the Neumann problem is understood weakly. Eigenfunctions are analytic in the interior, which is enough to interpret the displayed inequality there. The new parity theorem below is deliberately stated for a smooth boundary because its proof differentiates the boundary condition.

10357 | AIM-ANALYSIS-0072

A resonant obstruction to the displayed physical-space maximal estimate

S / solved | AIM 研讨会问题汇编

With the Fourier convention

\[\widehat f(\xi)=\int_{\mathbb R^n}f(x)e^{-2\pi i x\cdot\xi}\,dx, \]

Question 13 (Carbery) first records the higher-dimensional spherical Carleson problem

\[\left\|\sup_R\left|\int_{|\xi|\leq R} \widehat f(\xi)e^{2\pi i x\cdot\xi}\,d\xi\right|\right\|_2 \lesssim \|f\|_2. \tag{0.18} \]

It then asks, literally,

\[\left\|\sup_R\left|f*\left(\frac{e^{i|x|}}{|x|^{(n+1)/2}}\, \chi_{\{|x|\leq R\}}\right)\right|\right\|_2 \lesssim \|f\|_2? \tag{0.19} \]

The context makes the supremum an unbounded supremum over positive radii. In particular, neither a square on the phase nor a conjugate oscillatory branch is present in (0.19). This was also checked directly in the decompressed PDF content stream. The PDF cites Carbery--Gorges--Marletta--Thiele, although its bibliography misspells Marletta as “Marietta.”

For every finite \(R\), the kernel in (0.19) is locally integrable exactly when \(n\geq2\). Thus the literal formula needs an additional prescription in dimension one; all results below concern \(n\geq2\), the range relevant to the higher-dimensional question.

10359 | AIM-SEVERAL_COMPLEX_VARIABLES-0001

A scale obstruction to the coefficient-one formulation

S / solved | AIM 研讨会问题汇编

Let \(\Omega\subset\mathbb C^n\) be pseudoconvex and contain \(0\), let \(H\) be a hyperplane through \(0\), and let \(\phi\in L^1_{\mathrm{loc}}(\Omega)\). Assuming \[i\partial\bar\partial\phi\geq -C\,i\partial\bar\partial\log B_\Omega(z,z), \] how large may \(C\) be while every holomorphic \(f\) on \(H\cap\Omega\) of finite weighted \(L^2\)-norm has an extension \(F\in\mathcal O(\Omega)\) satisfying the coefficient-one estimate \[\int_\Omega |F|^2e^{-\phi}\,dV_n \leq \int_{H\cap\Omega}|f|^2e^{-\phi}\,dV_{n-1}? \tag{1} \] It also asks whether \(C\) can be universal. The source says that \(C=0\) is Ohsawa--Takegoshi and that, for strictly pseudoconvex \(\Omega\), ``\(C\geq 1/(n+1)\) works.''

There are two problems with this literal wording.

1. The coefficient \(1\) in (1) has units of length squared and is not preserved by dilation. Classical Euclidean Ohsawa--Takegoshi extension has a constant depending on a transverse size of the domain (in a common elementary statement, on its diameter), unless a transverse defining function and its normalization are included. 2. Since \(\omega_{B,\Omega}:=i\partial\bar\partial\log B_\Omega(z,z)\geq0\), the class of allowed weights grows as \(C\) grows. Thus a theorem at \(C_0\) implies the same theorem for \(0\leq C\leq C_0\), not for \(C\geq C_0\). The bullet can coherently mean either ``\(C=1/(n+1)\) works'' or ``the supremum of admissible \(C\)'s is at least \(1/(n+1)\).''

10361 | AIM-SEVERAL_COMPLEX_VARIABLES-0002

A sign-corrected, defining-function-sensitive reduction of the worm Dirichlet problem

P / partially_solved | AIM 研讨会问题汇编

Fix a defining function \(\rho<0\) for which \(\Phi_\rho=-\log(-\rho)\) is strictly plurisubharmonic. Let \(\omega_\rho=i\partial\bar\partial\Phi_\rho\) and let \(\Delta_\rho\) be its Laplace--Beltrami operator. For \(f\in C^\infty(\partial\mathcal W)\), determine the boundary regularity of the solution of \(\Delta_\rho u=0\) in \(\mathcal W\), \(u=f\) on \(\partial\mathcal W\), after fixing or normalizing the defining function.

The supplied AIM record asks for boundary regularity on the smooth Diederich--Fornæss worm \(\mathcal W\subset\mathbb C^2\) for the Laplace--Beltrami operator associated with the displayed form \[i\partial\bar\partial\log(-\rho), \] where \(\rho<0\) in \(\mathcal W\), and prints the boundary condition as `\(\nu=f\)`.

There are two formulation problems.

1. Since the problem explicitly calls itself Dirichlet, `\(\nu=f\)` is reconstructed as \[u=f\quad\hbox{on }\partial\mathcal W. \] This is a semantic reconstruction of an apparent extraction/OCR error. The current AIM source URL was unavailable during this run, so it was not independently verified against the original rendered page. 2. With the standard positivity convention for a Kähler form and \(\rho<0\), the displayed potential has the wrong sign. Indeed, \[i\partial\bar\partial\log(-\rho) =-i\partial\bar\partial[-\log(-\rho)]. \] Thus whenever the usual logarithmic metric is positive, the displayed form is negative.

The mathematically coherent version studied here is therefore:

The qualification on \(\rho\) is essential: an arbitrary defining function need not make \(-\log(-\rho)\) strictly plurisubharmonic.

来源字段：http://aimpl.org/hyperbolicpoly/2/

10363 | AIM-ANALYSIS-0012

A spherical log gas on a smooth loop

P / partially_solved | AIM 研讨会问题汇编

The AIM record is Problem 2.7 from the 2024 workshop *Riemann-Hilbert problems, Toeplitz matrices, and applications*. Its exact stored text is

\[Z_N=\int_{\Gamma} \cdots \int_{\Gamma} \prod_{i \leq j < k \leq N}|z_k-z_j|^{2\beta} \prod_{j=1}^N\left(\frac{1}{1+|z_j|^2}\right)^{(N-1)\beta+1} d|z_1|\cdots d|z_N|, \]

Two conservative repairs are necessary before the displayed quantity defines the customary symmetric log gas.

1. The unused index \(i\) in \(\prod_{i\leq j<k\leq N}\) would repeat the pair \((j,k)\) exactly \(j\) times and destroy permutation symmetry. We therefore read it as the standard Vandermonde product \(\prod_{1\leq j<k\leq N}\). 2. We read \(d|z|\) as Euclidean arclength \(|dz|\). Read literally as the differential of the radial coordinate, it vanishes on a circle centered at the origin and is not a positive measure on a general loop.

The reconstructed problem studied below is consequently

\[\boxed{ Z_N(\Gamma,\beta)=\int_{\Gamma^N} \prod_{1\leq j<k\leq N}|z_j-z_k|^{2\beta} \prod_{j=1}^N(1+|z_j|^2)^{-[(N-1)\beta+1]}|dz_j|.} \tag{1.1} \]

Here \(\Gamma\) is assumed to be an embedded \(C^2\) loop, and the particles are labelled: there is no factor \(1/N!\). The main large-\(N\) result is for fixed \(\beta>0\). For \(\beta=0\) the integral is elementary. For a fixed negative real \(\beta\), the integral ceases to exist once \(N\) is large enough, so no unrenormalized large-\(N\) question remains.

10368 | AIM-ANALYSIS-0031

A target-specific q_Omega criterion for strict disk comparison

P / partially_solved | AIM 研讨会问题汇编

Prove or disprove that among all planar domains of a given area, the disk is the unique minimizer for the smallest positive eigenvalue \(\nu _1(\Omega)\) of the Dirac problem with infinite mass boundary conditions

\[\begin{cases} -\mathsf i(\partial _1v-\mathsf i\partial _2v)=\nu u&\text{in }\Omega,\\ -\mathsf i(\partial _1u+\mathsf i\partial _2u)=\nu v&\text{in }\Omega,\\ \mathsf i(n_1+\mathsf i n_2)u=v&\text{on }\partial\Omega, \end{cases} \] where \(n=(n_1,n_2)^\top\) is the outer unit normal.

The phrase “all planar domains” needs a regularity convention. The 2021 formulation used bounded, simply connected \(C^\infty\) domains. The current results used below establish self-adjointness, discreteness, and the required variational characterization for bounded planar domains with \(C^2\) boundary, without a simple-connectivity hypothesis. Accordingly, the rigorous partial theorem in this report is for bounded connected \(C^2\) domains. No claim is made for arbitrary rough domains, where even the operator realization in the displayed form requires care.

Writing the complex normal as \(\mathbf n=n_1+\mathsf i n_2\), the boundary condition is \(v=\mathsf i\mathbf n u\). This is exactly the massless infinite-mass member \((\theta,m)=(0,0)\) of the quantum-dot Dirac family used in the 2026 literature: its convention \(\overline{\mathbf n}v=\mathsf i\vartheta(0)u\), with \(\vartheta(0)=1\), becomes the same condition after multiplication by \(\mathbf n\).

10369 | AIM-ANALYSIS-0142

A three-nonzero-root theorem for Fisk's 3x3 Toeplitz-minor transform

P / partially_solved | AIM 研讨会问题汇编

It asks the following. Given

\[p(x)=\sum_{k=0}^{n}a_kx^k\in\mathcal L\!-\!\mathcal P^+, \]

\[\mathcal T_3p(x):=\sum_{k=0}^{n}D_k^{(3)}x^k\in\mathcal L\!-\!\mathcal P^+, \qquad D_k^{(3)}:=\det[a_{k+j-i}]_{i,j=0}^{2}? \tag{1} \]

Here the determinant is

\[\det\!\begin{pmatrix} a_k&a_{k+1}&a_{k+2}\\ a_{k-1}&a_k&a_{k+1}\\ a_{k-2}&a_{k-1}&a_k \end{pmatrix}. \]

The AIM record only declares \(a_{-1}=a_{n+1}=0\) immediately before its \(2\times2\) formula. The \(3\times3\) display also uses \(a_{-2}\) and \(a_{n+2}\), so it is not literally defined without an added convention. Fisk's paper and Yoshida's formulation use the natural zero extension

\[a_j=0\quad\text{for every }j\notin\{0,\ldots,n\}. \tag{2} \]

All results below use (2). For a nonzero finite polynomial, membership in \(\mathcal L\!-\!\mathcal P^+\) is equivalent to having nonnegative coefficients and only real, nonpositive zeros. If the zero polynomial is admitted, it maps to zero and is a separate trivial boundary case.

All-coupling reverse Robin inequality for tangential domains

P / partially_solved | AIM 研讨会问题汇编

“...with a boundary parameter $\alpha0$ centred at the origin.”

This record is item 1.2, “Bareket's conjecture,” in the AIM list from the workshop *Shape optimization with surface interactions*.

The enumerated conjecture that follows is intact.

1. If $d=2$, $\alpha<0$, and Ω is bounded and simply connected, then the disk B_R with $|B_R|=|\Omega|$ satisfies \[\lambda_1(\Omega,\alpha)\leq \lambda_1(B_R,\alpha). \] 2. If $d\geq3$, $\alpha<0$, and Ω is bounded and convex, then the ball B_R with $|B_R|=|\Omega|$ satisfies the same inequality.

Here and below the sign convention is \[-\Delta u=\lambda u\quad\hbox{in }\Omega, \qquad \partial_\nu u+\alpha u=0\quad\hbox{on }\partial\Omega, \qquad \alpha<0. \] Only the damaged prose before the displayed list has been reconstructed. No mathematical symbol missing from the two-part conjecture is needed below.

10389 | AIM-ANALYSIS-0020

All-coupling Robin bound states for compact graph deformations in dimensions two and three

P / partially_solved | AIM 研讨会问题汇编

Consider the Robin Laplacian with a negative boundary parameter \(\alpha\) on a locally perturbed half-space (its boundary is a hyperplane away from a bounded region). The essential spectrum is expected to be \([-\alpha^2,\infty)\). Prove or disprove that there are always negative eigenvalues below \(-\alpha^2\).

Its mathematical content is:

The source does not specify the ambient dimension, regularity, whether the zero deformation is excluded, or whether “always” means every attractive coupling and every nontrivial deformation. These distinctions matter:

- the undeformed half-space itself has no eigenvalue below its threshold; - in dimension two every sufficiently regular nontrivial deformation with the same straight line on both tails is already known to bind for every attractive coupling; - in higher dimensions the answer depends on the class of deformation, and recurrence of the tangential directions stops after ambient dimension three.

Accordingly, the intended version is taken to ask for at least one discrete eigenvalue for every attractive parameter and every **nontrivial** sufficiently regular local deformation. The result below proves this for compactly supported graph deformations in ambient dimensions two and three and gives a capacity criterion in every dimension. It does not assert a full answer for all higher-dimensional or non-graph perturbations.

To avoid a sign collision with the literature, set \(\beta=-\alpha>0\). Thus \[\partial_\nu u=\beta u, \qquad q_\beta[u]=\int_\Omega |\nabla u|^2\,dz -\beta\int_{\partial\Omega}|u|^2\,dS, \] and the flat threshold is \(-\beta^2=-\alpha^2\).

10430 | AIM-ANALYSIS-0024

Beck's solution of van den Berg's conjecture and an exact prism refinement

S / solved | AIM 研讨会问题汇编

If \(\Omega\subset\mathbb R^n\) is a convex domain, \(\rho\) and \(D\) are its inradius and diameter, and \(u\) is a first Dirichlet eigenfunction, then there should be a dimensional constant \(C_n\) such that

\[\|u\|_{L^\infty(\Omega)} \le C_n\rho^{-n/2}\left(\frac{\rho}{D}\right)^{1/6} \|u\|_{L^2(\Omega)}. \tag{1} \]

The record first recalls Chiti's estimate, which is (1) without the factor \((\rho/D)^{1/6}\), and says that Georgiev--Mukherjee--Steinerberger proved (1) for \(n=2\). It also says that the exponent \(1/6\) is suggested by a thin cone and asks even for a weaker positive power of \(\rho/D\).

The intended domain is **open, bounded, full-dimensional, and convex**. Van den Berg's original Conjecture 3 explicitly says “open, bounded convex set.” Boundedness is also needed for finite \(D\) and for the usual discrete first Dirichlet eigenvalue. A convex open set is connected. The eigenfunction may be multiplied by any nonzero scalar; (1) is invariant under that choice. We take the positive ground state.

Block-line sections and a covariance criterion for diagonal ell_p dilations

P / partially_solved | AIM 研讨会问题汇编

Let \(p>1\), let \(H\subset\mathbb R^n\) be a fixed \(k\)-dimensional linear subspace, and put

\[
D_t=\operatorname{diag}(e^{t_1},\ldots,e^{t_n}),\qquad B_p^n=\left\{x:\sum_{i=1}^n|x_i|^p\leq1\right\}. \]

\[f_H(t)=\operatorname{vol}_k(D_tB_p^n\cap H),\qquad t\in\mathbb R^n, \tag{1.1} \]

jointly log-concave?

Here \(\operatorname{vol}_k\) is Euclidean Lebesgue measure induced on the **fixed** subspace \(H\). The source remark says that \(p=1,2\) are known from Nayar--Tkocz and that the \(p=\infty\) assertion is equivalent to the logarithmic Brunn--Minkowski conjecture. Neighboring AIM records introduce no additional convention.

Two possible misreadings must be excluded:

- this is section volume, not the volume of the orthogonal projection onto \(H\); - in general \(D_tB_p^n\cap H\neq D_t(B_p^n\cap H)\), because \(D_t\) need not preserve \(H\).

For finite \(t\), the section contains a relative neighborhood of \(0\) in \(H\), so \(f_H(t)>0\) when \(k\geq1\). There is therefore no zero-volume convention hidden in log-concavity.

Boundary and Milnor obstructions to deformation into a ball

P / partially_solved | AIM 研讨会问题汇编

Let \(n\geq 3\), and let \(V\subset\mathbb C^n\) be a complex analytic subvariety of codimension one. Assume that \(0\in V\) is an isolated singularity and that \(\partial V\) is compact and smooth. Can \(V\) be “deformed” into \(\mathbb B^{\,n-1}\subset\mathbb C^{n-1}\)? A smooth deformation \((V_t,\partial V_t)\), for \(t\) in an interval \(I\), is required to have the following local descriptions. Near every \((p_0,t_0)\) with \(p_0\in V_{t_0}\), there is a function \(F(p,t)\), smooth in \((p,t)\) and holomorphic in \(p\), such that \(V_t=\{F(\cdot,t)=0\}\). Near every boundary point there is also a smooth real function \(r(p,t)\) such that locally \[V_t=\{F(\cdot,t)=0,\ r(\cdot,t)<0\}, \] and the indicated \(p\)-derivatives of \(F\) and \(r\) are linearly independent.

Conjugacy, inner cosets, and a turbulence phase diagram

P / partially_solved | AIM 研讨会问题汇编

For a separable C*-algebra A, what is the complexity of orbit equivalence relations associated to the action $\mathrm{Aut}\left(A\right) $ on itself by conjugacy and to the action of $\mathrm{Inn}\left(A\right) $ on $\mathrm{\mathrm{Au}t}\left(A\right) $ by left translation? Are these action turbulent? How are they related to structural properties of A?

Deterministic Assouad embeddings and a finite-scale stopping certificate

S / solved | AIM 研讨会问题汇编

If \((X,d)\) is doubling and \(1/2<\alpha<1\), then \((X,d^\alpha)\) admits a bi-Lipschitz embedding into \(\mathbb R^N\), where \(N\) depends on the doubling constant but is independent of \(\alpha\).

This is Problem 2.1 in the “Embeddings” section of the AIM problem list from the 2012 workshop *Mapping theory in metric spaces*.

The record writes \(\epsilon\) for the snowflake exponent. Naor--Neiman instead write the exponent as \(1-\varepsilon\), with \(0<\varepsilon<1/2\). To avoid reversing limits, this report uses \(\alpha\) for the exponent and \[s=1-\alpha \] for the loss of exponent. Thus “\(\alpha\) near one” means “\(s\) near zero.”

The source remark correctly identifies the solution by Guy David and Marie Snipes. Their arXiv preprint is titled *A constructive proof of the Assouad embedding theorem with bounds on the dimension*; the published title is *A non-probabilistic proof of the Assouad embedding theorem with bounds on the dimension* [DS]. No reconstruction of the mathematical statement was needed.

10565 | AIM-ANALYSIS-0130

Energy-jump rigidity for planar Hopf-Laplace maps

P / partially_solved | AIM 研讨会问题汇编

The exact AIM record asks about a planar Sobolev map \(f\) satisfying

\[\partial_{\bar z}\!\left(f_z\overline{f_{\bar z}}\right)=0, \qquad f\in W^{1,2}_{\mathrm{loc}},\qquad J_f\geq 0, \]

There is an important notational defect in that text. The displayed second-order equation contains the conjugate, but the next sentence says that it reduces locally to \(f_zf_{\bar z}=1\), without a conjugate. The mathematically consistent reduction is

\[F_w\overline{F_{\bar w}}=1. \tag{1.1} \]

Indeed, \(f_z\overline{f_{\bar z}}\in L^1_{\mathrm{loc}}\), and Weyl's lemma for \(\bar\partial\) gives

\[f_z\overline{f_{\bar z}}=\varphi(z) \tag{1.2} \]

for a holomorphic function \(\varphi\). Near a point where \(\varphi\ne0\), choose a branch of \(\sqrt\varphi\) and the natural coordinate

\[w=\int^z\sqrt{\varphi(\zeta)}\,d\zeta. \]

For \(F(w)=f(z(w))\), the chain rule gives

\[F_w\overline{F_{\bar w}} =f_z\overline{f_{\bar z}}(z_w)^2 =\varphi\,\frac1\varphi=1. \]

Thus (1.1), with the conjugate retained, is the local differential inclusion relevant to the question.

There is also a scope ambiguity.
Cristina--Iwaniec--Kovalev--Onninen formulate the originating open question as: “Suppose that \(h\) is an energy-minimal deformation. Is \(\lvert Dh\rvert\) continuous?” The AIM record foregrounds only finite energy and \(J_f\ge0\). This report distinguishes:

1. the **broad Hopf-solution reading**, namely (1.2), \(f\in W^{1,2}_{\mathrm{loc}}\), and \(J_f\ge0\); and 2. the **energy-minimal-deformation reading**, which adds the global deformation/minimality conditions from the source paper.

Since \(Df\) is initially defined only almost everywhere, “continuous” is understood to mean that its Frobenius norm has a continuous representative.

Equality rigidity and low-rank structure for roots of polynomial squared norms

P / partially_solved | AIM 研讨会问题汇编

The radical of the set of squared norms of polynomial mappings (proposed by John D'Angelo and Dror Varolin). Let $\mathcal P$ denote the set of Hermitian symmetric polynomials $R(z,\bar w)$, and let $\mathcal S\subset\mathcal P$ denote the set of squared norms of holomorphic polynomial mappings. For $R\in\mathcal P$, give a necessary and sufficient condition for the existence of a positive integer N such that $R^N\in\mathcal S$. In other words, when do there exist N and holomorphic polynomials p_j such that \[R(z,\bar z)^N=\sum_{j=1}^k |p_j(z)|^2? \tag{1.1} \] It is known that $R^N\in\mathcal S$ implies \[|R(z,\bar w)|^2\le R(z,\bar z)R(w,\bar w). \tag{1.2} \] This inequality can hold without R being a squared norm. Also, $R\in\mathcal S$ if and only if every matrix $[R(z_i,\bar z_j)]_{i,j=1}^k$ is nonnegative semidefinite. Equivalently, under hereditary functional calculus, $R([A],[A^*])\succeq0$ for all finite commuting square-matrix tuples $[A]=(A_1,\ldots,A_n)$.

Exact tensorization of optimal Dirichlet eigenfunction power-concavity

P / partially_solved | AIM 研讨会问题汇编

Let $\Omega\subset\mathbb R^n$ be a bounded convex domain and let u be the principal eigenfunction of the Dirichlet Laplacian on Ω. Brascamp and Lieb proved that u is log-concave. It is also known that u^α is concave for certain $\alpha>0$. Define $$ \alpha(\Omega)=\sup\{\alpha\geq 0:u^\alpha\text{ is concave}\}. $$ Lindqvist conjectured that $\alpha(\Omega)$ is maximized by the ball.

The source URL is <http://aimpl.org/shapesurface/2/>.

The eigenfunction solves $$ -\Delta u=\lambda_1(\Omega)u\quad\text{in }\Omega, \qquad u>0\quad\text{in }\Omega, \qquad u=0\quad\text{on }\partial\Omega. $$ Its positive normalization is immaterial: multiplying u by a constant multiplies u^α by a positive constant and hence does not change concavity. Translations, rotations, and uniform dilations of Ω also leave $\alpha(\Omega)$ unchanged. A general affine map does not, because it changes the Laplacian into an anisotropic operator.

Finite-jet status and a complex-locus similarity sieve

P / partially_solved | AIM 研讨会问题汇编

7. (D. Zaitsev) Let M be a real submanifold of $\mathbb C^n$ which is generically minimal and holomorphically nondegenerate. What can you say about $\operatorname{Aut}(M,p)$ at nonminimal points?

The assigned AIM record is Problem 7 of the workshop list *Emerging applications of complexity for CR mappings*. Its text is:

The line **“CR embeddings”** that follows is a new section heading. It is not part of Problem 7.

Two genuine ambiguities remain in the source.

1. It says “real submanifold,” not “real-analytic generic CR submanifold.” Holomorphic nondegeneracy and the notation used in the surrounding problems strongly suggest the real-analytic embedded CR category, but this is not stated. 2. In the standard usage of the cited literature, $$ \operatorname{Aut}(M,p) =\{\text{germs at }p\text{ of biholomorphisms }H:(\mathbb C^n,p)\to(\mathbb C^n,p), \ H(M)\subset M\}. $$ Thus it is a stability group: every element fixes p. It is not the collection of all local arrows taking p to varying points. This reading is reinforced by the immediately preceding AIM problems, which introduce separate notation $\mathcal O(p)$ for the orbit under such arrows.

This report therefore gives three answers: the established real-analytic hypersurface answer, the still-open higher-codimension answer, and the limitations of a merely smooth interpretation.

10684 | AIM-FUNCTIONAL_ANALYSIS-0027

Forcing absoluteness of minimal and separable maximal tensor products

P / partially_solved | AIM 研讨会问题汇编

Does \(\otimes_{\min}\) or \(\otimes_{\max}\) commute with forcing?

The record names no pair of C\(^*\)-algebras and gives no remarks or literature. The two preceding records ask whether the number of C\(^*\)-norms on certain algebraic tensor products, and the ideal structure of \(\mathcal B(H)\otimes_{\min}\mathcal Q(H)\), can depend on the model of set theory. This supports a model-comparison reading, but it does **not** justify silently inserting \(\mathcal B(H)\), \(\mathcal Q(H)\), or any other particular pair into Problem 3.3.

There is also a real foundational ambiguity. If \(M\subseteq N=M[G]\) is a forcing extension and \(A\in M\) is complete according to \(M\), then \(N\) may contain new Cauchy sequences in the old metric space. The convention used in later operator-algebra forcing work is to identify a ground-model C\(^*\)-algebra with its metric completion in the extension [FKV]. We adopt precisely that convention.

For a ground-model C\(^*\)-algebra \(A\), write \[A^N=\widehat{A^M}^{\,N}. \] For \(\alpha\in\{\min,\max\}\), the canonical formulation studied here is whether \[\widehat{(A\otimes_\alpha B)^M}^{\,N} \quad\hbox{and}\quad A^N\otimes_\alpha^N B^N \tag{1} \] are canonically isomorphic by the identity on the old algebraic tensor product.

This is different from recomputing a definition in \(N\). For example, the completion of the ground-model Calkin algebra need not be the Calkin algebra computed in the extension [FKV, §2]. It is also different from asking whether forcing preserves nuclearity or exactness, and from developing a Boolean-valued tensor-product functor. Those are plausible broader questions, not recovered content of the one-line AIM record.

10689 | AIM-ANALYSIS-0032

Four sharp constants and a conical affine lower bound

P / partially_solved | AIM 研讨会问题汇编

Let \(\Omega\subset\mathbb R^n\) be a convex domain and let \(f:\Omega\to[0,\infty)\) be either convex or subharmonic. Find the smallest constants in \[\frac1{|\Omega|}\int_\Omega f\,dx \leq \frac{c_n}{|\partial\Omega|}\int_{\partial\Omega}f\,d\sigma \tag{HH1} \] and \[\int_\Omega f\,dx \leq \widetilde c_n|\Omega|^{1/n}\int_{\partial\Omega}f\,d\sigma . \tag{HH2} \]

It asks the following.

Here and below, \(|\partial\Omega|=\mathcal H^{n-1}(\partial\Omega)\). The source uses the same symbols for two different function classes. This is a material ambiguity: there are actually four universal sharp constants, and one of the four is now known exactly while the other three are not all known.

The source also says that (HH2) follows from (HH1) “with \(\widetilde c_n=c_n/\sqrt n\).” Read as a choice of a sufficient, nonsharp constant, this is valid. Read as an equality between the two optimal constants, it is not justified. Section 3 gives the exact normalization relation.

The standard admissible class in the cited higher-dimensional papers is that of bounded convex domains, without a smooth-boundary restriction. Thus the conical domains used below are directly admissible. A smooth approximation argument is nevertheless included in Section 7.3.

Holomorphic Foliation Theory - Problem 12

O / open | AMR 问题清单汇编

Recently, Benjamin Weiss has proved the existence of non-trivial probability measures on $\mathscr{H}$ which are invariant by the above translation operator, see [Weiss]. These measures are studied in particular by Buhovsky, Gl\"ucksam, Logunov and Sodin [BGLS]. A measure is *non-trivial* if it gives zero measure to the set of constant maps. Using standard results from ergodic theory, one gets the existence of non-trivial ergodic measures, i.e. measures such that the only invariant measurable subsets are of zero or full measure.

Given such a measure μ on $\mathscr{H}$ as above, what we can say about $\mu(\mathscr{U})$?

Holomorphic Foliation Theory - Problem 3

O / open | AMR 问题清单汇编

Let $\mathscr{H}_d$ denote the set of foliations of degree d with only hyperbolic singularities. This is an open real Zariski dense set in $\mathscr{B}_d$. It is easy to show that $\mathscr{B}_d^{a}\cap\mathscr{H}_d$ is an analytic set [FS3] because one can bound the degree of the curve, when all singularities are hyperbolic. Let $\mathscr{B}_d^{c}$ denote the set of foliations which admit directed positive closed currents. It is clearly a closed set in $\mathscr{B}_d$. Part of Theorem 3.1 can be stated as $ \mathscr{B}_d^{c}\cap\mathscr{H}_d=\mathscr{B}_d^{a}\cap\mathscr{H}_d$.

Is the space $\mathscr{B}_d^{c}$ a countable union of proper analytic subsets of $\mathscr{B}_d$, when $d\geq2$?

10748 | AMR-135-0004

Holomorphic Foliation Theory - Problem 4 (Anosov)

O / open | AMR 问题清单汇编

Consider foliations on $\mathbb{P}^2$. Recall that $\mathscr{B}_d$ denote the space of holomorphic foliations of geometric degree d on $\mathbb{P}^2$. Let $\mathscr{A}_d$ denote the space of foliations given in an affine coordinate chart $\mathbb{C}^2$ in $\mathbb{P}^2$ by a vector field $$Z:=P(z,w) {\partial \over \partial z} + Q(z,w) {\partial \over \partial w}$$ with $\max(\deg P, \deg Q)=d$. This notion of degree is not invariant under automorphisms of $\mathbb{P}^2.$ Generically in $\mathscr{B}_d$, the foliations have no compact leaf, and generically in $\mathscr{A}_d$, the line at infinity is invariant.

For a generic foliation in $\mathscr{A}_d$ (resp. $\mathscr{B}_d$), are generic leaves biholomorphic to the unit disc ?

10750 | AMR-135-0006

Holomorphic Foliation Theory - Problem 6

O / open | AMR 问题清单汇编

The question is quite old and is due to Camacho-Lins Neto-Sad [CLS]. The problem is also discussed in [FS3]. The answer is positive if $\mathscr{F}$ admits a directed positive closed $(1,1)$-current T, in particular, when $\mathscr{F}$ has an invariant algebraic curve. The support of this current T should contain a singularity since otherwise the cohomology class of T satisfies $\{T\}^2=0$ which is impossible in $\mathbb{P}^2$. Using the leaf L, we can construct a directed positive ${dd^c}$-closed current S supported by $\overline L$. Again, for cohomological reason, one can show that S and T have to intersect and the intersection should be at the singularities as both currents are directed by the foliation. For this purpose, one can use the theory of densities for currents, see also [DS1].

Does there exist a Levi flat smooth or real analytic hypersurface in $\mathbb{P}^2$?

Let Z be a holomorphic vector field in $\mathbb{C}^2$.

(i) Is it possible to have a set of positive measure of leaves covered by $\mathbb{C}$ and another set of positive measure of leaves covered by the unit disc ?

(ii) If a non-pluripolar set of leaves are parabolic, are all leaves parabolic ?

(iii) Find conditions which imply that all leaves are covered by the unit disc.

Hot spots: high-dimensional refutation, product rules, and heat-flow quantifiers

S / solved | AIM 研讨会问题汇编

Hot spots conjecture

This conjecture is often attributed to J. Rauch, who has formulated it in terms of large-time behaviuor of the heat semigroup generated by the Neumann Laplacian. On the qualitative level, this conjecture manifests as follows: for an insulated flat piece of metal with an arbitrary initial temperature distribution, given enough time, the hottest point on the metal will lie on its boundary.

The first non-trivial Neumann eigenfunction does not have global extrema in the interior of \(\Omega\) if

1. \(\Omega\subset\mathbb R^2\) is simply connected. 2. \(\Omega\subset\mathbb R^n\) (\(n\geq 3\)) is convex.

Index one, global regularity, and Stein neighborhoods

P / partially_solved | AIM 研讨会问题汇编

Let \(\Omega\) be a smooth bounded pseudoconvex domain such that for any \(0<\eta<1\), there exists a defining function \(\rho_\eta\) such that \(-(-\rho_\eta)^\eta\) is plurisubharmonic on \(\Omega\). Note that such an \(\eta\) always exists [MR0430315]; however, it could be small. Determine minimal assumptions on \(\Omega\) to show that the \(\bar\partial\)-Neumann operator \(N\) (or the Bergman projection \(\mathbf B\)) is globally regular. Determine minimal assumptions on \(\Omega\) to show existence of a Stein neighborhood basis for the closure. Are there domains such that \(\mathbf B\) is globally regular but no such family of defining functions exists?

Index tests and quantitative boundary-root pushing for zero-free Mergelyan approximation

P / partially_solved | AIM 研讨会问题汇编

If \(\mathbb C\setminus K\) is connected and \(f\in A(K)\) has no zeros in \(K^\circ\), must \(f\) be a uniform limit on \(K\) of polynomials having no zeros on \(K\)?

The live page was checked on 2026-07-28. It attributes the problem to P. Gauthier and reads:

The phrase “Let be \(K\) be” is a source typo; the intended opening is “Let \(K\subset\mathbb C\) be compact.” The page does not specify a topology for \(p_n\to f\). The intended meaning is **uniform convergence on \(K\)**:

\[\|p_n-f\|_K:=\max_{z\in K}|p_n(z)-f(z)|\longrightarrow0. \]

This reconstruction is verified by the precise formulations in Andersson, Gauthier--Knese, Khrushchev, and Danielyan. It is also confirmed internally by adjacent AIM Conjecture 9.2, which uses \(\|\cdot\|_{\infty,K}\) and says that Andersson proved its equivalence to Problem 9.1.

\[A(K)=C(K)\cap\mathcal O(K^\circ). \]

The recovered question is therefore:

10763 | AIM-ANALYSIS-0089

Induced ell-p paving endpoints and simultaneous all-p conference paving

P / partially_solved | AIM 研讨会问题汇编

For every \(\varepsilon>0\), is there an integer \(k=k(\varepsilon,p)\), independent of \(n\), such that every zero-diagonal \(n\times n\) matrix \(A\) with \(\|A\|_p=1\) has a partition \([n]=\sigma_1\sqcup\cdots\sqcup\sigma_k\) satisfying \[\left\|\sum_{j=1}^kP_{\sigma_j}AP_{\sigma_j}\right\|_p =\max_j\|P_{\sigma_j}AP_{\sigma_j}\|_p\leq\varepsilon? \]

The record is Bill Johnson's question from the AIM workshop *Beyond Kadison--Singer: paving and consequences*. It asks, for \(1\leq p<\infty\):

The source has the typographical fragment `\|\dot\|_`; its following prose explicitly says that this is the **operator norm on \(\ell_p^n\)**. Accordingly, throughout this report \[\|A\|_{p\to p}:=\sup_{x\ne0}\frac{\|Ax\|_p}{\|x\|_p}. \] This is not the Schatten norm \((\operatorname{tr}|A|^p)^{1/p}\). We write \(R_p(\varepsilon)\) for the least uniform number of blocks, when it exists, and \(p'=p/(p-1)\), with \(1'=\infty\).

The displayed equality in the question is correct, but it needs a Banach-space justification rather than a Hilbert-space orthogonality argument. If \(B_j=P_{\sigma_j}AP_{\sigma_j}\), then \(\ell_p^n=(\bigoplus_j\ell_p(\sigma_j))_p\) and \(\sum_jB_j=\bigoplus_jB_j\). Hence, for \(1\leq p<\infty\), \[\left\|\bigoplus_jB_jx_j\right\|_p^p \leq \bigl(\max_j\|B_j\|_{p\to p}\bigr)^p\sum_j\|x_j\|_p^p. \] The reverse inequality follows by taking a norming (or approximately norming) vector supported in one maximizing block. Thus \[\left\|\sum_jP_{\sigma_j}AP_{\sigma_j}\right\|_{p\to p} =\max_j\|P_{\sigma_j}AP_{\sigma_j}\|_{p\to p}. \] The same equality holds for \(p=\infty\).

Literal and boundary counterexamples for Hermitian sums of squares

S / solved | AIM 研讨会问题汇编

1. Sums of squares of polynomials. (Proposed by John D'Angelo) Let \(\Omega\subset\mathbb C^n\) be a strongly pseudoconvex domain with compact algebraic boundary. Let \(R(z,\overline z)\) be a real polynomial which is positive on the boundary of \(\Omega\). Does there exist a positive integer \(k\) and polynomials \(p_1(z),p_2(z),\ldots,p_k(z)\) such that \[R(z,\overline z)=\sum_{j=1}^k |p_j(z)|^2 \] on \(\Omega\)? The answer is known to be yes if \(\Omega\) is the unit ball in \(\mathbb C^n\). (See [CD].)

Monotone Galerkin approximation of finite Schur complements

P / partially_solved | AIM 研讨会问题汇编

A problem analogous to Problem 1.10.3 was solved in [5] by showing that Second Order Cone Programming is poly.-time equivalent to Linear Programming.

1.11 Hugo Woerdeman. One of the questions I am interested in is how to approximate numerically the Schur complement of a positive definite operator supported on a finite subspace. Of course there is the formula that for a block matrix \[\begin{pmatrix}A&B\\ C&D\end{pmatrix} \] the Schur complement is \(A-BD^{-1}C\), but this requires determining the inverse of the infinite operator \(D\). The way this question arose is through attempts to develop multivariable analogs of the Gohberg--Semencul formula. One way to prove the Gohberg--Semencul formula is by determining the Schur complement of the inverse of a Toeplitz operator whose symbol is the reciprocal of a positive trigonometric polynomial. In several variables the analogous attempt runs into difficulties. In order to at least get a decent numerical approximation of the inverse of a doubly Toeplitz matrix, one may try to find reasonable numerical methods to determine finitely based Schur complements of infinite operators.

Normalization and the constant-one multilinear Kakeya question

P / partially_solved | AIM 研讨会问题汇编

The official TeX says that, for collections \(\mathcal T_i\) of doubly infinite tubes of width one in \(\mathbb R^n\),

\[\int \left[\left(\sum_{T_1\in\mathcal T_1}\chi_{T_1}\right)\cdots \left(\sum_{T_n\in\mathcal T_n}\chi_{T_n}\right) w(T_1)\wedge\cdots\wedge w(T_n) \right]^{1/(n-1)} \le C_n\prod_{i=1}^n(\#\mathcal T_i)^{1/(n-1)}, \tag{0.20} \]

and asks whether one can take \(C_n=1\).

As typeset, the symbols \(T_i\) in the wedge factor are free: they occur outside the displayed sums. The primary theorem from which the display comes, Carbery--Valdimarsson [CV13, Theorem 1], and the later explicit display in Bennett--Iliopoulou [BI18, p. 1095], show that the intended left side is the following \(n\)-fold weighted sum. Put \(p=1/(n-1)\) and

\[F_{\boldsymbol{\mathcal T}}(x) :=\sum_{(T_1,\ldots,T_n)\in\mathcal T_1\times\cdots\times\mathcal T_n} \left|\det\bigl(w(T_1),\ldots,w(T_n)\bigr)\right| \prod_{i=1}^n\mathbf 1_{T_i}(x). \tag{1} \]

The recovered question is therefore

\[\mathcal K_n(\boldsymbol{\mathcal T}) :=\int_{\mathbb R^n}F_{\boldsymbol{\mathcal T}}(x)^p\,dx \stackrel{?}{\le} \prod_{i=1}^n(\#\mathcal T_i)^p. \tag{2} \]

Here the wedge is the **unsigned** volume of the parallelotope, as in [CV13]. Without the absolute value, a fractional power need not even be real.

There is a second source ambiguity that is decisive for the number \(1\): neither the problem TeX nor the PDF defines “width one.” In [CV13, pp. 1644--1645], a \(1\)-tube means the \(1\)-neighbourhood of a line, hence a round tube of radius one and total transverse width two. Other formulations normalize a tube's \((n-1)\)-dimensional cross-sectional volume to one; [BI18, p. 1094] explicitly uses that convention. These conventions differ by a dimensional factor that cannot be ignored in a best-constant question.

Open Problems in Pluripotential Theory - Question 41

O / open | AMR 问题清单汇编

When S_0 has some non-zero Lelong numbers, DiNezza and Lu construct a maximal family of positive currents $(\omega_t)_{0<t<T_{max}}$ which are honest K\"ahler forms on a time-increasing family of Zariski open subsets Ω_t where they satisfy the K\"ahler-Ricci flow equation. By analogy with Demailly regularization results [Dem92,Dem93], it is natural to expect that this family has analytic singularities.

[DiNezza-Lu] Does the K\"ahler-Ricci flow produce approximants with analytic singularities ?

Open Problems in Wavelet Theory - Problem 11

O / open | AMR 问题清单汇编

A variant of Problem 3.1 asks for a characterization of dilations for which well-localized o.n. wavelets exist. We say that a function $\psi \in L^2(\mathbb{R}^n)$ is *well-localized* if both ψ and $\hat \psi$ have polynomial decay. That is, for some large $N>0$, we have \[\psi(x) = O(|x|^{-N}) \text{ as } |x| \to \infty \qquad\text{and}\qquad \hat \psi(\xi) = O(|\xi|^{-N}) \text{ as } |\xi| \to \infty. \]

Let $\Gamma={\mathbb{Z}}^n$ be the lattice of translates. For what expansive dilations A do there exist well-localized wavelets (possibly with multiple generators)?

Open Problems in Wavelet Theory - Problem 3

O / open | AMR 问题清单汇编

This leaves open the problem of existence of Riesz wavelets which was posed by Seip [Seip]. We say that ψ is a Riesz wavelet for $\mathcal{H} =H^2(\mathbb{R})$ or $L^2(\mathbb{R})$ if the wavelet system is a Riesz basis of $\mathcal{H}$. A Riesz basis in a Hilbert space $\mathcal{H}$ can be defined as an image of an orthonormal basis under an invertible operator on $\mathcal{H}$. Every Riesz basis has a dual Riesz basis. However, the dual of Riesz wavelet system might not be a wavelet system. If it is, then we say that ψ is a biorthogonal (Riesz) wavelet.

Does there exist a Riesz wavelet ψ in $H^2(\mathbb{R})$ such that ψ belongs to the Schwartz class?

背景链接：https://arxiv.org/abs/1905.08230

10919 | AMR-155-0004

Open Problems in Wavelet Theory - Problem 4

O / open | AMR 问题清单汇编

Larson [La2] has posed an interesting problem about frequency supports of wavelets. Must the support of the Fourier transform of a wavelet contain a wavelet set? This problem stems from the observation that there are two ways of describing minimality of frequency support. The first one is that $\operatorname{supp} \hat \psi$ has the smallest possible Lebesgue measure (equal to 1), which is used in the actual definition of an MSF wavelet. The second possibility is to insist that the support is minimal with respect to the inclusion partial order. It is not known whether these two natural definitions of minimality of frequency supports are the same. This is the essence of the following problem posed by Larson in late 1990's although its official formulation appeared only in [La2].

Is it true that for any orthonormal wavelet $\psi \in L^2(\mathbb{R})$, there exists a wavelet set W such that such that $W \subset \operatorname{supp} \hat\psi$?

Open Problems in Wavelet Theory - Problem 6

O / open | AMR 问题清单汇编

Suppose that $\psi \in L^2(\mathbb{R}^n)$ is a Parseval wavelet. Then, we can define spaces $$ V_j = D^j(V(\psi)) \qquad j\in {\mathbb{Z}}, $$ where $Df(x)=\sqrt{2} f(x)$ is a dilation operator. Baggett has shown that a sequence $\{V_j:j\in{\mathbb{Z}}\}$ satisfies all properties of GMRA (M1), (M2), (M4), and (M5') possibly with the exception of (M3). Hence, it is natural to ask the following question.

Let ψ be a Parseval wavelet with the space of negative dilates $V=V(\psi)$. Is it true that $$ \bigcap_{j\in{\mathbb{Z}}} D^j(V(\psi))=\{0\}? $$

10964 | AIM-ANALYSIS-0075

Pure-state extension from a MASA of a factor

P / partially_solved | AIM 研讨会问题汇编

QUESTION 2. Given a MASA \(A\) of a factor \(M\), do the pure states of \(A\) have unique state extension to \(M\)?

The compilation is dated November 30, 2014.

The question is:

The source then records: a positive answer for discrete MASAs of \(B(H)\) when \(H\) is separable (by Marcus--Spielman--Srivastava); a negative answer when the MASA has a continuous part; a negative answer for all MASAs in type II factors on separable \(H\); mixed behavior for nonseparable type II factors; and “no results at all” for type III factors.

The quantifier in the question is important. It asks whether **every** pure state of \(A\), including singular pure states, has exactly one state extension to \(M\). It does not ask whether a particular pure state has a unique extension, and it does not ask only about normal states.

Rank spectra for Hermitian squared norms divisible by norm powers

P / partially_solved | AIM 研讨会问题汇编

Let \(R(z,\bar z)\) be a Hermitian polynomial which is a sum of squares \[R(z,\bar z)=\sum_{j=1}^{m}|p_j(z)|^2, \] where the holomorphic polynomials \(p_j\) are linearly independent. If \(R=\|z\|^2A\), what are the possible values of \(m\)? Huang's lemma implies that \(m=0\) or \(m\ge n\). Consider the same question with \(\|z\|^{2d}\).

The two MathSciNet citations were recovered exactly.

- MR1703603 is Xiaojun Huang, “On a linearity problem for proper holomorphic maps between balls in complex spaces of different dimensions,” *Journal of Differential Geometry* 51 (1999), 13--33. The lemma used by AIM is the rank obstruction for a nonzero expression divisible by \(\|z\|^2\). - MR2869101 is John P. D'Angelo and Jiří Lebl, “Pfister's theorem fails in the Hermitian case,” *Proceedings of the American Mathematical Society* 140 (2012), 1151--1157. Its Theorem 2.1 is the requested higher-power generalization.

The canonical record itself is internally coherent and the primary papers remove any ambiguity about \(d\): \(d\) is a positive integer and \[\|z\|^{2d}=\left(\sum_{i=1}^n |z_i|^2\right)^d. \] No homogeneity of \(R\), \(A\), or the \(p_j\) is stated. Importantly, the D'Angelo--Lebl bound applies even to real-analytic, nonhomogeneous multiples.

For any function $f(z)$ in the plane, let $n(r)=\sup_a n(r,a)$ be the maximum number of roots of the equation $f(z)=a$ in $|z|<r$, and \[A(r) = \frac{1}{\pi}\int\int_{|z|<r}\frac{|f'(z)|^2}{\{1+|f(z)|^2\}^2}\,dx\,dy = \frac{1}{\pi}\int\int_{|a|<\infty}\frac{n(r,a)\,|da|^2}{(1+|a|^2)^2}.\] Then $\pi A(r)$ is the area, with due count of multiplicity, of the image on the Riemann sphere of the disc $|z|<r$ under f, and $A(r)$ is the average value of $n(r,a)$ as a moves over the Riemann sphere. It is known (see Hayman) that \[1\leq\liminf_{r\to\infty}\frac{n(r)}{A(r)}\leq e.\] Can e be replaced by any smaller quantity, and in particular, by 1?

How big can the set of Valiron deficiencies be for functions in the plane? It is known that $$ N(r,a)=T(r,f)+O\big(T(r,f)^{\frac{1}{2}+\varepsilon}\big) $$ as $r\to\infty$, for all a outside a set of capacity zero (see Nevanlinna . In the case $R<+\infty$ this is more or less best-possible, but in the plane we only know from an example of Valiron that the corresponding set of a can be non-countably infinite. It is also not known whether ([source label: 1.3]) can be sharpened.

Research Problems in Function Theory - Problem 1.23

P / partially_solved | AMR 问题清单汇编

Under what circumstances does $f(z_0+z)$ have the same deficiencies as $f(z)$? It was shown by Dugu{\'e} that this need not be the case for meromorphic functions, and by Hayman that it is not necessarily true for entire functions of infinite order. The case of functions of finite order remains open. Valiron notes that a sufficient condition is \[\frac{T(r+1,f)}{T(r,f)}\to 1, \hspace{1cm}\text{ as }r\to\infty,\] and this is the case in particular if $\rho-\lambda<1$. Since for entire functions of lower order λ, $\lambda\leq\frac{1}{2}$ there are no deficiencies anyway, it follows that the result is true at any rate, for entire functions of order $\rho<\frac{3}{2}$ and, since $\lambda\geq0$ always, for meromorphic functions of order less than one.

The analogue of Problem 1.7 may be asked for meromorphic functions. The proposers conjecture that in this case \[\sum\delta(a,f)\leq\max\{\Lambda_1(\rho),\Lambda_2(\rho)\},\] where for $\rho\geq1, q=[2\rho]$ we have \[\Lambda_1(\rho)=2-\frac{2\sin\big(\frac{1}{2}\pi(2\rho-q)\big)}{q+2\sin\big(\frac{1}{2}\pi(2\rho-q)\big)},\] \[\Lambda_2(\rho)=2-\frac{2\cos\big(\frac{1}{2}\pi(2\rho-q)\big)}{q+1}.\] Weitsman shows that this result would be sharp. The correct bound is known for $0\leq\rho\leq1$. (D. Drasin and A. Weitsman)

If $f(z)$ is meromorphic of finite order ρ and $\sum\delta(a,f)=2$, it is conjectured that $\rho=n/2$, where n is an integer and $n\geq 2$, and all the deficiencies are rational. F. Nevanlinna has proved this result on the condition that $f(z)$ has no multiple values, so that $n(r,a)=\overline{n}(r,a)$ for every a (see also R. Nevanlinna).

Let the function f be meromorphic in the plane, and not rational, and satisfy the condition $$ \frac{T(r,f)}{(\log r)^3}\to\infty,\hspace{1cm}\text{ as }r\to\infty, $$ where $T(r,f)$ is the Nevanlinna characteristic. A theorem of Yang Lo states that then there exists a direction $\theta_0\in[0,2\pi)$ such that for every positive ε, either f attains every finite value infinitely often in $D_\varepsilon=\{z:|\arg z - \theta_0|<\varepsilon\}$, or else $f^{(k)}$ attains every value, except possibly zero, infinitely often in D_ε for all positive integers k. Can the condition ([source label: star]) be dropped completely? Or, possibly, can it be replaced be the `more usual' condition \[\frac{T(r,f)}{(\log r)^2}\to\infty,\hspace{1cm}\text{ as }r\to\infty\,?\] One cannot expect any more from Yang Lo's method of finding $\theta_0$ through the use of `filling discs'. Rossi has shown that ([source label: star]) cannot be improved if θ_0 is sought in this way. (D. Drasin; communicated by J. Rossi)

Determine the upper and lower estimates for the growth of entire and meromorphic solutions of algebraic ordinary differential equations (AODE). (This is a classical problem.) For AODEs of first order, it is known that the meromorphic solutions f must have finite order (see Gol'dberg) and that $(\log r)^2=O(T(r,f))$ (see Eremenko ,). (The latter two references contain a general account of first order AODEs, including modern proofs of some classical results.) The order of entire solutions of first order AODEs is an integral multiple of $\frac{1}{2}$ (see Malmquist). For AODEs of second order, it is known that the order of entire solutions is positive, see Zimogljad . There is no upper estimate valid for all entire or meromorphic solutions of AODEs of order grreater than one, but there is an old conjecture that $\log |f(z)|\leq exp_n(|z|)$ for entire solutions f of an AODE of order n. If $f(z)$ is an entire function of finite order ρ which is not an integer, it is known that (see Pfluger and Hayman), \[\sum \delta(a,f)\leq 2-K(\rho)\] where $K(\rho)$ is a positive quantity depending on ρ. What is the best possible value for $K(\rho)$? Edrei and Fuchs conjectured (see also Hayman) that if q is the integral part of ρ, and if $q\geq1$, then \[K(\rho)=\frac{|\sin(\pi\rho)|}{q+|\sin(\pi\rho)|},\hspace{1cm}q\leq\rho<q+\frac{1}{2},\] \[K(\rho)=\frac{|\sin(\pi\rho)|}{q+1},\hspace{1cm}q+\frac{1}{2}\leq\rho<q+1.\] This result would be sharp. If $\rho\leq\frac{1}{2}$, there are no deficient values, so that $K(\rho)=1$. If $\frac{1}{2}<\rho<1$, Pfluger proved that $K(\rho)=\sin(\pi\rho)$. See also Hayman .

What is the least integer $k=k(N)$, such that every entire function $f(z)$ can be written as \[f(z)=\sum^k_{\nu=1}[f_\nu(z)]^N,\] where $f(z)$ and $f_\nu(z)$ are entire functions? It is enough to solve the problem for $f(z)=z$, since then one can substitute $f(z)$ for z. The equation \[z=\frac{1}{N^2}\sum^N_{\nu=1}\frac{(1+\omega_\nu z)^N}{\omega_\nu},\] where ω_ν are the distinct N-th roots of unity, shows that $k(N)\leq N$. On the other hand, for $N=1, 2, 3$ we have $k(N)=N$. To see e.g. that $k(3)\geq 3$, suppose that \[z=f^3+g^3=(f+g)(f+\omega g)(f+\omega^2 g),\] where $\omega=exp(2\pi i/3)$. It follows that the meromorphic function $\phi(z)=f(z)/g(z)$ satisfies $\phi(z)\neq-1, -\omega, -\omega^2$, except possibly at $z=0$. Thus, by Picard's Theorem, $\phi(z)$ must be rational, and so $\phi(z)$ assumes at least two of the three values $-1, -\omega, -\omega^2$. This gives a contradiction. (H.A. Heilbronn)

Suppose that $0<\rho<\alpha\leq1$, where ρ is the order of an entire function f. Let E_α be the set of r for which $\log m_0(r,f)>\cos (\pi\alpha) \log M(r,f)$. Besicovitch showed that the upper density of E_α is at least $1-\rho/\alpha$, and Barry proved the stronger result, that the same is true of the lower logarithmic density of E_α. Examples given by Hayman , show that Barry's theorem is sharp; in these examples, the logarithmic density exists, but the upper density is larger. This suggests that Besicovitch's theorem may be sharpened.

We can also compare $m_0(r,f)$ with the characteristic $T(r)$. We have \[\limsup_{r\to\infty}\frac{\log m_0(r,f)}{T(r)}\geq D(\lambda)\] and ask for the best constant $D(\lambda)$. In view of Petrenko's solution of Problem 1.17, we certainly have $D(\lambda)\geq-\pi\lambda$ with $1\leq\lambda<\infty$. Also, Ess\'en and Shea show that $D(\lambda)\leq\frac{\pi\lambda}{1+|\sin(\pi\lambda)|}$ for $1<\lambda<\frac{3}{2}$, and $D(\lambda)\leq\frac{-\pi\lambda}{2}$ for $\frac{3}{2}<\lambda<\infty$. Further, it follows from results of Valiron , and Edrei and Fuchs (and) that \[D(\lambda)= \begin{cases} \pi\lambda\cot(\pi\lambda) & \text{if }0\leq\lambda<\frac{1}{2} \pi\lambda\cos(\pi\lambda) & \text{if }\frac{1}{2}\leq\lambda<1. \end{cases} \] (D. Shea)

Let $f(z)$ be a transcendental entire function which permutes the integers, i.e. gives an injective mapping of the integers onto themselves. Is it true that $f(z)$ is at least of order 1, type π? We can also ask the corresponding question for a function permuting the positive integers with the same conjectured answer. Note that $f(z)=z+\sin z$ satisfies both conditions and is of order 1, type π. If $f(z)$ assumes integer values on the positive integers, then Hardy and P\'olya proved (see) that $f(z)$ is at least of order 1, type 2; and if $f(z)$ assumes integer values on all the integers, then Buck has shown that $f(z)$ is at least of order 1, type $\log(\frac{3+\sqrt{5}}{2})=0.962\ldots$. Let $\{f_\alpha(z)\}$ be a family of entire functions, and assume that for every z_0, there are only denumerably many distinct values of $f_\alpha(z_0)$. Then if $c=2^{\mathfrak{N}_0}>\mathfrak{N}_1$, the family $\{f_\alpha(z)\}$ is itself denumerable. The above result was proved by Erd\"os . If $c=\mathfrak{N}_1$, he constructed a counter-example. Suppose now that m is an infinite cardinal, $\mathfrak{N}_0<m<c$. Assume that for every z_0, there are at most m distinct values $f_\alpha(z_0)$. Does it then follow that the family $\{f_\alpha(z)\}$ has at most power m? If $m^+<c$, where m^+ is the successor of m, it is easy to see that the answer is `yes'. However, if $c=m^+$, the counter-example fails. It is possible the question is undecidable. (P. Erd\"os)

If A, B are countable dense subsets of $\mathbb{R}$, $\mathbb{C}$ respectively, does there necessarily exist a transcendental entire function that maps A onto B, and $\mathbb{R} \setminus A$ into $\mathbb{C} \setminus B$? Suppose that E, F are countable dense subsets of $\mathbb{R}$, and that there exists an entire function f, monotonic on $\mathbb{R}$, that maps E onto F, and $\mathbb{R}\setminus E$ onto $\mathbb{R}\setminus F$. Find interesting conditions which imply that f is trivial. For example, if E, F are real rationals, under what conditions is f necessarily linear with rational coefficients? One could also investigate this question in the case of real-valued harmonic or subharmonic functions in $\mathbb{R}^n$, $n\geq2$. If A, B are two countable dense subsets of $\mathbb{R}$, Barth and Schneider have shown that there exists a transcendental entire function, monotonic on $\mathbb{R}$, that maps A onto B and $\mathbb{R}\setminus A$ onto $\mathbb{R}\setminus B$; also, if A,B are countable dense subsets of $\mathbb{C}$, see Barth and Schneider . For entire or, more generally, meromorphic functions f and g, let `$f\leq g$' mean that, for any sequence $\{z_n\}^\infty_1$ for which $|f(z_n)|\to\infty$, then $|g(z_n)|\to\infty$. For entire functions, it can be proved that, if $f'\leq f$, then f is of exponential type; what can be said if $f''\leq f$? Does $f''\leq f$ imply that f is normal (that is, that $|f'(z)|(1+|f(z)|^2)^{-1}$ is bounded)? (An analogue in the case of the unit disc $\mathbb{D}$ has been proved by Pommerenke). In the above ordering, does there exist $f\wedge g$ and $f\vee g$ for any two entire functions f and g? That is, given f and g, does there exist an h such that $h\leq f$ and $h\leq g$, and so that if $k\leq f$ and $k\leq g$, then $k\leq h$? Similarly, for $f\vee g$. Finally, if f is meromorphic and $f'\leq f$, does this imply a growth restriction on f, e.g. is the order of f at most two? Note: Any constant c satisfies $c\leq f$ for all entire f, and any non-constant polynomial p satisfies $f\leq p$ for any entire f. Observe also that e^{cz} are all equivalent if $c>0$. (L. A. Rubel and J. M. Anderson)

Let Γ be a rectifiable curve. Suppose f is a continuous function on the plane satisfying \[\int_{\sigma(\Gamma)}f(z)dz=0\hspace{1cm}\text{ for all rigid motions }\sigma.\] Does this imply that f is an entire function? The answer is `yes' for some choices of $\Gamma$, and `no' for others. For example, the answer is `no' for the circle ($f(x+iy)=\sin(ax)$ is a counter-example for a suitable choice of $a$); `yes' for an ellipse; `yes' for any polygonal Jordan curve; and `yes' for the boundary of any convex set with at least one corner. Prove that the circle is the only closed rectifiable Jordan curve (or the only curve among the class of curves which are boundaries of bounded convex sets) for which the answer is `no'. This problem is related to the `Pompeiu Problem' discussed by Brown, Schreiber and Taylor . (L. Brown)

Suppose that $u(X)$ is harmonic on the unit ball $|X|<1$, and remains continuous with partial derivatives of all orders on $|X|=1$, where X is a point (x_1, x_2, x_3) in space, and \[|X|^2=x^2_1+x^2_2+x^2_3.\] Suppose further that there is a set E of positive area on $|X|=1$, such that both u and its normal derivative vanish on E. Is it true that $u\equiv0$? Here the two-dimensional analogue is almost trivial, since if u is harmonic in $\mathbb{D}$, and u and its partial derivatives remain continuous on the unit cirlce $\mathbb{T}$, we may consider \[f(z)=z\Big(\frac{\partial u}{\partial x}-i\frac{\partial u}{\partial y}\Big), \hspace{1cm}\text{ where }z=x+iy.\] If $u(z)$ and its normal derivatives both vanish on a set E, then $f(z)$ vanishes at all limit points of E. Now the Poisson-Jensen formula shows at once that $\log|f(z)|=-\infty,f(z)=0,$ identically in $\mathbb{D}$, provided that the closure of E has positive 1-dimensional measure. (L. Bers)

Let $u(x)$ be subharmonic in $\mathbb{R}^m$. One can define the quantities $n(r, 0), N(r, 0), T(r)$ as in Nevanlinna theory in the plane, taking the analogue of the case $u(z) = \log|f(z) |$, where $f(z)$ is an entire function (see, for example Hayman). Define \[\delta(u) = 1 - \limsup_{r\to\infty}\frac{N(r,u)}{T(r)}.\] If the order ρ of u is less than 1, it is possible to obtain the sharp upper bound for $\delta(u)$ in terms of ρ and m. The bound is attained when $u(x)$ has all its mass on a ray (see Hayman and Kennedy). One can ask the corresponding question for $\rho > 1$. One can ask whether a lower bound $A(\rho)$ can be obtained for $\delta(u)$ if $\rho > 1$ and all the mass of $u(x)$ lies on a ray, or more generally on some suitable lower dimensional subspace S of $\mathbb{R}^m$ and $\rho>\rho_0(S)$. For fixed S we may conjecture by analogy with the case $m = 2$, that $A(\rho)\to1$ as $\rho\to\infty$. This is proved by Hellerstein and Shea in the case $m = 2$. (D. Shea)

Let D be an unbounded domain in $\mathbb{R}^n$, $n\geq 2$. Points in $\mathbb{R}^n$ will be denoted by $x = (x_1,x_2,\ldots,x_n)$, and $|x|$ will denote the Euclidean norm of x. The following result was given by Ess\'en . \begin{theorem} Assume that the least harmonic majorant Ψ of $|x_1|$ in D is such that $\Psi(x)=O(|x|)$ as $x\to\infty$ in D. If $|x|$ has a harmonic majorant in D, then $|x_1|\log^+|x_1|$ has a harmonic majorant in D. \end{theorem} In the plane, $|x|^p$ (if $p > 0$) has a harmonic majorant in D, if and only if $F\in H^p$, where $F:\{|x| < 1\} \to D$ is a universal covering map with $F(0) = 0$. There are similar statements for $|x_1|\log^+|x_1|$ and $\text{Re}\, F\in L\log L$. Thus, when $n = 2$, Theorem 1 is closely related to the following. \begin{theorem} Suppose that $n = 2$, and that $F\in H^1(\mathbb{D})$ (where $\mathbb{D}$ is the unit disc). Then $\text{Re}\, F\in L\log L$ if and only if $$ \int^\infty_{-\infty}N(1,iv,F)\log^+|v|\,dv<\infty, $$ where $N(1,\omega,F)$ is the Nevanlinna counting function (see). \end{theorem} Theorem 2 is an extension of a well-known result of Zygmund. Note also that, in the case $n = 2$, there are functions F in $H^1(\mathbb{D})$ such that $\text{Re}\, F\notin L\log L$, see . [(a)] ; In the case $n=2$, what is the relation between the condition on Ψ in Theorem 1 and condition ([source label: Jstar]) in Theorem 2? ; Suppose now that $n\geq2$. The assumption on Ψ in Theorem 1 was introduced in the proof for purely technical reasons. Is this the correct condition needed in Theorem 1 (we assume always that $|x|$ has a harmonic majorant in D)? Does there exist a domain D such that $|x|$ has a harmonic majorant in D while $|x_1|\log^+|x_1|$ does not have a harmonic majorant in D? (M. Ess\'en)

If f is any polynomial or rational function of degree N, find the least upper bound $\phi(N)$ of \[\frac{1}{r}\int^r_0dt\int^\pi_{-\pi}\frac{|f'(re^{i\theta})|}{1+|f|^2}\,d\theta,\] for varying r and f. It is known only that $\phi(N)=O(N^{\frac{1}{2}})$, $\phi(N)\neq O(\log N)^{\frac{1}{2}-\varepsilon}$, as $N\to\infty$. The upper bound for varying f of \[\int^\infty_0dt\int^\pi_{-\pi}\frac{|f'|}{1+|f|^2}\,dr\,d\theta\] should not be much larger than $\phi(N)$, but there is no proof that it is not $+\infty$. The special cases $N=2, 3, \ldots$ would be of interest. See Littlewood .

Let $\mathcal{P}$ denote the set of all polynomials of the form \[p(z)=\prod^n_{\nu=1}(z-\zeta_\nu),\] where $n\geq2$ and $|\zeta_\nu|\leq1$, $\nu=1, 2, \ldots, n$. The Sendov conjecture (see Problem 4.5) states: if $p(z)\in\mathcal{P}$ then each disc \[\{z:|z-\zeta_\nu|\leq1\},\hspace{1cm} \nu=1, 2, \ldots, n,\] contains at least one zero of $p'(z)$. Schmeisser proved this conjecture for certain subsets of $\mathcal{P}$. In all but two of these special cases, the proof show that the following stronger result is true: \textit{If ζ is an arbitrary point of the convex hull of the zeros of $p(z)$, then the disc \mbox{$\{z:|z-\zeta|\leq1\text{ contains at least one zero of }p'(z)\}$}}. We ask: [(a)] ; is this stronger result true for all $p(z)$ in $\mathcal{P}_1$, where $\mathcal{P}_1$ is the subset of all polynomials in $\mathcal{P}$ which vanish at 0? ; is this stronger result true for all $p(z)$ in $\mathcal{P}_2$, where $\mathcal{P}_2$ is the subset of all polynomials in $\mathcal{P}$ which are of the form $p(z)=z^n+a_{n-1}z^{n-1}+\ldots+a_0$, $a_\nu\leq0$, $\nu=0, 1, \ldots, n-1$? Erd\"os and Newman conjectured that if $$ f(z)=\sum^n_{k=0}a_kz^k,\hspace{1cm} |a_k|=1, \hspace{1cm}0\leq k\leq n, $$ then there is an absolute constant c such that $$ \max_{|z|=1}|f(z)|>(1+c)n^{1/2}. $$ The weaker form of our conjecture stated that ([source label: D2]) holds if we assume \linebreak \mbox{$a_k=\pm1$} (Problem 4.13). A stronger form would be that ([source label: D2]) holds even if \mbox{$f(z)=\sum^n_{k=1}a_{n_k}z^{n_k}$}, n_k natural numbers, $|a_{n_k}|=1$. However, ([source label: D2]) was disproved by Kahane (no citation). In fact, he showed that, given that $\varepsilon>0$, there are polynomials of the form ([source label: D1]) for which $$ \max_{|z|=1}|f(z)|<n^{1/2}+O(n^{(3/10)+\varepsilon})\hspace{1cm}\text{ as }n\to\infty. $$ Show that $n^{(3/10)+\varepsilon}$ cannot be replaced by n^ε in ([source label: D3]). Is there any n-th degree polynomial of the form ([source label: D1]) for which $$ \min_{|z|=1}|f(z)|>(1-\varepsilon)n^{1/2} $$ for every positive ε if $n>n_0(\varepsilon)$? Perhaps there is an n-th degree polynomial of the form ([source label: D1]), for which, for all z, $|z|=1$, $$ (1-\varepsilon)n^{1/2}<|f(z)|<(1+\varepsilon)n^{1/2}. $$ In fact, ([source label: D5]) could possibly hold with $n^{1/2}+O(1)$ on the left and right. It would be worthwhile to determine if ([source label: D2]) holds for $a_k=\pm1$ and for $a_{n_k}=\pm1$. (P. Erd\"os and D. Newman)

Let $D=D_0$ be a domain, $g(z,a_0)$ be the Green's function of D with respect to a point a_0 on the positive real axis, and let D_λ be the part of D where $g>\lambda$ for $0<\lambda<\infty$. Is it true, at least in some simple cases, that $(D_\lambda)^*\subset(D^*_\lambda)$? The cases where D^* consists of the plane or the unit disc cut along the negative real axis are of particular interest. A positive answer to this problem for simply-connected domains D would lead to a positive answer of Problem 5.16 for the same class of domains, using a formula of Hardy-Stein-Spencer (see Hayman). With the general notation of the introduction above, when can we assert that $|a_n|\leq|a_n^*|$ for general n? This is true, for instance, when D^* is the plane cut along the negative real axis, so that we obtain the Littlewood conjecture that $|a_n|\leq4|a_0|n$ for non-zero univalent f. In fact, $|a_1|\leq4|a_0|$ in this case, by symmetrisation and subordination, and $|a_n|\leq n|a_1|$ by De Branges' proof of the Bieberbach conjecture (see Update 6.1). If D is convex and $D=D^*$, the exact bound for $|a_n|$ is $|a_1|$, but $|a_n^*|\leq|a_1|$ in general (see Hayman).

Describe similarly the coefficient multipliers from S to S, where S is the class of functions $\sum^\infty_{n=1}a_nz^n$ univalent in $\mathbb{D}$ either [(a)] ; with the normalisation $a_1 = 1$, or\ ; generally. ; What are the multipliers of the space of close-to-convex functions into itself? ; What are the multipliers of S into the class C of convex functions? ; What are the multipliers from the class N of functions of bounded characteristic into itself? The analogous problem for the class N^+ may be more tractable. (The definition of N^+ is too lengthy for this work, but the reader is directed to Duren for more details). Ruscheweyh and Sheil-Small in solving Problem 6.9 have shown that (λ_n) is a multiplier sequence from C into itself if and only if $\sum\lambda_nz^n\in C$. In general, one can obtain only some sufficient conditions. Thus in most cases $f(z) = \sum a_n z^n$ belongs to a class A if a_n is sufficiently small, and conversely if $f\in A$, then a_n cannot be too big. For example, $\sum^\infty_2n|a_n|\leq1$ is a sufficient condition for $f(z)$ in S, and $|a_n|\leq n\sqrt{7/6}$ is a necessary condition (see Fitzgerald). Similarly, if $\sum^\infty_1|a_n|<\infty$, then $f(z)$ is continuous in $\overline{\mathbb{D}}$, and so belongs to H^p for every positive p and to N, whilst if $f\in N$, then $|a_n|\leq\exp(cn^\frac{1}{2})$ for some constant c. Again, if $f(z)$ belongs to one of the above classes, then so does $\frac{1}{t}f(tz)$ for $0 < t < 1$, so that the sequence (t^{n-1}) is a multiplier sequence. In other cases, negative results are known. Thus Frostman showed that (n) is not a multiplier sequence from N to N, and Duren showed that $\big(\frac{1}{n+1}\big)$ is not such a sequence either. (P. L. Duren, except for (e) which is due to A. Shields)

(The corona conjecture) Let D be an arbitrary domain in the plane that supports non-constant bounded analytic functions. Suppose that $f_1(z),\ldots, f_n(z)$ are bounded and analytic in D and satisfy \[\sum^n_{\nu=1}|f_\nu(z)|\geq\delta>0\] in D. Can one find bounded analytic functions $g_\nu(z)$ in D such that \[\sum^n_{\nu=1}f_\nu(z)g_\nu(z)\equiv1\] in D? When D is a disc, Carleson proved that the answer is `yes', and the result extends to finitely connected domains. The result is also known to be true for certain infinitely connected domains (see Behrens , Gamelin), but false for general Riemann surfaces of infinite genus (Cole, unpublished). Presumably the answer for the general plane domain is negative. Proofs of all positive results depend on Carleson's theorem. (L. Zalcman)

Suppose that $f(z)$ is a function as in ([source label: B5.13]) and define \[\mu=\limsup_{r\to1}\frac{\log\log M(r,f)}{-\log(1-r)},\] where $M(r,f)$ is the maximum modulus of $f(z)$ on $|z| = r$. We do not now assume ([source label: B5.12]), but let $N^0(t)$ be the number of n_k not greater than t. If $N(r, a)$ is the function of Nevanlinna theory (see Chapter 1) it is known that \[\limsup_{r\to1}\frac{N(r,0)}{\log M(r,f)}=1\] provided that either [(a)] ; $\mu > 0$ and \[\liminf_{k\to\infty}\frac{\log(n_{k+1}-n_k)}{\log n_k}>\frac{1}{2}\Big(\frac{2+\mu}{1+\mu}\Big),\] (this is implicit in Wiman, see Sunyer and Balaguer), or ; $\mu>\frac{1-\beta}{\beta}$ and $N^0(t)=O(t^{1-\beta})$ as $t\to\infty$, where $0<\beta<1$, see Sons . If $0<\mu<\frac{1-\beta}{\beta}$ with $N^0(t)=O(t^{1-\beta})$ as $t\to\infty$ we ask $(a), (b)$ and (c) of the preceding problem, at least for those cases not covered above. In particular we may consider the cases $n_k = [k^\alpha]$, where $1 < \alpha < \frac{3}{2}$. (L. R. Sons)

Tao-Shing Shah has shown that if $g(z)\prec f(z)$ in $\mathbb{D}$, $g'(0)/f'(0)$ is real, and f in S then $$ |g(z)|\leq|f(z)|\text{ for }|z|\leq\frac{1}{2}(3-\sqrt{5}), $$ $$ |g'(z)|\leq|f'(z)|\text{ for }|z|\leq3-\sqrt{8}. $$ Both constants are `best-possible'. Shah's proofs are technically very involved and it would be nice to have simpler proofs. Goluzin gave simpler proofs but with worse constants in each case. His methods appear to be incapable of yielding ([source label: C5.1]) and ([source label: C5.2]). (P. L. Duren)

Goluzin has shown that, if $g(z)\prec f(z)$ in $\mathbb{D}$, then \[M_2(r,g')\leq M_2(r,f'),\hspace{1cm}0\leq r\leq\frac{1}{2}.\] Here, for $p > 0$, \[M_p(r,h)=\Big(\frac{1}{2\pi}\int^{2\pi}_0|h(re^{i\theta})|^p\,d\theta\Big)^{1/p}.\] The result is not necessarily true if $r > \frac{1}{2}$, as $f(z) = z, g(z) = z^2$ shows, though it follows from a theorem of Littlewood that, for all p, \[M_p(r,g)\leq M_p(r,f),\hspace{1cm} 0 < r < 1.\] Find the largest number $r_p, 0 < r_p < 1$, independent of f and g so that \[M_p(r,g')\leq M_p(r,f'),\hspace{1cm} 0<r<r_p,\] if $g\prec f$. Note: If $g(z) \prec f(z)$ in $\mathbb{D}$, then $g(z) = f(\phi(z))$ so that \[|g'(z)|\leq |f'(\phi(z))|,\hspace{1cm}|z|\leq\sqrt{2}-1,\] (see Carath\'eodory). Thus if $h(z) = f'(\phi(z))$ then $h\prec f'$ so that, by Littlewood's theorem, $M_p(r,g') \leq M_p(r,h) \leq M_p(r,f')$ for $p > 0, r \leq\sqrt{2}-1$. This improves what one gets if one applied ([source label: C5.2]) to the p-th means since $\sqrt{2}-1>3-\sqrt{8}$; but it may not be best possible. (P. L. Duren)

If A is any analytic subset of the Riemann sphere it was shown by Kierst that A is (exactly) the set of asymptotic values of a function meromorphic in $\mathbb{D}$. If $\infty\in A$, Kierst also proved that A is the set of asymptotic values of a function f analytic in $\mathbb{D}$. However, there exist analytic sets which are not the set of asymptotic values of a function analytic in $\mathbb{D}$. Ryan has characterised those subsets of the Riemann sphere which are the set of asymptotic values of a function analytic in $\mathbb{D}$. Can one find a simpler characterisation? (K. F. Barth)

Suppose that f is analytic in $\mathbb{D}$. Plessner's theorem asserts that at almost all points $e^{i\theta}$ on the unit circle, either f has an angular limit, or else the image $f(S)$ of every Stolz angle S with vertex at $e^{i\theta}$ is dense in $\mathbb{C}$. How much can `dense' be improved? In particular, is it true that at almost all $e^{i\theta}$ either f has an angular limit, or else $f(S)$ is all of $\mathbb{C}$, except perhaps for a set of zero logarithmic capacity? This result would be best possible, since if E is any closed set of capacity zero then the universal covering map of the disc onto $\mathbb{C} \setminus E$ has angular limits almost nowhere. (A. Baernstein II)

(Subordination and extreme point problem) Let $g(z)=\sum^\infty_{n=0}B_nz^n$ be analytic in $\mathbb{D}$. Denote by S_g the family of functions $f(z)$ subordinate to g. Find general conditions on g so that the only extreme points of the closed convex hull of S_g are the functions $g(ze^{it})(0\leq t<2\pi)$. This is known for certain functions g, see Clunie , for example: [(a)] ; $g(z)=[(1+cz)/(1-z)]^\alpha$ where $|c|\leq1,\alpha\geq1$; ; $g(z)=\exp[(1+z)/(1-z)]$. Sheil-Small can prove it for a functions of the form \linebreak\mbox{$g(z)=h((1+z)/(1-z))$}, where $h(w)$ is a univalent quadratic polynomial in $\text{Re}\, w>0$. One might expect that the conclusion would hold for a functions g with positive coefficients increasing in a suitably regular manner. (T. Sheil-Small)

Let the function f have the power series $f(z)=\sum^\infty_{n=0}a_nz^n$ of radius of convergence 1; let E be the singular set on $\mathbb{T}$, and suppose that \[\sup_{\xi\in E}\, \sup_{N\geq0}\Big|\sum^N_{n=0}a_n\xi\Big|<\infty.\] It has been shown by Allan, O'Farrell and Ransford that, if E has measure zero, then $\sum^\infty_{n=0}a_nz^n$ converges to $f(z)$ at each point z in $\mathbb{T}\setminus E$. Does the conclusion remain true if E has positive measure? (Nothing appears to be known either way.) (T. J. Ransford)

In general, the radial behaviour of the derivative of a bounded analytic function in $\mathbb{D}$ can be pretty arbitrary; in fact, even under much stronger restrictions than just bounded, it can still be quite arbitrary. Is it true that, given any measurable function $m(\theta)$ on $[0,2\pi)$, there exists a function $f(z)$, continuous on $\overline{\mathbb{D}}$ and univalent on $\mathbb{D}$, such that \[\lim_{r\to1}f'(re^{i\theta})=m(\theta)\] for almost all θ? (In terms of known results, the conjecture seems quite plausible. Ortel and Schneider showed that the conjecture is true under slightly strengthened hypotheses; and Lohwater, Piranian and Rudin showed that the conjecture is true with a slightly weakened conclusion.) [(a)] ; Let f be a non-constant analytic function in $\mathbb{D}$, m be a positive integer, and define $\psi = (f)^mf'$. Then it is shown by Sons () that, when f and ψ both belong to MacLane's class A , either [(i)] ; f has finite asymptotic values on a dense subset of $\mathbb{T}$, or ; ψ assumes every finite value infinitely often. What replacements can be found for (i) (to give another correct theorem)? Can ψ be taken to be of the form
\[\psi=(f)^{m_0}(f')^{m_1}\ldots(f^{(k)})^{m_k},\]
whenever $k,m_0,m_1,\ldots,m_k\in\mathbb{N}\cup\{0\}$? ; It is known that the conclusion in part (a) is true when ψ is replaced by
\[\psi=f^{(l)}+\sum^{i-1}_{\nu=0}a_\nu f^{(\nu)},\]
where $l\in\mathbb{N}$ and the a_ν are analytic functions in $\{|z| < 1 +r\}$, for some positive r. What replacements can be found in this case for (i) to give another correct theorem? Can the a_ν be taken as functions analytic in $\mathbb{D}$ with $T(r,a_\nu) = o(T(r,f))$ as $r\to1$? (For both parts, compare Problem 1.38.) (L. R. Sons)

Let J be a Jordan curve in $\mathbb{C}$ bounding a domain D. Suppose that $f:e^{it}\mapsto f(e^{it})$ is a sense-preserving homeomorphism of the unit cirlce $\mathbb{T}$ onto J, and that the harmonic extension of f to $\mathbb{D}$ satisfies the relation $f(\mathbb{D})\subset D$. Prove that f is a homeomorphism of $\mathbb{D}$ onto D. This is known to be true if J is convex, when the hypothesis $f(\mathbb{D})\subset D$ is automatically satisfied because of the positivity of the Poisson kernel by the Kneser-Rado-Choquet theorem, see Duren . The result is also known to be true when $\partial f/\partial t$ is continuous and non-zero (on $\mathbb{T}$), and when the co-analytic and analytic parts of f have continuous derivatives on $\overline{\mathbb{D}}$. (T. Sheil-Small)

Let f be analytic univalent in $\mathbb{D}$, and consider \[I_\lambda(r,f')=\Big(\frac{1}{2\pi}\int^{2\pi}_0\big|f'(re^{i\theta})\big|^\lambda\,d\theta\Big)^{1/\lambda}\] where $\lambda > 0$. ; What is the maximal order of magnitude of $I_\lambda(r,f')$ as $r\to1$, where $0\leq \lambda\leq\frac{2}{5}$? If $\lambda>\frac{2}{5}$, it is known that $I_\lambda(r,f') = O\big(1/(1-r)^{3-1/\lambda}\big)$ with equality when f is the Koebe function. The case $\lambda >\frac{1}{2}$ follows easily from classical facts, while the case $\frac{2}{5}\leq \lambda \leq\frac{1}{2}$ is due to Feng and MacGregor . (It was formerly conjectured that the Koebe function would still be extremal for $\lambda>\frac{1}{3}$; but an example of Makarov has shown that this is not the case for $\lambda\leq\frac{1}{3}+\varepsilon$, for some positive ε.) ; Now normalise the function f to belong to the usual class S. For $\lambda>\frac{2}{5}$, we know that \[I_\lambda(r,f')\leq C_\lambda I_\lambda(r,k'),\] where k is the Koebe function. For which λ is the best constant C_λ equal to 1? (It follows from de Branges' theorem that $C_\lambda = 1$ for \mbox{$\lambda = 2,4,6,\ldots$}. Presumably $C_\lambda=1$ for $\lambda\geq2$, but the proposer knows of no proof of this.) (A. Baernstein)

Let Ω be a simply-connected domain in the finite plane whose complement contains n disjoint closed balls with centres on the interval $[0,1]$ and common radius ε, $\varepsilon<1/n$, (such domains are the so-called `ball and chain domains'). Let z_0 in Ω be a point at a distance at least 1 from each ball, and let $w(z_0,\Omega)$ denote the harmonic measure at z_0 of the union of the balls, relative to Ω. Is it true that, for every positive δ, there is an estimate $$ w(z_0,\Omega)\leq C_\delta(n\varepsilon)^{\frac{1}{2}-\delta}, $$ where C_δ depends only on δ. An affirmative answer would imply the L^p extension, for $1 < p < 2$, of the Hayman-Wu theorem mentioned in Problem 6.93. In the case $n = 1$, the Beurling-Nevanlinna projection theorem shows that ([source label: J1.110]) is true with exponent $\frac{1}{2}$; however, for large n there are examples that show that this is then false. Let A denote the class of functions $f(z) = z + a_2z^2 +\ldots$ analytic in $\mathbb{D}$. For $\delta\geq0$ and $T= \{T_k\}^\infty_2$ a sequence of non-negative real numbers, define a T-δ-neighbourhood of $f\in A$ by \[TN_\delta(f)=\Big\{g:g(z)=z+b_2z^2+\ldots\in A,\sum^\infty_{k=2}T_k|a_k-b_k|\leq\delta\Big\}.\] When $T = \{k\}^\infty_2$, we call $TN_\delta(f) = N_\delta(f)$ a δ-neighbourhood of f (δ-neighbourhoods were introduced by Ruscheweyh , who used them to generalise the result that $N_1(z)\subset St$, the class of normalised star-like functions in $\mathbb{D}$.) Now let $K[A,B]$ denote the class of univalent functions \[\{f:f\in S,1+zf''(z)/f'(z)\prec(1+Az)/(1+Bz),z\in \mathbb{D}\},\] where $-1\leq B<A\leq1$, introduced by Janowski . See also Pommerenke for discussion on $\prec$ and subordination. The proposers have shown that if $f\in K[A,B]$, and either \[(a)\hspace{1cm}-\frac{1}{4}(\sqrt{3}+2)\leq B<A\leq1\hspace{1cm}\text{ or }\hspace{1cm} (b)\hspace{1cm} -1\leq-A\leq B<A\leq1,\] then $N_\delta(f)\subset St$, where \[\delta= \begin{cases} (1-B)^{(A-B)/B},&\hspace{1cm} B\neq0, \\ e^{-A},&\hspace{1cm} B=0, \end{cases}\] and that this value of δ is best possible. Is this conclusion still valid without the hypotheses (a) and (b)? (T. Sheil-Small and E. M. Silvia)

If f in A and $\delta > 0$, define a $\Sigma_\delta(f)$ neighbourhood of f to be \[\Big\{g:g\in A,\big|(g'(z)-f'(z))-\frac{1}{z}(g(z)-f(z))\big|+\big|(g'(z)-f'(z))+\frac{1}{z}|g(z)-f(z))\big|<2\delta\Big\}.\] Clearly, $N_\delta(f)\subset\sum_\delta(f)$. Then it is known by Sheil-Small and Silvia that $\sum_1(z)\subset St$, and \mbox{$\sum_\frac{1}{4}(f)\subset St$} for convex functions f, with the notation in Problem 6.111. Given a normal family $\mathcal{F}$ in A, the dual, $\mathcal{F}^*$, of $\mathcal{F}$ is the set \[\big\{f:f\in A,f\ast g\neq0\text{ for all }g\in\mathcal{F},0<|z|<1\big\},\] where $\ast$ denotes the Hadamard product, see Ruscheweyh . The Bieberbach conjecture (see de Branges) is equivalent to the statement that $N_1(z)\subset S^*$ (where S^* is the dual of S). It seems reasonable therefore to ask whether $\sum_1(z)\subset S^*$. (Recall that $S^*\subset St$, see Ruscheweyh .) (T. Sheil-Small and E. M. Silvia)

Let G be a domain in $\mathbb{C}$ that contains the origin 0 and is axially-symmetric with respect to the real axis, that is, if a point $z\in G$ then the line segment with endpoints z and $\bar{z}$ also lies in G. (In particular it follows that G is simply-connected.) For $t>0$, let G_t and G_t' be the components of the domains \[\{z:z\in G,\text{Im }z< t\}\hspace{1cm}\text{ and }\hspace{1cm}\{z:z\in G,\text{Re }z< t\}\] containing 0. Let ω_t and ω_t' denote the harmonic measure at 0 of the sets \[\partial G_t\cap\{\text{Im }z=t\}\hspace{1cm}\text{ and }\hspace{1cm}\partial G_t'\cap\{\text{Re }z=t\}\] with respect to the domains G_t and G_t' respectively. Now let D_1 and D_2 be two domains in $\mathbb{C}$ of this type, and use for each the notation just described. Then: [(a)] ; If $\omega_t(D_1)\equiv \omega_t(D_2)$ for each $t>0$, is it true that $D_1 = D_2$? ; If $\omega_t'(D_1)\equiv \omega_t'(D_2)$ for each $t>0$, is it true that $D_1 = D_2$? ; If both (a) and (b) fail, is it true that $D_1 = D_2$ if $\omega_t(D_1)\equiv \omega_t(D_2)$ for each $t>0$ and $\omega_t'(D_1)\equiv \omega_t'(D_2)$ for each $t>0$? If the answer to (a) or (b) is `yes', in that case, how few $t$'s does one need for the conclusion to hold? (For example, infinitely many $t$'s such that $\{\text{Im }z = t\}$ or $\{\text{Re }z = t\}$ meet the domains? Or do the $t$'s need to be dense?) If the answer to $(a)$, $(b)$ or $(c)$ is `yes', in that case can one replace `axially-symmetric' by `simply-connected', or perhaps drop this requirement completely? (D. A. Brannan)

Suppose that $f(z)$ in S, and that positive integers $k, m, n,$ are given. It is known that there exist complex numbers $c_0, c_1,\ldots,c_m,$ depending on k, m, n and f, such that $c_0=1$, $|c_m|\geq4^{-m}$ and $$ |c_0a_{n+j}+c_1a_{n+j+1}+\ldots+c_ma_{n+j+m}|\leq Kn^{\alpha_m},\hspace{1cm}0\leq j\leq k, $$ where K is a constant depending on k, m and f, and $\alpha_m=8/\sqrt{m-\frac{1}{2}}$. What are the best possible values for the α_m? See Pommerenke . It is known that $\alpha_1=0$, and it may be conjectured that $\alpha_2=-\frac{1}{3}$, $\alpha_3=-\frac{1}{2}+\varepsilon$, and $\alpha_m<-\frac{1}{2}$ for $m>4$. If, in addition, $f(z)$ is star-like, then Pommerenke has shown that ([source label: 6.5]) holds with $\alpha_m=-1+\frac{2}{m+1}$. The result is sharp.

The results of Pommerenke were proved in fact for mean p-valent functions, and if $f(z)=\sum^\infty_{n=0}a_nz^n$ is mean p-valent with $p>\frac{1}{4}$, then ([source label: 6.5]) holds with $\alpha_m=-\frac{1}{2}+8p^\frac{3}{2}/\sqrt{m}$. This result is probably far from the best possible, though clearly $\alpha_m\geq-\frac{1}{2}$ in all cases. Lucas has shown that $\alpha_1=2p-2$ if $p\geq1$, and $\alpha_1\leq 2p-2\sqrt{p}$ for $\frac{1}{4}<p<1$. It is fair to conjecture that the correct value of α_1 is $p-1$ for $\frac{1}{2}<p<1$ and $-\frac{1}{2}$ if $p<\frac{1}{2}$. It might also be conjectured that $\alpha_m=-\frac{1}{2}$ for $m+1>4p$. The functions \[f(z)=\Big(\frac{1+z^{m+1}}{1-z^{m+1}}\Big)^{2p/(m+1)}=1+\sum^\infty_{n=2}a_nz^n\] provide counter-examples. These functions are mean p-valent, and $a_n=0$ except when $(m+1)$ divides n, and for the remaining values of n we have, as $n\to\infty$, \[|a_n|\sim Cn^{2p/(m+1)-1},\hspace{1cm}\text{ where }C\text{ is a constant}.\] Thus ([source label: 6.5]) cannot hold with $\alpha_m<2p/(m+1)-1$.

A related problem concerns upper bounds for $|a_{n+1}|-|a_n|$ when $f(z)$ is mean p-valent. Lucas has proved that \[\big||a_{n+1}|-|a_n|\big|=O(n^{j_d}),\] where $j_d=2p-2$, if $p\geq1$; $j_d\leq2p-2\sqrt{p}$ if $\frac{1}{4}<p<1$; and $j_d=-\frac{1}{2}$, if $p<\frac{1}{4}$. The result for $\frac{1}{4}<p<1$ is probably not sharp. A similar question may be asked for symmetric mean p-valent functions of the type \[f(z)=\sum^\infty_{n=0}a_nz^{an+b}.\] The coefficients of such functions behave rather like those of functions $\sum a_nz^n$ which are mean (p/a)-valent. In particular, if $f(z)=z+\sum a_nz^{2n+1}$ is mean univalent, then Lucas proved that \[\big||a_{n+1}|-|a_n|\big|=O(n^{1-\sqrt{2}}).\]

Research Problems in Function Theory - Problem 6.25

O / open | AMR 问题清单汇编

Suppose that p is an integer and $f(z)=\sum^\infty_{n=0}a_nz^n$ is p-valent in $\mathbb{D}$. It is conjectured by Goodman that \[|a_n|\leq\sum^p_{k=1}|a_k|D(p,k,n),\] where \[D(p,k,n)=\frac{2kn\prod^p_{\alpha=1}(n^2-\alpha^2)}{(p+k)!(p-k)!(n^2-k^2)},\hspace{1cm}1\leq k\leq p<n.\] This result, containing the Bieberbach conjecture as a special case, is likely to be extremely difficult. The inequality if true would be sharp in all cases. No counter-examples are known and the conjecture has been proved only if $a_k=0$ for $k=1, 2, \ldots, (p-1)$ and $n=p+1$, see Spencer ; or $n=p+2$, see Jenkins . The conjecture is true and sharp for certain classes of p-valent functions, namely those which are typically real of order p, see Goodman and Robertson . We recall that the conjecture is definitely false for areally mean p-valent functions, if $p=1$ and $n=3$ by the example of Spencer , though for circumferentially mean p-valent functions it remains true in this case, see Jenkins .

Research Problems in Function Theory - Problem 6.26

P / partially_solved | AMR 问题清单汇编

Suppose that $f(z)=\sum^\infty_{n=0}a_nz^n$ is circumferentially mean p-valent and $f(z)\neq0$ in $\mathbb{D}$. (This latter condition is a consequence of mean p-valency if $p<1$). It is conjectured that in this case, at least if $p\geq 1$, we have $$ |a_n|\leq A_{n,p} $$ where $$ F(z)=a_0\Big(\frac{1+z}{1-z}\Big)^{2p}=\sum^\infty_{n=0}A_{n,p}z^{2n}. $$ The conjecture ([source label: 6.10]) is known to be true for $n=1$ and all p; and for $n=2, 3$ if $p=1$, by the results quoted in Problem 6.25. It is certainly false for small positive p, and large n, since it would imply $a_n=O(n^{\varepsilon-1})$ for every positive ε as $n\to\infty$, for a bounded univalent function. For if $g(z)$ is bounded and univalent, and $\varepsilon>0$, then if K is a sufficiently large positive constant $g(z)+K$ is circumferentially mean ε-valent. On the other hand, if $p>\frac{1}{4}$ and $f(z)$ is fixed, ([source label: 6.10]) holds for all sufficiently large n, see Hayman . In the special case when $p=1$ and $f(z)$ is univalent, ([source label: 6.10]) reduces to the Littlewood conjecture $|a_n|\leq4|a_0|n$. This conjecture is somewhat weaker than the Bieberbach conjecture. It was shown by Nehari (see also Bombieri) that we have at any rate $|a_n|\leq 4K_0|a_0|n$ if $f(z)$ is univalent, where K_0 is the constant of Problem 6.2. Thus, Littlewood's conjecture holds since $K_0=1$, as was pointed out in Update 6.2. It also seems likely that for $\lambda p>1$ \[I_\lambda(r,f)\leq I_\lambda(r,F)\] if $f(z)$ satisfies the above hypotheses, and $F(z)$ is given by ([source label: 6.11]).

Suppose f in S and define $h(z) = \{f(z^2)\}^{\frac{1}{2}} = z + c_3z^3 + c_5z^5 +\ldots$ Robertson's conjecture (see Sheil-Small) asserts that \[1+|c_3|^2+|c_5|^2+\ldots+|c_{2n-1}|^2\leq n.\] This is known to be true if f is star-like; is it true if f has real coefficients, or if f is close-to-convex? (P. L. Duren)

If $f(z)$ in S and if the a_n are real, then $$ 1+a_3+\ldots+a_{2n-1}\geq a_n^2,\hspace{1cm}n\geq1. $$ The Bieberbach conjecture for such functions follows easily, see e.g. Fitzgerald . It was pointed out by Clunie and Robertson that ([source label: C6.2]) holds for normalised typically-real functions; the inequality is clear from the representation formula for these functions. The Bieberbach conjecture for S would follow analogously if we could prove that if f in S, $$ 1+|a_3|+\ldots+|a_{2n-1}|\geq|a_n|^2,\hspace{1cm}n\geq1. $$ Bshouty (unpublished) has shown that if f in S, then there exists an $N(f)$ such that ([source label: C6.3]) holds for $n > N(f)$. Research Problems in Function Theory - Problem 6.42

S / solved | AMR 问题清单汇编

If f in S, write \[\log[f(z)/z]=2\sum^\infty_{k=1}\gamma_kz^k.\] If f is star-like then $|\gamma_k| \leq1/k$; this is false in general, even in order of magnitude. Milin (see) has shown that \[\sum^n_{k=1}k|\gamma_k|^2\leq\sum^n_{k=1}\frac{1}{k}+\delta\] where $\delta<0.312$, and that δ cannot be reduced to 0; Milin conjectured that $$ \sum^N_{n=1}\sum^n_{k=1}k|\gamma_k|^2\leq\sum^N_{n=1}\sum^n_{k=1}\frac{1}{k}, $$ which would imply Robertson's conjecture (see Problem 6.39). Inequality ([source label: C6.4]) is known to be true for $N = 1, 2, 3$ (see Grin\v span). Is it true in general if f has real coefficients, or if f is close-to-convex? (P. L. Duren)

If f is univalent analytic in $\mathbb{D}$, then it is well known (see Pommerenke) that both f and its first derivative f' must be normal, while the higher derivatives $f^{(n)}$ need not be normal if $n\geq2$. Setting $f^{(-1)}(z)=\int^z_0f(t)\,dt$ and $f^{(-n-1)}(z)=\int^z_0f^{(-n)}(t)\,dt$, it is easy to verify that $f^{(-2)}$ is Bloch; while if $n\geq3$, $f^{(-n)}$ is bounded (hence Bloch, and therefore normal). Thus, if f is univalent analytic in $\mathbb{D}$, then the functions $f^{(n)}$ must be normal for $n=1, 0, -2, -3,\ldots,$ and need not be normal for $n=2, 3, \ldots$. Must $f^{(-1)}(z)=\int^z_0f(t)\,dt$ be normal if $f(z)$ is univalent analytic in $\mathbb{D}$? (D. Campbell)

If $f(z)$ in S, write \[\log\frac{f(z)}{z}=2\sum^\infty_{n=1}\gamma_nz^n\] and \[f(z^p)^{1/p}=z+\sum^\infty_{n=1}c^{(p)}_nz^{pn+1}\hspace{1cm}(p=1,2,\ldots).\] Szeg\"o's conjecture asserts that $c^{(p)}_n=O(n^{2/p-1})$ as $n\to\infty$. This has been proved for $p = 1,2$ and 3, but Pommerenke has shown that it is false for $p\geq 12$; his example also has $\gamma_n\neq O(1/n)$. Milin has shown that, if a function f in S has the property that $\gamma_n=O(1/n)$, then $c^{(p)}_n=O(n^{2/p-1})$ for every p. Is the converse true? (P. L. Duren)

Let the function $f = z + a_2z^2 + \ldots$ in S map $\mathbb{D}$ onto a domain with finite area A. Then Bieberbach's inequality $|a_2|\leq2$ can be sharpened to the following: $$ |a_2|\leq2-cA^{-1/2} $$ where c is an absolute constant. What is the best value of c? Aharonov and Shapiro have shown that ([source label: J6.88]) holds for some c, and have a conjecture concerning the sharp constant c and the extremal function for ([source label: J6.88]). They also conjecture that $|a_2|\leq 2-c_1l^{-1}$, where l is the length of $\partial f(\mathbb{D})$. For some background information see Aharonov and Shapiro (and) and Abarov, Shapiro and Solynin (and). (H. S. Shapiro)

Let $S^*(\frac{1}{2})$ denote the class of functions g analytic in $\mathbb{D}$ and such that $\text{Re}\, (zg'/g) > \frac{1}{2}$ in $\mathbb{D}$. Is it true that, if $f\in S^*(\frac{1}{2})$, $r\in (0,1)$ and $\theta\in[0,2\pi)$, then $$ \frac{1}{|f(re^{-i\theta})|}\int^r_0|f'(te^{i\theta})|\,dt\leq\frac{\arcsin r}{r}? $$ (The left-hand-side of ([source label: J6.89]) is the ratio of the length of the image of a radius and the distance between the endpoints of that image (as the crow flies).) Inequality ([source label: J6.89]) is true when $f(z) = z/(1-z)$; in addition, the left-hand-side of ([source label: J6.89]) never exceeds $\pi/2$ for any r or f. Let z_1,z_2 lie in $\mathbb{D}$. Then, in the smaller class of convex functions f, what can be said about \[\frac{1}{|f(z_1)-f(z_2)|}\int^{z_2}_{z_1}|f'(t)|\,|dt|?\] (R. R. Hall)

Let Ω be an arbitrary domain in $\mathbb{C}$. Does there necessarily exist a set E in $\partial\Omega$, of full harmonic measure, with the following property: for each z in E, there exist circular arcs C_r in Ω, of radius r (where r is small) and centred at z, for which \[\lim_{R\to0}\Big(\frac{1}{\pi R^2}\int^R_0\theta(C_r)r\,dr\Big)=\frac{1}{2},\] where $\theta(\,\cdot\,)$ denotes angular measure? For simply-connected domains Ω, this is a theorem of McMillan . For general domains Ω, at least there is a sequence $\{r_n\}$ decreasing to 0 for which $\theta(C_{r_n})$ approaches $\pi/4$. (D. Stegenga and K. Stephenson)

If $\mathbb{R}^2_+=\{(x,y)\in\mathbb{R}^2:y>0\}$, suppose that $E\subset\mathbb{R}^2_+$, and let $f:\mathbb{R}^2_+\to B^2$ be analytic and conformal where $B^2 = \{(x, y)\in\mathbb{R}^2_+: x^2 + y^2 < 1\}$; assume also that \[\lim_{x\to0,\,x\in E}f(x)=\alpha.\] Lindel\"of's theorem shows that α is an angular limit of f at 0 if E is a curve terminating at 0. Vuorinen has shown that the same conclusion holds under much weaker hypotheses on E; for instance, the condition that \[\liminf_{r\to0}m(A\cap(0,r))/r>0,\] where $A = \{|x|: x \in E\}$, is sufficient (see Vuorinen). This problem concerns a converse result. Denote by $\mathcal{F}$ the class of all analytic and conformal maps of $\mathbb{R}^2_+$ into B^2. Let K be a subset of $\mathbb{R}^2_+$ with the property that, whenever \[\lim_{x\to0,\,x\in E}f(x)=\alpha\hspace{1cm}\text{ and }\hspace{1cm}f\in\mathcal{F},\] then necessarily f has an angular limit α at 0. Since f is conformal it follows (see Vuorinen) that \[\lim_{x\to0,\,x\in K_1}f(x)=\alpha,\] where $K_1 = \{(x,y)\in\mathbb{R}^2_+ : \rho((x,y), K) < l\}$ and ρ is the Poincar\'e metric of $\mathbb{R}^2_+$. What can be said about the thickness of K_1 at 0? Is it true that $$ \limsup_{r\to0}m\big(B^\prime\cap(0,r)\big)/r>0, $$ where $B^\prime = \{(x^2 + y^2)^{1/2} : (x,y)\in K_1\}$? It is easy to see that ([source label: J6.92]) must hold if K is contained in an angle with vertex at 0 whose closure lies inside $\mathbb{R}^2_+$. (M. Vuorinen)

Goodman conjectured that if $f(z) = \sum^\infty_{n=1}a_nz^n$ is p-valent in $\mathbb{D}$, then for each $n> p$, we have \[|a_n|\leq\sum^p_{k=1}\frac{2k(n+p)!}{(p+k)!(p-k)!(n-p-1)!(n^2-k^2)}|a_k|.\] If the bound is true, then it is sharp in all of the variables p, n, $a_1,\ldots, a_p$. The conjecture has been proved for large subclasses (, ,), but is still open in general. The simplest case, namely for all 2-valent functions, is still open; but Watson has made important contributions towards proving this inequality. (A. W. Goodman)

The coefficients of a p-valent function are bounded by some function of its zeros. In particular, let the function \[f(z)=z^q+\sum^\infty_{n=q+1}a_nz^n\] be p-valent in $\mathbb{D}$ and have s zeros β_k, $k= 1,2, \ldots, s$, where $0 < |\beta_k|<1$. Goodman conjectured that, under these hypotheses, $|a_n|\leq |A_n|$ where A_n is defined by the identity \[F(z)=\frac{z^q}{(1-z)^{2q+2s}}\Big(\frac{1+z}{1-z}\Big)^{2t}\prod^s_{k=1}\Big(1+\frac{z}{|\beta_k|}\Big)\big(1+|\beta_k|z\big)=z+\sum^\infty_{n=2}A_nz^n,\] where $t = p-q-s\geq0$. The conjecture has been proved if $t = 0$ and $f(z)$ is p-valent star-like with respect to the origin . However, it is still open in general. (A. W. Goodman)

One part of Nevanlinna theory is devoted to the following problem. How does the geometric structure of a simply connected Riemann covering surface of the sphere influence the value distribution of the meromorphic function generating the surface? It is suggested that one also consider halfsheets among the constituent pieces of such surfaces, which have an infinite number of branch points on their boundary. A typical example is the covering surface generated by $e^z - z$. It contains a right half-plane with a second order branch point at $2\pi in$ for each integer n. (F. Huckeman)

Let D be a domain in the extended complex plane. A finite point z on the boundary ∂D of D is called angular (relative to D) if there exists $\varepsilon > 0$ such that every component domain of $D\cap\{|z - z_0| < \varepsilon\}$ which has z_0 as a boundary point, is contained in an angle less than π with vertex at z_0. Angularity at ∞ is similarly defined. Let $A = A(D)$ be the set of angular points of ∂D relative to D. Obviously A not empty implies that ∂D has positive capacity. The set $A(D)$ can have positive linear measure. E.g. let C be a Cantor set on $|z|=1$ and let D consist of the open unit disc from which have been deleted all points rz with $z \in C$ and $\frac{1}{2}\leq r < 1$. Then $A(D) = C$ which can, of course, have positive linear measure. Yet the following holds for arbitrary domains: $A(D)$ is either empty or its harmonic measure, relative to any point of D, is zero. This result follows easily from an unpublished theorem on Brownian paths $\omega(t)$ in the complex plane. This says that almost all such paths have the property that for every real t_0 and every $\varepsilon > 0$ the set of numbers $\Big|\frac{\omega(t)-\omega(t_0)}{\omega(t)-\omega(t_0)}\Big|$ with $t_0<t<t_0+\varepsilon$ fills at least an open arc of length π on the unit circle. This theorem is not easy and it would be desirable to give a direct proof of the above result on $A(D)$. Moreover, the Brownian paths approach will certainly not yield a similar result for the set $B_\alpha(D)$ of ∂D whose points are defined by replacing the angles less than π with translates of $\{x+iy : 0<x< |y|^\alpha\}$ for a given α with $\frac{1}{2}< \alpha < 1$. (For $\alpha=\frac{1}{2}$ the result is false as can be seen by taking D to be a disc.) Problem: For which $\alpha\in(\frac{1}{2},1)$ is the harmonic measure of the set $B_\alpha(D)$ always zero? (Of course we may assume that the capacity of ∂D is positive.) A much more difficult problem would be to characterise the monotone functions $f(y)$ having the property that the set obtained on replacing the angles by translates of $\{x+iy : 0 < x < f(|y|)\}$ has necessarily harmonic measure zero. Similar questions can be asked for Riemann surfaces and for n-dimensional space. (A. Dvoretzky)

Let K be a compact set of positive measure in $\mathbb{C}$. Does there necessarily exist a non-constant analytic function in $\mathbb{C}\setminus K$ with $f(\infty) = 0$ such that $[f(z)-f(\zeta)]/[z-\zeta]\neq\pm1$ for any $z, \zeta\in\mathbb{C}\setminus K$? Conceivably, the hypotheses even imply the existence of non-linear analytic functions f with $|f(z) -f(\zeta)| / |z - \zeta|$ bounded, but this is a well-known unsolved problem. Of course one can pose more general problems again such as requiring that the difference quotient omit all values in some pre-assigned plane set. (These problems arise in the use of variational methods.) (D. Aharonov and H. S. Shapiro)

Is there a homeomorphism of the open unit ball in $\mathbb{R}^3$ onto $\mathbb{R}^3$, whose coordinate functions are harmonic? In other words, do there exist u_1,u_2,u_3 harmonic in $|x|<1$, $x = (x_1, x_2, x_3)$, such that \[(x_1, x_2, x_3)\to (u_1, u_2, u_3)\] is a homeomorphism of $|x| < 1$ onto all of $\mathbb{R}^3$? The analogous problem in $\mathbb{R}^2$ is answered negatively; the result is due to T. Rado (no citation), and is an important lemma in the theory of minimal surfaces. (H. S. Shapiro)

Let $P(\theta)=\sum^N_{n=1}e^{i\lambda_n\theta}$ be a finite Dirichlet series with exponents $\gamma_m\neq\gamma_n$ for $m\neq n$. What can be said about $\mu\equiv\inf|P(\theta)|$? A trivial argument shows that $\mu\leq (N-1)^{1/2}$. In fact, $|P|^2=N+2\sum_{m\neq n}\cos(\lambda_m-\lambda_n)\theta$. If $w(\theta)=|P|^2-N\geq-c$, then let $h(\theta)=c+w(\theta)=2\sum b_n\cos(\delta_n\theta)$, where the b_n are positive integers. Then \[b_n=\lim_{T\to\infty}\frac{1}{2T}\int^T_{-T}h(t)\cos(\delta_nt)\,dt\leq\lim_{T\to\infty}\frac{1}{2T}\int^T_{-T}h(t)\,dt=c.\] Thus $c\geq1$. The problem arises in prediction theory where $\mu\leq(N-1)^{1/2}$ is adequate. If the λ_n are rational, then the problem reduces to a problem on polynomials with coefficients 0 and 1. (S. Rudolfer and W. K. Hayman)

Let $\beta_j\in\mathbb{R}^+$ and $\zeta_j\in\mathbb{C}$, and for suitable small z define $$ f(z)=\prod^n_{j=1}(1-\zeta_jz)^{\beta_j}=1+a_1z+a_2z^2+\ldots $$ Suppose further that the a_k are all real. Then there exists $N=N(\beta_1, \beta_2, \beta_3, \ldots, \beta_n)<\infty$, independent of the ζ_j, such that $\min(a_1, a_2, \ldots, a_N)\leq0$. Find a sharp, or good, upper bound for N as a function of the β's. This would be significant for Tur\'an's power sum method. To see that $N<\infty$: if the β_j's are all integers, then f is a polynomial and $N=\beta_1+\beta_2+\beta_3+\ldots+\beta_n+1$. (The sort of estimate wanted in the general case.) If not, assume that $|\zeta_1|\leq|\zeta_2|\leq\ldots\leq|\zeta_n|\leq1$, and let $m=\max\{j:\beta_j\in\mathbb{Z}\}$. The radius of convergence of ([source label: 7.341]) is $|\zeta_m|^{-1}$ and if the a_k were all positive (or even greater than or equal to 0). then by Pringshein's theorem (see Titchmarsh), $|\zeta_m|^{-1}$ would be a singularity of f. Since f only has the singularities $\{\zeta^{-1}_j:\beta_j\notin\mathbb{Z}\}$ we deduce that $\zeta_m>0$. We multiply through by $(1-\zeta_m)^{-\beta_m}$ which has positive coefficients, and repeat the arguments. After at most n steps, we obtain a contradiction. This gives a finite N for any particular set of ζ_j and the uniformity is straightforward. (R. Hall)

This problem is equivalent to Problem 7.9 due to Gehring and Reich about best bounds for area distribution under quasiconformal mapping. Let E denote a measurable subset of the unit disc $\mathbb{D}$, m denote 2-dimensional measure, and define \[f_E(z)=-\frac{1}{\pi}\int\int_E\frac{dm(w)}{(w-z)^2},\hspace{1cm}z\in\mathbb{C}\setminus E.\] Thus, f_E is the 2-dimensional Hilbert transform of the characteristic function of E. It follows from the Calder\'on-Zygmund theory of singular integrals that there are constants a and b such that \[\int\int_{\mathbb{D}\setminus E}|f_E|\,dm\leq am(E)\log\frac{\pi}{m(E)}+bm(E)\] for every E. The problem is to find the smallest possible a (for which there exists some b such that the inequality holds for every $E\subset\mathbb{D}$). Consideration of $E=\{z:|z|<\delta\}$ for small δ shows that $a=1$ would be best possible, and this is conjectured by Gehring and Reich. An analogous sharp inequality for sets $E\subset[-1,1]$ and 1-dimensional Hilbert transforms \[f_E(x)=-\frac{1}{\pi}\int_E\frac{dt}{x-t}\] is known, and can be proved either by a subordination argument or by use of a theorem of Stein and Weiss. Define the Harnack function $H_{z_0}(z)$ for a Green domain D relative to $z_0\in D$ to be the supremum of all positive harmonic functions h on D to be the supremum of all positive harmonic functions h on D which satisfy $h(z_0)\leq1$. If $K_\zeta(z)$ is the Martin kernel for D relative to z_0, $K(\zeta_0)=1$ for all ζ in the Martin boundary Δ_1, then \[H_{z_0}(z)=\sup\{H_\zeta(z):z\in D, \zeta\in\Delta_1\}.\] In particular for D the unit disc, the boundary Δ_1 may be identified with the unit circle $\mathbb{T}$ and, if $z_0=0$, then $K_\zeta(z)$ is the Poisson kernel with pole at $\zeta\in T$. In this case, $K_\zeta=H_0$ along the radius to ζ. Using the Riemann mapping functions, this property may be described for simply connected D as follows: for each $\zeta\in \Delta_1$, K_ζ touches H_{z_0} along a Green line for D issuing from z_0. Does this property continue to hold for D multiply connected? (M. Arsove and G. Johnson)

It is known that any quasi-conformal homeomorphism of $B^n = \{x : x \in\mathbb{R}^n,|x|<1\}$ onto a Jordan domain D in $\mathbb{R}^n$ can be extended to a homeomorphism of B^n onto D. If ∂D is rectifiable (in the sense that $\Lambda^{n-1}(\partial D)<\infty$), is $f|_{\partial B^n}$ absolutely continuous (in the sense that $\Lambda^{n-1}\big(f(E)\big)=0$ for every set E in ∂B^n with $|E|=0$)? One can also ask the analogous question about f^{-1}. When $n = 2$, the answer to both questions is `yes' for conformal mappings, but `no' for quasi-conformal mappings. When $n = 3$, Gehring has proved that, if in addition the function f has a quasi-conformal extension to $\mathbb{R}^n$, then $f|_{\partial B^n}$ is absolutely continuous; but, even in this special case, it is not known if $f^{-1}|_{\partial D}$ is absolutely continuous. Let $\mathcal{W}$ be a hyperbolic Riemann surface, G_ω the Green's function with pole $\omega\in\mathcal{W}$, and $\Gamma=\{[\gamma_n]\}$ the fundamental group. Let $\tilde{\Gamma}$ be the subgroup of equivalence classes $[\gamma]$ such that, for every $\omega\in\mathcal{W}$, the harmonic conjugate G^*_ω of G_ω changes by an integral multiple of 2π on a representative path in $[\gamma]$. Certainly $[\Gamma,\Gamma]\triangleleft\tilde{\Gamma}\triangleleft\Gamma$. Is it true that, if $[\Gamma, \Gamma] \neq\tilde{\Gamma}$, then $\mathcal{W}$ is necessarily of the form $\mathcal{V}\setminus A$ where $\mathcal{V}$ is a hyperbolic surface and $A\neq\emptyset$ is a relatively closed subset of zero logarithmic capacity? The conjecture is true if $\tilde{\Gamma}=\Gamma$ and $\mathcal{V}$ is the unit disc; and it is false if $[\Gamma,\Gamma] = \tilde{\Gamma}$. (The conjecture arises from work in .) (K. Stephenson)

A continuous mapping $f:B^n\to\mathbb{R}^n$, where $B^n = \{x : x\in\mathbb{R}^n,|x|<1\}$, and $n\geq2$, is said to be proper if $f^{-1}(K)$ is a compact subset of B^n whenever K is a proper subset of $f(B^n)$. Let \[B_f = \{z : z \in B^n, f\text{ is not a local homeomorphism at }z\}.\] Is it true that, if [(i)] ; $n\geq3$, ; $f:B^n\to\mathbb{R}^n$ is proper and quasi-analytic, and [(iii)] ; B_f is compact then f is necessarily injective? Note that the mapping $f(z) = z^2$, where $z \in B^2$, shows that the conjecture is false when $n = 2$. The conjecture is known to be true in the special case that $f(B^n) = B^n$, $n\geq3$. The conjecture is a special case of a more general open problem in . (M. Vuorinen)

Let V be the zero set of some analytic function in a strictly pseudo-convex domain Ω in $\mathbb{C}^2$. If V has finite area inside Ω, is it necessarily true that V is the zero set of some bounded analytic function on Ω? Bo Berndttson (no citation) has shown that the answer is `yes' when $\Omega$ is the ball; and easy examples show that the answer is `no' for strictly pseudo-convex domains in $\mathbb{C}$ when $n > 2$. Skoda (,) and independently Henkin have shown (under some cohomology condition on Ω) for all n that V is the zero set of a function of Nevanlinna class only if V satisfies the Blaschke condition. (R. Zeinstra)

Given an associative algebra A, with identity 1 and countable basis, then for a finite-dimensional subspace V spanned by the vectors $\{e_j\}^k_{j=1}$ we have the differential operator \[\sum^k_{j=1}e_j\frac{\partial}{\partial x_j}\] acting on differentiable functions defined over domains in V and taking their values in A. We call a function $f: U\subseteq V\to A$ a left analytic function if \[\sum^k_{j=1}e_j\frac{\partial f}{\partial x_j}(x)=0\] for all $x\in U$. Ryan has shown that there is a generalised Cauchy integral formula \[f(x_0)=\int_{\partial M}G(x,x_0)\sum^k_{j=1}(-1)^je_j\,d\hat{x}_jf(x),\] with real-analytic kernel $G(x,x_0)$, where M is an arbitrary, compact real n-dimensional manifold lying in U; and $x_0\in \mathring{M}$ if and only if there are elements $\{p_j\}^k_{j=1}\subseteq A$ satisfying the relation \[p_je_l+p_le_j=2\delta_{jl}.\] [(a)] ; Is the result still valid if we only assume $G(x,x_0)$ to be a C^1 function? ; What analogous result holds if we assume the algebra to be non-associative? In their famous Acta paper , Hardy and Littlewood introduced the celebrated Hardy-Littlewood maximal function in connection with complex function theory. Since then it has proved an invaluable tool in real analysis. Here we ask some questions about the dependence of constants on dimension. Let B be a convex compact symmetric body in $\mathbb{R}^n$, normalised to have Euclidean volume 1. Let the Hardy-Littlewood maximal functions be \[Mf(x)= \sup_{t>0}\big(\frac{1}{t^n}\int_{tB}|f(x+y)|\,dy\Big)\] and \[\tilde{M}f(x)=\sup_{k\in Z}\big(\frac{1}{2^{kn}}\int_{2^kB}|f(x+y)|\,dy\Big).\] [(a)] ; If B is the Euclidean ball in $\mathbb{R}^n$, does there exist a constant C such that $\text{meas}\{x:\tilde{M}f(x)>\lambda\}\leq C\lambda^{-1}\|f\|_1$ for all $\lambda> 0$, with C independent of n? ; If so, what is the answer to the same question for Mf? ; In the case that $n = 1$, a conjecture of F. Sonia and the proposer is that the best constant in the inequality $\text{meas}\{x:Mf(x)>\lambda\}\leq C\lambda^{-1}\|f\|_1$ is $C = \frac{3}{2}$. Prove this. ; Let $1<p\leq\frac{3}{2}$. Can the best constant in the inequality \[\|Mf\|_p\leq C_p\|f\|_p\] be taken to be independent of n and the body B? Even if $B = [-\frac{1}{2},\frac{1}{2}]^n$, can the constant be chosen independent of n? The following relevant facts are known. For (a) and (b), the best known constants are found in . For (c), Sonia and the proposer have shown that the answer is `yes' if $\frac{3}{2}< p \leq\infty$; for $B$ with suitably-curved boundary, the answer is `yes' for $1< p\leq\infty$; for the sphere, see . Let $L = \{L\}^\infty_0$ be a non-negative increasing sequence such that \[\sum^\infty_{k=0}L_kr^k<\infty\hspace{1cm}(0<r<1).\] If $f(z)$ is analytic in $|z|< 1$, we will say that $f\in\mathcal{P}_L$ if there exists a constant A such that, for each integer $n\geq0$ and each polynomial P_n of degree n, \[\|P_n\ast f\|_\infty\leq AL_n\|P\|_\infty,\] where $\ast$ denotes the Hadamard product. The infimum of such A for a given $f\in\mathcal{P}_L$ defines a norm on $\mathcal{P}_L$ which then becomes a Banach space. A variety of linear operators (such as subordination) have the property that they are norm-decreasing on $\mathcal{P}_L$. This enables one to obtain sharp coefficient inequalities for subordinate functions etc., once a function has been shown to lie in $\mathcal{P}_L$. The spaces $\mathcal{P}_L$ are `large-growth' spaces; for example, the case $L_k = 1$ $(k\geq 0)$ is the space of Cauchy-Stieltjes transforms. Convex sequences $\{L_k\}^\infty_0$ (such as $L_k = k$) have the property that \[\sum^\infty_{k=0}L_kz^k\] lies in the unit ball of $\mathcal{P}_L$. Can one relate known spaces to these spaces, for example H^p, for $0 < p < 1$? (T. Sheil-Small)

For a bounded plane domain D, denote by $N(D)$ the class of functions analytic on D of bounded characteristic (i.e., all quotients of functions in $H^\infty(D)$ with nonvanishing denominator); let $f_1,\ldots,f_N\in N(D)$ have no common zeros in D. Find necessary and sufficient conditions on $f_1,\ldots,f_N$ in order that they generate the full ring $N(D)$. Equivalently, if $g_1,\ldots,g_N\in H^\infty(D)$, when does the ideal generated by $g_1,\ldots,g_N$ in $H^\infty(D)$, or in $N(D)$, contain a non-vanishing function? For $D = \mathbb{D}$, for example, the zeros of $g_1,\ldots,g_N$ should not get too close together as one approaches ∂D, and one would like to obtain a corona-type theorem for this problem - i.e., a lower estimate for \[|g_1(z)|+\ldots|g_N(z)|\] in $\mathbb{D}$. We use the notation of Problem 8.6. Let $\{z_n\}^\infty_1$ be a sequence of points in $\mathbb{D}$ such that the kernel functions $k_n(z) = (1-z_nz)^{-2}$ do not span the space A^2, and let $\{f_j\}^\infty_1$ be finite linear combinations of the k_n which converge (in norm) to some function f in A^2. Prove that, if the sequence $\{f_j\}$ converges uniformly to 0 on some disc Δ in $\{|z| > 1\}$, then $f\equiv0$. Similar problems can of course be stated for the functions $(1- z_nz)^{-1}$, and for spaces other than A^2. This slightly `weird' problem arises in the theory of generalised analytic continuation; it is known to be true if the closure of $\{z_n\}^\infty_1$ does not contain all of $\{|z| = 1\}$; it is also known that the analogous result for H^2 is true. Residual obstruction to Artin approximation of formal CR maps

P / partially_solved | AIM 研讨会问题汇编

Let \[0\in M\subset \mathbb C^n,\qquad 0\in M'\subset \mathbb C^N \] be real-analytic CR manifolds, both of Bloom--Graham--Kohn finite type, and let \[f:(\mathbb C^n,0)\longrightarrow(\mathbb C^N,0) \] be a formal holomorphic map that sends (M) into (M') formally. Is it true that, for every integer \(\ell>0\), there is a convergent holomorphic germ \[f^\ell:(\mathbb C^n,0)\longrightarrow(\mathbb C^N,0) \] such that (f^\ell(M)\subset M') and \[j_0^\ell f^\ell=j_0^\ell f? \]

If \(\rho\) and \(\rho'\) are defining functions, formal containment means, invariantly, that substitution by \((f,\bar f)\) sends the defining ideal of \(M'\) into the completed defining ideal of \(M\). In the hypersurface case this can be written \[\rho'(f(z),\bar f(\bar z))=a(z,\bar z)\rho(z,\bar z). \] For higher codimension, \(\rho,\rho'\) are vector-valued and \(a\) is a matrix of formal series.

1. the approximating map is printed with codomain \(\mathbb C^n\); it must have codomain \(\mathbb C^N\); 2. the final informal “complexity” sentence subtracts \(N\) from the dimension of an analytic set containing the graph. A graph over \(\mathbb C^n\) has dimension \(n\), so the natural excess dimension is \(\dim A_f-n\), not \(\dim A_f-N\). Moreover, the analytic set must be specified canonically; an arbitrary containing set gives no invariant.

Scale invariance and the fibers of normalized cone-volume measure

S / solved | AIM 研讨会问题汇编

Cone-volume measure. If \(K\) and \(L\) symmetric convex bodies in \(\mathbb R^n\) such that \(\bar V_K=\bar V_L\), then \(K=L\) or \(K\) and \(L\) are parallelograms with parallel sides.

Moreover, Problem 1.15 on that same page explicitly calls \(\bar V_L\) “the cone-volume probability measure of \(L\).” Thus the bar denotes normalization, and the page does not state equal volume, dimension two, or equality up to dilation.

The statement as written cannot be correct. It has at least two independent defects:

1. normalized cone-volume measure is invariant under dilation, so it cannot distinguish \(K\) from \(cK\); 2. in dimensions \(n\geq 3\), distinct equal-volume parallelotopes with the same facet-normal directions have the same cone-volume measure, but are not parallelograms.

No silent correction is made below. Instead, the literal assertion is refuted, the known planar repair is identified, and its higher-dimensional polyhedral obstruction is classified exactly.

Schatten-Class Commutators for Homogeneous Polynomial Modules

P / partially_solved | Oberwolfach 报告问题汇编

Let M be the submodule of the Drury-Arveson space H_d^2 generated by homogeneous polynomials $p_1,\ldots,p_m\in\mathbb C[z_1,\ldots,z_d]$, let S_j be the compression of multiplication by z_j to $M^\perp$, and let $Z(p)$ be the common zero set of the generators. Are all commutators $[S_j,S_k^*]$ in the Schatten class $\mathcal S^q$ for every $q>\dim Z(p)$?

The Fatou Set of a Polynomial Automorphism of $\mathbb{C}^2$. Let f be a polynomial automorphism of $\mathbb{C}^2$, and suppose that f is not conjugate to an elementary map. Let Ω be a connected component of the set of points where the forward iterates $\lbrace f^n:n=1,2,3,...\rbrace $ are locally bounded, which is the Fatou set of f. Let us suppose that Ω is periodic, i.e. $f^n\Omega=\Omega$ for some $n\ne0$. Let us first consider the case in which Ω is recurrent, i.e. Ω contains a point whose orbit does not converge to $\partial\Omega$. In this case Ω is either (a) a basin of attraction of a sink orbit, (b) the basin of attractin of a Siegel disk, or (c) the basin of a Herman ring. It is not hard to construct examples of (a) and (b).\\ (i) Can case (c) occur? Nothing at all seems to be known about periodic domains which are not recurrent.\\ (ii) If Ω is not recurrent, does there exist $P\in\partial\Omega$ such that $\lim_{k\to\infty}f^{nk}(Q)=P$ for all $Q\in\Omega$?\\ (iii) If Ω is not recurrent, does there exist $P\in\partial\Omega$ such that $f^nP=P$, and one of the eigenvalues of $DF(P)$ is $e^{2\pi ip/q}$?\\ -E. Let $\Omega \subseteq \mathbb{C}^n$ be a bounded domain with complete Kobayashi metric. Is there a constant $C = C(p) > 0$ such that if f is holomorphic and $p > 0$ then for all $z \in \Omega$ and all $r > 0$ small it holds that $$ |f(z)|^p \leq C \frac{1}{|B(z,r)|} \int_{B(z,r)} |f(\zeta)|^p dV(\zeta) . $$ Here f is any holomorphic function and $B(z,R)$ is the Kobayashi metric ball. The measure being used is up for grabs. It can be Euclidean or one of the canonical measures associated with the Kobayashi metric construction (such as that due to Eisenman or Bun Wong). In case Ω is finite type in $\mathbb{C}^2$ or strongly pseudoconvex in any dimension then the results is true just because metric balls are comparable to polydiscs and then classical arguments of Stein (or see my SCV book) will suffice. In general I think that something like this should be true but I have no idea how to prove it.\\ -S. Krantz, sk@math.wustl.edu

Let \(M\) be a connected generic real-analytic manifold in \(\mathbb C^n\), holomorphically nondegenerate and of finite type. For \(p\in M\), let \(k(p)\) be the least \(k\) for which \[\operatorname{Aut}_M(p)\longrightarrow G^k(\mathbb C^n), \qquad f\longmapsto j_p^k f \tag{1.1} \] is injective. Does there exist such an \(M\subset\mathbb C^2\) and a sequence \(p_j\in M\) with \(k(p_j)\to\infty\)?

Comment: such an \(M\) exists in higher dimensions.

If \(M\) is only generically of finite type, does there exist an \(M\) as above with \(p_j\) converging to a point of \(M\)?

It contains the running header “AIM WORKSHOP ON COMPLEXITY OF MAPPINGS IN CR GEOMETRY 3” inside the phrase “of finite type” and flattens subscripts and superscripts in the jet map.

Here \(\operatorname{Aut}_M(p)\) is the stability group of germs at \(p\) of local biholomorphisms of the ambient space fixing \(p\) and preserving the germ \((M,p)\); \(G^k(\mathbb C^n)\) is the group of invertible \(k\)-jets after centering \(p\) at the origin. For real-analytic finite-type hypersurfaces, this agrees with the corresponding group of germs of real-analytic CR automorphisms.

The PDF really says “generic real analytic manifold,” not “hypersurface.” In \(\mathbb C^2\), however, a positive-dimensional generic submanifold of positive CR dimension and finite Bloom--Graham type must have real codimension one, hence is a hypersurface. A codimension-two generic submanifold has CR dimension zero and cannot generate its tangent bundle by CR brackets.

Sharp decay for bounded-degree chirps along null directions

P / partially_solved | AIM 研讨会问题汇编

\[e^{i\lambda x_3^2}, \]

the exponent on the right is a positive \(\epsilon\), and the isolated `1` before “So far” is the page number. Thus the displayed question is

\[\left|\int_B e^{i\lambda x_3^2} \prod_{j=1}^N f_j(x\cdot v_j)\,dx\right| \lesssim \lambda^{-\epsilon}\prod_{j=1}^N\|f_j\|_\infty, \tag{1.1} \]

where \(B\) is the unit ball in \(\mathbb R^3\).

This cannot be the intended CLTT datum, since CLTT use \(V_j\) for linear subspaces. The mathematically coherent reconstruction is corroborated by the exact model in Oliveira e Silva's exposition of the CLTT problem:

\[\Gamma=\{v\in\mathbb R^3\setminus\{0\}:v_3^2=v_1^2+v_2^2\}, \qquad v_j\in\Gamma,\qquad V_j=\operatorname{span}(v_j), \tag{1.2} \]

with the lines \(V_j\) distinct and \(\pi_j(x)=x\cdot v_j\). Unit normalization of the \(v_j\) is harmless because it can be absorbed into \(f_j\). This reconstruction also exactly explains the source's statement that (1.1) was known for \(N\leq5\). All results below use (1.2), and no silent claim is made for the literal, undefined “different light cones” wording.

11511 | AIM-FUNCTIONAL_ANALYSIS-0004

Source repair and exact Cartesian factorization for L_p-Wulff combinations

P / partially_solved | AIM 研讨会问题汇编

It reads, verbatim in the relevant place, \[\bigcap_{u\in S^{n-1}}\left\{x\in\mathbb R^n:\ \left\leq \left(t h_K(u)^p+(1-t)h_L(u)^p\right)^{1/p}\right\}.

The intended expression is nevertheless unambiguous from the primary source of this formulation, Böröczky--Lutwak--Yang--Zhang (2012), equation (1.8): it is \[\langle x,u\rangle\leq \left(t h_K(u)^p+(1-t)h_L(u)^p\right)^{1/p}. \tag{1.1} \] Thus, for \(p>0\), define the Wulff body \[W_p(t;K,L):=\bigcap_{u\in S^{n-1}} \left\{x\in\mathbb R^n: \langle x,u\rangle\leq M_{p,t}(h_K(u),h_L(u))\right\}, \tag{1.2} \] where \[M_{p,t}(a,b)=\left(t a^p+(1-t)b^p\right)^{1/p}. \] For \(p=0\), the displayed \(1/p\) expression is undefined. For \(0<t<1\), its limiting reconstruction on the positive quadrant is \[M_{0,t}(a,b)=a^t b^{1-t}, \qquad W_0(t;K,L)=\bigcap_{u\in S^{n-1}} \{x:\langle x,u\rangle\leq h_K(u)^t h_L(u)^{1-t}\}. \tag{1.3} \] Indeed, for \(a,b>0\), taking logarithms and expanding \(a^p,b^p\) at \(p=0\) gives \(M_{p,t}(a,b)\to a^t b^{1-t}\). We extend this mean continuously to \([0,\infty)^2\): for \(0<t<1\), \(M_{0,t}(a,b)=0\) if \(ab=0\), including \(M_{0,t}(0,0)=0\). For every \(p\geq0\), the endpoint weights are defined separately by \[M_{p,0}(a,b)=b,\qquad M_{p,1}(a,b)=a. \] This convention avoids every \(0^0\) ambiguity. For \(p>0\), the displayed power-mean formula already extends continuously to the closed nonnegative quadrant.

The recovered AIM conjecture is \[|W_p(t;K,L)|\geq |K|^t|L|^{1-t}, \qquad 0\leq t\leq1,\quad p\geq0, \tag{1.4} \] for **origin-symmetric** convex bodies \(K=-K\), \(L=-L\). “Symmetric” cannot mean symmetry about arbitrary centers because the construction is tied to the origin.

For \(0<p<1\), the function in the right side of (1.1) need not itself be a support function; the intersection/Wulff operation is essential. For \(p\geq1\), it is a support function.

The AIM display (1.4) is pointwise weaker than the standard homogeneous \(L_p\)-Brunn--Minkowski inequality \[|W_p(t;K,L)|^{p/n} \geq t|K|^{p/n}+(1-t)|L|^{p/n}, \qquad p>0, \tag{1.5} \] because weighted arithmetic--geometric mean applied to \(|K|^{p/n}\) and \(|L|^{p/n}\) turns (1.5) into (1.4). They should not be silently identified for one fixed triple \((K,L,t)\): their equality cases can differ. However, Proposition 5.1 below shows that their **universal** versions (all bodies and all weights, at a fixed \(p>0\)) are equivalent by homogeneity and volume normalization. At \(p=0\), (1.5) tends exactly to (1.4).

11515 | AIM-ANALYSIS-0140

Spectral arbitrariness of the tridiagonal T_n sign pattern

S / solved | AIM 研讨会问题汇编

Normalized statement. For every \(n\geq2\) and every monic \(q\in\mathbb R[x]\) of degree \(n\), there is \(A\in Q(\mathcal S_n)\) such that \(\chi_A=q\).

Tyaglov and supplies no further status or hypotheses. In sign-pattern terminology, every \(+\) means a strictly positive real entry, every \(-\) a strictly negative real entry, and every \(0\) an exact zero. Denote this order-\(n\) sign pattern by \(\mathcal S_n\), and its qualitative class by \(Q(\mathcal S_n)\).

Two corrections are required to make the sentence literally true.

1. For every real \(n\times n\) matrix, \[\det(A-\lambda I)=(-1)^n\lambda^n+\text{lower-degree terms}. \] Thus exact equality is possible only for degree-\(n\) polynomials with leading coefficient \((-1)^n\). Equivalently, the characteristic polynomial \(\chi_A(x)=\det(xI-A)\) can be any **monic** real polynomial of degree \(n\). An arbitrary nonzero real polynomial is a scalar multiple of such a determinant, not necessarily the determinant itself. 2. The fixed pattern starts at \(n=2\). At \(n=1\), its sole diagonal entry would have to be both positive and negative.

The recovered assertion is therefore:

This is the statement that \(\mathcal S_n\) is **spectrally arbitrary**.

11524 | AIM-SEVERAL_COMPLEX_VARIABLES-0053

Spherical CR boundaries and Veronese quotient singularities

P / partially_solved | AIM 研讨会问题汇编

Let \(M\subset\mathbb C^N\) be a compact real-analytic spherical CR manifold of hypersurface type, and suppose that \(M\) is the boundary of an analytic variety \(V\). What kinds of singularities can \(V\) have?

Problem 13 in the AIM workshop list *Complexity of mappings in CR geometry*, proposed by Xiaojun Huang, asks:

The source adds that in the algebraic case the filling has at most one isolated singular point, citing [HJ] and Huang's survey [H]. Direct inspection of the PDF verifies the intended reconstruction: \[f:\mathbb B^2\longrightarrow\mathbb B^3,\qquad f(z_1,z_2)=(z_1^2,\sqrt2\,z_1z_2,z_2^2), \] and the polynomial extension \(F:\mathbb C^2\to\mathbb C^3\) has image \[X=\{w\in\mathbb C^3:Q(w)=w_2^2-2w_1w_3=0\}. \] The restricted image and its relative boundary are \[V=f(\mathbb B^2)=X\cap\mathbb B^3,\qquad M=f(S^3)=X\cap S^5. \] Indeed, \[\|f(z)\|^2 =|z_1|^4+2|z_1z_2|^2+|z_2|^4 =\bigl(|z_1|^2+|z_2|^2\bigr)^2. \]

1. The image of \(f:\mathbb B^2\to\mathbb B^3\) is not the entire unbounded cone \(X\); the polynomial extension \(F:\mathbb C^2\to\mathbb C^3\) has image \(X\), while \(f(\mathbb B^2)=X\cap\mathbb B^3\). 2. The PDF says that \(M\) has one singularity, then computes \[\nabla Q=(-2w_3,2w_2,-2w_1). \] This proves that the affine cone \(X\), and hence the filling \(V\), has its unique singularity at \(0\). It does **not** prove that \(M\) is singular. In fact \(0\notin M\), because \(|f(z)|=1\) on \(S^3\), and \(M\) is smooth.

Here “hypersurface type” means CR codimension one: if \(V\) has complex dimension \(d\), then \(M\) has real dimension \(2d-1\) and CR dimension \(d-1\). It need not be a real hypersurface of the larger ambient \(\mathbb C^N\). “Boundary” is the boundary relative to the analytic filling (or its closure), not the ambient topological boundary in \(\mathbb C^N\).

11567 | AIM-ANALYSIS-0102

The scalar-and-zero mixed-characteristic extremizer in dimension two

P / partially_solved | AIM 研讨会问题汇编

"There's a conjecture about repeated copies of Identity with zero padding that this gives you the worse bounds on roots?"

The original workshop document places the sentence under a heading for Adam Marcus. The next bullets discuss using interlacing polynomials when only the maximum root is wanted and using rank-two rather than rank-one perturbations. Thus “worse” is almost certainly “worst,” and “roots” should not be read as coordinatewise extremality of every root.

There is an essentially exact match in Marcus--Spielman--Srivastava (MSS), Section 7.2, page 346. For positive semidefinite Hermitian matrices \(A_1,\ldots,A_m\in\mathbb C^{d\times d}\), define

\[\mu[A_1,\ldots,A_m](x) =\left.\prod_{i=1}^m(1-\partial_{z_i}) \det\!\left(xI_d+\sum_{i=1}^m z_iA_i\right) \right|_{z_1=\cdots=z_m=0}. \]

The precise recovered conjecture is:

MSS scalar-and-zero extremizer conjecture. Fix \(d,m\) and \(\epsilon>0\), and suppose the feasible set

\[\mathcal F_{d,m,\epsilon} =\left\{(A_i)_{i=1}^m:A_i\succeq0, \ \sum_iA_i=I_d,\ \operatorname{tr}A_i\leq\epsilon\right\} \]

is nonempty. The largest root of \(\mu[A_1,\ldots,A_m]\) is maximized by taking as many matrices as possible equal to \(\epsilon I_d/d\), one further smaller scalar multiple of \(I_d\) if needed, and all remaining matrices zero. Explicitly, with

\[q=\left\lfloor\frac d\epsilon\right\rfloor, \qquad s=d-q\epsilon\in[0,\epsilon), \]

the proposed family consists of \(q\) copies of \((\epsilon/d)I_d\), one copy of \((s/d)I_d\) when \(s>0\), and zero matrices filling the remaining slots. Feasibility implies \(m\geq\lceil d/\epsilon\rceil\), so this family fits.

Two kinds of “padding” occur in the source material and probably became compressed in the workshop shorthand. The conjectured family is padded by zero matrices. In the paragraph immediately before the conjecture, MSS also define a partial mixed discriminant by padding its arguments with identities:

\[D(A_1,\ldots,A_k) =\frac{D(A_1,\ldots,A_k,I_d,\ldots,I_d)}{(d-k)!}. \]

The recovered conjecture concerns **only the largest root**. Section 8 below gives a counterexample to the stronger all-roots reading.

Does every nuclear C*-algebra belong to the bootstrap class?

Small Bootstrap Problem. Is every separable nuclear C*-algebra in Blackadar's Small Bootstrap Class $\mathsf B$?

来源字段：http://aimpl.org/settheorycstar/4/

11569 | AIM-ANALYSIS-0067

The solved discrete quadratic Carleson problem and a sharp-scale finite sampling reduction

S / solved | AIM 研讨会问题汇编

3 of the authoritative AIM PDF. The PDF asks for the discrete analogue of Stein--Wainger's polynomial Carleson theorem:

\[\left\| \sup_{\lambda} \left| \sum_{m\in\mathbb Z} f(n-m)\frac{e^{i\lambda m^2}}{m} \right| \right\|_{\ell^2_n} \lesssim \|f\|_{\ell^2}. \tag{0.9} \]

It then takes \(\Lambda\subset[0,1]\), replaces the unrestricted supremum by \(\sup_{\lambda\in\Lambda}\), and cites Krause--Lacey for a sufficient condition for boundedness of that restricted operator.

Two repairs/conventions are forced by the display and by the cited paper.

1. The term \(m=0\) is undefined and must be omitted. The infinite sum is the symmetric principal value \[\lim_{N\to\infty}\sum_{0<|m|\leq N} f(n-m)\frac{e^{i\lambda m^2}}{m}. \] Krause--Lacey explicitly write \(m\ne0\). 2. The source uses \(e^{i\lambda m^2}\), while the later literature normally writes \(e(\alpha m^2)\), where \(e(t)=e^{2\pi i t}\). The change \(\alpha=\lambda/(2\pi)\) is harmless for the unrestricted supremum. We use the latter convention, for which the parameter belongs naturally to \(\mathbb T=\mathbb R/\mathbb Z\).

Thus the clean recovered operator is

\[\mathcal C_2 f(n) :=\sup_{\lambda\in\mathbb T} \left|\operatorname{p.v.}\sum_{m\ne0} f(n-m)\frac{e(\lambda m^2)}{m}\right|. \tag{1.1} \]

The norm in (0.9) is the sequence norm in the free variable \(n\in\mathbb Z\).

O / open | AMR 问题清单汇编

For the next few problems, recall the equivalence relation of sequantial commutation [elayavalli2023sequential] on the haar unitaries in a II$_1$ factor. For $u,v\in \mathcal{H}(N)$ haar unitaries, say that $u\sim_{N^\mathcal{U}} v$ if there exists a finite set $w_1, \cdots, w_n$ of haar unitaries in $N^{\mathcal{U}}$, such that $[u, w_1]=[w_1,w_2]= \cdots = [w_{n-1}, w_n]= [w_n,v]=0$. In the case that there is a unique orbit among haar unitaries, additionally recall the commutation diameter $\mathfrak{O}(M) := \sup_{u,v\in \mathcal{H}(N)} p_N(u,v)$, where $p_N(u,v)$ denotes the length of the shortest path of sequentially commuting haar unitaries in the ultrapower connecting u and v.

Does there exist a non Gamma factor with unique sequential commutation orbit, and has sequential diameter equal to n, $n\in \mathbb{N}$?

Recall that an embedding of $\iota: N\hookrightarrow M$ is existential if there is an embedding of $M\subset N^{\mathcal{U}}$ that restricts to the diagonal embedding under ι. One can define this notion similarly for inclusions of groups.

Does there exist a separable N admitting an existential embedding $L(\mathbb{F}_2)\subset N$ and moreover satisfies N is not isomorphic to a non trivial free product?

Which web is meant by a Gaussian free-field zero set?

P / partially_solved | AIM 研讨会问题汇编

Question 10: Scott Sheffield Consider a function who Fourier transform is white noise on the unit circle. We aim to understand the web like appearance, that is the zero level lines of the Gaussian free field. Zelditch and Schramm make the above question more precise.

Direct inspection of the two-page source PDF gives the exact text:

There is no additional definition or nearby clarification after Question 10.

The two sentences do not specify one mathematical object. Three readings must be separated.

1. **White noise supported on the frequency circle.** In the conventional random-wave reading, the inverse Fourier transform of Gaussian white noise on $S^1\subset\mathbb R^2$ is the monochromatic Gaussian plane wave. It is a real-analytic random function satisfying the Helmholtz equation, so its pointwise zero set is a genuine collection of curves. 2. **White noise as a boundary distribution.** White noise on the spatial circle has independent Fourier coefficients and is not a pointwise function. Its Poisson extension is a smooth harmonic function in the open disk, completely determined by the boundary distribution. Neither the boundary noise nor this harmonic extension is the two-dimensional zero-boundary GFF. 3. **The two-dimensional GFF.** The continuum GFF has Fourier multiplier $|\xi|^{-1}$ applied to bulk white noise, or covariance multiplier $|\xi|^{-2}$. It uses all radial frequencies and is a random distribution, not a function. Consequently, a raw set $\{z:h(z)=0\}$ is undefined. Canonical “level lines” require boundary data and a local-set/Markov characterization, or a specifically proved approximation scheme.

Zelditch later explicitly distinguished the almost-fixed-frequency random wave ensemble, whose proposed percolation-type scaling is associated conjecturally with SLE_6, from cutoff GFF ensembles associated with SLE_4 [3]. This supports treating the AIM text as a compact juxtaposition of two web questions, not as an identity between the plane wave and the GFF.

The reconstructed research tasks are therefore:

- determine what is rigorously known about the monochromatic plane-wave nodal web; - state the now-canonical meaning of GFF level lines and loop webs; - determine what, if anything, can be inferred for raw smooth or Fourier truncation zero sets.

A coherent-stretching diagnostic for exponential material-line growth

P / partially_solved | AIM 研讨会问题汇编

Exponential growth of the length of Lagrangian flow map for 2D Euler.

Find a solution \(u\) of 2D Euler with \[\sup_t \|u\|_{C^1(\mathbb T^2)}<\infty, \] and a curve, \(l\), of finite length such that the length of \(\Phi_t(l)\) grows exponentially in time. Here, \(\Phi_t\) is the Lagrangian flow map of \(u\).

Recovered working statement. Find a global classical solution of two-dimensional incompressible Euler on \(\mathbb T^2\), a regular embedded \(C^1\) curve \(\gamma:[0,L_0]\to\mathbb T^2\), and constants \(c,\lambda>0\) such that \[\sup_{t\geq0}\|u(t)\|_{C^1}<\infty, \qquad \mathcal L(t):=\operatorname{Length}(\Phi_t\circ\gamma) \geq c e^{\lambda t}\quad(t\geq0). \] Length means material arclength, with the initial parametrization carried by the flow. It does **not** mean an operator norm of \(\Phi_t\). Because \(\Phi_t\) is a diffeomorphism, an initially embedded curve stays embedded.

A positive four-velocity kinetic profile and its transverse Evans determinant

P / partially_solved | AIM 研讨会问题汇编

P. Szmolyan: (Kinetic and Boltzmann Equations)

but then includes Y. Li's water-wave heading and setup. The original AIM PDF was inspected directly. On page 2, immediately before this question, it has

\[f_t+v\mathbin{\cdot}f_x=Q(f,f),\qquad f=f(x,v,t),\quad x\in\mathbb R^d, \tag{1.1} \] followed by

\[(v-c)f'=Q(f,f). \tag{1.2} \] The PDF text stream itself drops the equality sign between \(v\cdot f_x\) and \(Q(f,f)\); (1.1) is the unambiguous reconstruction from the displayed kinetic equation and its profile equation. The line break “pertur-bations” is only line-end hyphenation. After the parenthetical suggestion about discrete velocities, the PDF starts a new heading, “Y.

There is one additional notational compression. For a planar wave normal to \(x_1\), with \(z=x_1-ct\), the multidimensional kinetic equation gives

\[(v_1-c)\bar f'(z)=Q(\bar f(z),\bar f(z)), \qquad \bar f(\pm\infty)=f_\pm. \tag{1.3} \] Thus the scalar \(v-c\) in (1.2) is read as the normal velocity \(v_1-c\). The recovered problem is:

1. under what collision, end-state, and speed conditions does (1.3) have a positive heteroclinic profile; 2. when is that planar profile stable to perturbations depending on transverse spatial variables; and 3. how should an Evans function be constructed for the resulting kinetic spectral problem?

An exact annular inflow-outflow boundary layer

P / partially_solved | AIM 研讨会问题汇编

Vanishing viscosity limit in a setting like Temam--Wang.

Study the vanishing viscosity limit from Navier-Stokes to Euler on the annulus in a setting like the work of Temam and Wang, with in-flow and out-flow conditions.

Recovered working statement. Let \[A_{r_-,r_+}=\{x\in\mathbb R^2:r_-<|x|<r_+\}, \qquad 0<r_-<r_+. \] For smooth, compatible inflow/outflow data whose normal component is nonzero on both boundary components, prove that solutions \(u^\nu\) of incompressible Navier--Stokes converge as \(\nu\downarrow0\) to a smooth solution \(u^0\) of incompressible Euler, identify the outflow boundary layer, and quantify convergence.

来源字段：http://aimpl.org/smallscalefluid/9/

11716 | AIM-PDES-0056

An explicit two-family viscous corner layer

P / partially_solved | AIM 研讨会问题汇编

Williams, “Two Interacting Shocks in 1D,” in the AIM workshop list *Open Problems in Multidimensional Stability of Waves and Patterns* (2005). The setup is

\[u_t+f(u)_x=0 \tag{A} \]

and its identity-viscosity regularization

\[u_t^\varepsilon+f(u^\varepsilon)_x =\varepsilon u^\varepsilon_{xx}, \qquad u\in\mathbb R^2,\quad x\in\mathbb R. \tag{B} \]

The recovered problem asks whether one can construct explicit solutions of (B), “say of the form \(u^\varepsilon(t,x,t/\varepsilon,x/\varepsilon)\),” converging reasonably to solutions of (A), while explicitly resolving the dynamics at the corner where \(U_l\) and \(U_r\) meet in the \(xt\)-plane.

The original PDF was checked directly. Thus the displayed target is a forward two-shock Riemann fan, normally involving two distinct characteristic families, not the merger of two scalar same-family shocks. The source sentence says “two-shock solution to the viscous conservation law,” although the sharp sector diagram is naturally the inviscid pattern; this apparent wording slip is recorded rather than silently altered.

Humphreys, K. Promislow, and B. Sandstede entries. Those entries are not part of AIM-PDES-0056 and are excluded here.

11723 | AIM-PDES-0093

Arnold diffusion, radial genericity, and separatrix-map actions

P / partially_solved | AIM 研讨会问题汇编

Problem 23 (Arnold diffusion). Consider a \(C^r\), \(3\le r\le\omega\), Hamiltonian \[H_\varepsilon:\mathbb T^n\times\mathbb R^n\times\mathbb T\to \mathbb R,\qquad H_\varepsilon(x,p,t)=H_0(p)+\varepsilon H_1(x,p,t), \] where \(H_0\) is positive definite and superlinear. Suppose \(n\ge2\). Given open sets \(U_0,U_1\subset\mathbb R^n\), is it true that for a typical \(H_1\) in the \(C^r\) topology there is \(\varepsilon_0>0\) such that, for **every** \(\varepsilon\in(0,\varepsilon_0)\), some trajectory satisfies \(p(t_0)\in U_0\) and \(p(t_1)\in U_1\)? What is the right meaning of “typical”? Does Mather's \(n=2\) cusp-residual theorem hold within trigonometric polynomials of sufficiently high order \(N\)?

Problem 24. Consider an *a priori* unstable Hamiltonian \[H(\theta,I,x,y)=H_0(I)+F(x,y)+\varepsilon H_1(\theta,I,x,y) \] on \(\mathbb T^n\times\mathbb R^n\times\mathbb R^2\), where \(H_0\) is convex and superlinear, \(F\) has a separatrix loop, and \(H_1\) is generic. Understand the relation between Mather--Xia variational methods and the separatrix-map method; they seem similar in spirit.

11744 | AIM-PDES-0046

Boundary-audited toric Calabi dissipation and a global product family

P / partially_solved | AIM 研讨会问题汇编

What is the behavior of $g_{j\overline k}(t)$ solving the Calabi flow, \[\frac{\partial}{\partial t}g_{j\overline k} =\partial_j\partial_{\overline k}R? \] Can long time existence be established for toric surfaces?

Recovered statement. Let (X^n,J,ω_0) be a compact Kähler manifold of complex dimension n, let $[\omega_0]$ be fixed, and let \[\omega_{\varphi(t)}=\omega_0+\sqrt{-1}\,\partial\bar\partial\varphi(t)>0 \] start from a smooth Kähler metric. With $S(\omega_\varphi)$ denoting scalar curvature and $\bar S$ its class-dependent average, use the convention \[\partial_t\varphi=S-\bar S, \qquad \partial_tg_{j\bar k}=\partial_j\partial_{\bar k}S. \tag{1.1} \] If X is a compact toric surface and the initial metric is invariant under its compact torus, does the unique smooth solution exist for all $t\geq0$? What can be said about convergence, possibly after the extremal automorphism and hence for the modified Calabi flow?

Branch-point resonances and parabolic time decay

P / partially_solved | AIM 研讨会问题汇编

For which more general parabolic systems can a zero of an Evans function at a branch point of the spatial dispersion relation be related rigorously to the leading large-time decay of the linear Green function and, through nonlinear estimates, to the decay of perturbations of a coherent structure?

In the original AIM PDF, the entry is headed by B. Sandstede and begins with the observation that an Evans function can often be extended to branch points of the linear dispersion relation. It then says that Murata showed that the temporal decay rates for scalar linear heat equations depend strongly on the presence of roots at those branch points. The open problem is, verbatim,

The singular “equation” appears in the source and is probably a grammatical error; it has not been silently changed. Here “this” means the dependence of large-time Green-function decay on a threshold/branch-point root or resonance. The text beginning “S. Malham: (Biscale chaos)” belongs to the following AIM record, AIM-PDES-0058, and is not part of the present problem.

Thus the recovered mathematical question is:

Chern and slope obstructions for pseudoholomorphic plane foliations on the four-torus

P / partially_solved | AIM 研讨会问题汇编

Problem 30 (Victor Bangert). Let M^{2n} be a manifold with an almost complex structure J. A pseudo-holomorphic line is a map $f:\mathbb R^2\to M$ satisfying $$ f_y=J(f)f_x. $$ Moser proved that, for an almost complex structure J on $\mathbb T^{2n}$ which is close to a standard complex structure J_0, and any sufficiently irrational vector $v\in\mathbb R^{2n}$, there exists a foliation of $\mathbb T^{2n}$ by pseudo-holomorphic curves which is conjugate to a linear foliation by real two-planes containing v. Develop a global (non-perturbative) theory of such foliations or laminations. The theory is expected to be particularly rich for $\mathbb T^4$, due to positivity of the intersection number of pseudoholomorphic curves, analogously to the intersection number for geodesics on $\mathbb T^2$ underlying Hedlund's work.

Complex Monge-Ampere symmetry: a literal counterexample and a proper repair

S / solved | AIM 研讨会问题汇编

Let u plurisubharmonic satisfy \[\mathrm{det}(u_{j\overline k})=f(u) \] on $B_1(0)$ with Dirichlet boundary conditions, then u is rotationally symmetric.

It gives the same text verbatim and attributes Problem 1.05 to Xu-Jia Wang. Its database object has empty `intro` and `status` fields and no remarks. A Wayback CDX query found a 2019 snapshot of the same section.

The source does **not** specify:

- whether $B_1(0)$ lies in $\mathbb C^n$ or what n is (the complex indices strongly indicate $B_1\subset\mathbb C^n$); - the actual Dirichlet boundary value, in particular whether it is constant (usually normalized to zero) or arbitrary; - the regularity of u or whether it is strictly plurisubharmonic; - the sign, regularity, or monotonicity of f; - whether the determinant is classical or Bedford--Taylor/pluripotential; - whether “rotationally symmetric” means $U(n)$-invariant or invariant under all of $O(2n)$.

These are essential mathematical data. In particular, “with Dirichlet boundary conditions” ordinarily means that some boundary trace is prescribed, not that the trace is automatically constant. Under that literal reading the statement is false (Proposition 5.1 below). A natural repaired reading is the classical problem on $B_1\subset\mathbb C^n$ with constant boundary value, positive nondecreasing f, and a C^2 strictly plurisubharmonic solution. That version follows from uniqueness and unitary covariance (Theorem 5.2).

No source text is silently changed in this report. The literal claim and the repaired theorem are kept separate.

Evans diagnostics for primary and secondary cubic-autocatalysis front instability

P / partially_solved | AIM 研讨会问题汇编

S. Malham (Biscale chaos). Consider the cubic-autocatalysis system \[u_t=\delta\Delta u-uv^2, \qquad v_t=\Delta v+uv^2. \] Here \(u\) is the fuel/reactant, \(v\) is the autocatalyst, and \(\delta\) is the ratio of their molecular diffusivities. When \(\delta\sim8\), small perturbations of a planar front evolve into a complex wrinkled front. Malevanets, Careta, and Kapral, *Biscale chaos in propagating fronts*, Phys. Rev. E 52 (1995), 4724--4735, suggested that its spatiotemporal chaos has two length scales.

Open problem. What are the stability properties of the planar front? Can we understand the secondary instability by getting an Evans function for the front that arises from the [primary] instability?

11807 | AIM-PDES-0062

Evans functions at an algebraic threshold

P / partially_solved | AIM 研讨会问题汇编

Open Problem: Can one construct an Evans function for this problem? If so, how does it behave? Note that for this problem the absolute spectrum touches the essential spectrum so there is no exponential dichotomy that we can exploit.

M. Wechselberger: (Loss of hyperbolicity, algebraic decay and the Evans function). For certain values of \(p\), the generalized KdV equation \(u_t-u_{xxx}+u_x^p=0\) admits standing waves \(\phi(x)\) which decay exponentially to zero as \(|x|\to\infty\). However, the eigenfunctions of the operator obtained by linearizing about \(\phi\) need not decay exponentially and depending on the power \(p\) (say \(p=5\)) may only decay algebraically.

11808 | AIM-PDES-0078

Exact flat-torus Mather quotient and current status

P / partially_solved | AIM 研讨会问题汇编

Inspection of page 3 of the original AIM PDF (PDF page 2), version 15 August 2003, supports the following recovery.

- The symbol after \(TM\times\) is \(\mathbb T=\mathbb R/\mathbb Z\), the time circle. Thus \(L:TM\times\mathbb T\to\mathbb R\) is a one-periodic time-dependent Tonelli Lagrangian. - The class is \(c\in H^1(M;\mathbb R)\), not homology \(H_1\). The PDF's superscript was flattened in extraction, and the following instruction to choose a closed one-form confirms the cohomological reading. - Since the PDF writes \(\mathcal A_c\subset M\), while a time-periodic projected Aubry set naturally lives in \(M\times\mathbb T\), \(\mathcal A_c\) is the projected time-zero section. This is also forced by paths running from time \(0\) to the integer time \(n\). - The broken strings hnc, ∫ n > 0, and lim inf > n→∞ recover as \(h_c^n\), \(\int_0^n\), and \(\liminf_{n\to\infty}\). The word probablility is misspelled in the PDF itself and is editorially recovered as “probability.”

Precisely, choose a closed one-form \(\eta_c\) with \([\eta_c]=c\), and set

\[L_c(x,v,t)=L(x,v,t)-\eta_c(x)[v]+\alpha(c), \qquad \min_{\mu\ {\rm invariant}}\int_{TM\times\mathbb T}L_c\,d\mu=0. \tag{1.1} \]

For \(x,y\in M\) and \(n\in\mathbb N\),

\[h_c^n(x,y)=\inf_{\substack{\gamma(0)=x\\\gamma(n)=y}} \int_0^n L_c(\gamma(t),\dot\gamma(t),t)\,dt, \tag{1.2} \]

where the infimum is over absolutely continuous curves. On the time-zero projected Aubry set \(\mathcal A_c\), define

\[\rho_c(x,y)=\liminf_{n\to\infty}h_c^n(x,y) +\liminf_{n\to\infty}h_c^n(y,x). \tag{1.3} \]

The metric quotient by \(\rho_c=0\) is \(\overline{\mathcal A}_c\). Mather asks whether it is always totally disconnected and whether its Hausdorff dimension in the induced Mather metric is zero.

11809 | AIM-PDES-0011

Exact pushed-front benchmark and pulled spectral obstruction

P / partially_solved | AIM 研讨会问题汇编

A starting point for the above problem would be

Prove existence and stability for pushed or pulled fronts for a toy model using a computer assisted proof.

It also supplies the context omitted by the words "the above problem": Problem 2.1, attributed to Arnd Scheel, asks for existence and stability of pulled fronts for the complex Ginzburg--Landau equation. Problem 2.2 proposes a toy model as a starting point.

The intended phrase is almost surely "existence and marginal stability," but this reconstruction is not silently substituted for the source.

The 2023 AIM workshop announcement emphasizes two complementary rigorous-numerics tasks: validation of heteroclinic or homoclinic connections and computation of quantities controlling spectral stability of one-dimensional waves. This report accordingly chooses a scalar reaction--diffusion toy model and treats both profile existence and weighted spectral stability. It does **not** claim to solve the preceding complex Ginzburg--Landau problem.

11811 | AIM-PDES-0089

Exact-energy reachability at the universal Mañé critical value

P / partially_solved | AIM 研讨会问题汇编

The source file prints:

\[c_u=\inf\{h\in\mathbb R\mid \exists x\in\widetilde M\ \forall y\in M\ \exists\text{ trajectory with energy }h\text{ joining }x\text{ to }y\}. \tag{1} \]

Here \(M\) is compact, \(L:TM\to\mathbb R\) is a convex superlinear (Tonelli) Lagrangian, \(\widetilde L:T\widetilde M\to\mathbb R\) is its lift to the universal cover, and \(c_u\) is the Mañé critical value of the lift.

More importantly, the mixed quantifiers \(x\in\widetilde M\) and \(y\in M\) occur in both the official PDF and HTML.

Contreras later restated the question in the following unambiguous all-pairs form:

\[c_u(L)=\inf\{k\in\mathbb R\mid \forall x,y\in\widetilde M\ \exists\text{ an Euler--Lagrange orbit from }x\text{ to }y \text{ with energy }k\}\,? \tag{2} \]

This later version changes both parts of the problematic quantifier: \(y\) lies in \(\widetilde M\), and the base point is universally rather than existentially quantified. In the same paper, a connecting orbit is a positive-time curve \(\gamma:[0,T]\to\widetilde M\), \(T>0\), satisfying the Euler--Lagrange equation and the endpoint conditions.

There is still a diagonal convention hidden in (2). If positive time is required and \(x=y\) is included, the formula is false even for the free particle on a circle. The mathematically viable version studied below is therefore:

\[\mathcal R_{\ne}(h):\qquad \text{every ordered pair }x,y\in\widetilde M,\ x\ne y, \text{ is joined in positive time by an orbit of exact energy }h. \tag{3} \]

Equivalently, one may keep \(x=y\) but declare the diagonal condition vacuous. This is not a silent rewriting of the source: (1), (2), the projected-endpoint reading of (1), and (3) are recorded as distinct formulations.

11824 | AIM-PDES-0090

Five Mane-critical questions and stability of a full Aubry graph

P / partially_solved | AIM 研讨会问题汇编

1. **Problem 16 (aperiodic levels).** For a compact manifold \(M\) and a Tonelli Lagrangian \(L:TM\to\mathbb R\), the horocycle-type example at the universal-cover Mañé critical value \(c_u\) was described as the only known energy level \(\{H=c_u\}\) having neither periodic orbits nor singularities. Does such a regular aperiodic level occur at another energy? 2. **Problem 17 (contact in the lower gap).** For a Tonelli Hamiltonian \(H:T^*M\to\mathbb R\), put \(\Sigma_h=H^{-1}(h)\), let \(c_u\) be the universal-cover critical value, and \[e_0=\min\{h\in\mathbb R:\pi(\Sigma_h)=M\}. \] If \(M\ne\mathbb T^2\), is every \(\Sigma_h\) with \(e_0<h<c_u\) not of contact type? 3. **Problem 18 (noncompact weak KAM boundary).** For a complete noncompact Tonelli system, understand the geometry of Contreras's compactification of \(M/d_c\) by an extended Aubry/static set represented by Busemann weak KAM solutions. 4. **Problem 19 (capacity of a lifted sublevel).** For a \(\mathbb Z^n\)-periodic Tonelli Hamiltonian on \(\mathbb T^n\times\mathbb R^n\), with \(c_0=\alpha(0)\), does the open lifted sublevel \[\{(x,p)\in\mathbb R^{2n}:H(x,p)<h\} \] have finite symplectic capacity for every \(h<c_0\)? 5. **Problem 20 (cohomological gradient stability).** Suppose \(H:\mathbb T^n\times\mathbb R^n\to\mathbb R\) is Tonelli, \(\pi(\mathcal A_0)=\mathbb T^n\), and \(H(x,Du)=\alpha(0)\) has a unique viscosity solution modulo constants. Define \[H_c(x,p)=H(x,p-c),\qquad H_c(x,Dv_c)=\alpha(c). \] Is \[\lim_{|c|\to0}\|Dv_c-Du\|_{\operatorname{Lip}(\pi(\mathcal A_c))}=0? \]

The source itself uses \(\operatorname{Lip}(\pi(\mathcal A_c))\), but does not define whether this is the full Lipschitz norm or only the uniform fiber norm of the Aubry graph. Both readings are distinguished below.

Focusing spherical shocks: similarity norms and gauge modes

P / partially_solved | AIM 研讨会问题汇编

Open Problem: A classical and apparently very hard problem is the analysis of non stationary spherical waves, e.g. a focusing inviscid shock (c.f. R. Courant & K.O. Friedrichs, *Supersonic Flow and Shock Waves*, Interscience Publishers, New York, (1948) or L.D. Landau & E.M. Lifshitz *Fluid Mechanics*, Pergamon Press, Oxford (1959)) Are such waves stable?

The original first page contains the following complete problem under S. Benzoni-Gavage, H. K. Jenssen, and M. Williams:

Szmolyan: (Kinetic and Boltzmann Equations)” and the kinetic equation that follow are the next presenter’s setup on page 2. They are not part of AIM-PDES-0051. The recovered statement studied here is therefore only the focusing-inviscid-shock question above. No mathematical symbols are missing from that question.

The phrase “such waves” is broad. To obtain a precise object, most of the literature studies the spherical, strong-shock, ideal-perfect-gas, self-similar Guderley solution. Results for that model do not automatically answer the question for finite-strength shocks, nonideal equations of state, nonsimilar focusing waves, or viscous flows.

Geometric Hydrodynamics in Open Problems - Problem 14

O / open | AMR 问题清单汇编

The concept of GM-flows appears closely related to the ``ancient flows" for the Navier--Stokes equations but, in fact, it is different. Both concepts express the general idea that, in reality, we observe flows that have existed since long time ago (one may imagine a river flow). In this regard, it is not natural to consider flows starting at some definite time t_0 with some (arbitrary) initial velocity u_0. GM-flows have natural, intrinsic structure (analytic level lines of vorticity) and some natural, finite regularity in the transversal direction. The question of which functional classes are suitable for their study is an intriguing open problem.

Determine the true regularity of GM-flows in the framework of anisotropic function spaces.

Geometric Hydrodynamics in Open Problems - Problem 18 (Aging Problem)

O / open | AMR 问题清单汇编

Consider an arbitrary solution $u=u(t,x)$ of the Euler equations in M. Given any two time instants can one decide which velocity field $u(t_1,x)$ or $u(t_2,x)$ corresponds to an earlier time instant? In other words, is it possible to determine the aging of the fluid from its velocity field? Numerical experiments suggest that fluids ``age" with time: starting with a smooth initial velocity $u_0(x)$ the corresponding solution becomes ``wrinkled" in that its derivatives generally grow. (V. Yudovich referred to this phenomenon as ``regularity deterioration".)

Is it possible to quantify the ``aging" property of the fluid?

Geometric Hydrodynamics in Open Problems - Problem 2

O / open | AMR 问题清单汇编

It turned out that in all of the above cases the corresponding configuration space has a natural groupoid structure. Using the corresponding Lie groupoids of multiphase diffeomorphisms instead of the Lie group of volume-preserving transformations in Arnold's setting one can describe the corresponding Lie algebroids and obtain geometric and Hamiltonian interpretations for the motion of the corresponding multiphase fluids, ``homogenized" vortex sheets, and generalized flows. Solutions of the above Euler equations were proved to be precisely the geodesics of an L^2-type right-invariant (source-wise) metric on the corresponding Lie groupoids of multiphase volume-preserving diffeomorphisms [IK18, IK22]. Another interesting domain for applications of Lie groupoids is provided by elasticity theory, cf. [mar-hugh, Kupf, JimLeon].

Extend the geodesic and Hamiltonian descriptions of the Euler-Arnold equations on Lie groupoids to problems of elasticity theory.

O / open | AMR 问题清单汇编

Arnold pointed out the remarkable topology of steady 3D fields: for an analytic steady field, not everywhere collinear with its curl, the flow domain is almost everywhere fibered into invariant tori and annuli, see [arn66, ak]. If the steady field is everywhere collinear with its vorticity but the proportionality coefficient is a generic function, then the domain is still fibered in a similar way. If the steady field is Beltrami, i.e., it is an eigenfield for the curl operator, $\mathrm{curl} v=\lambda v$, then its topology can be very intricate. Hence a paradox arises: a generic steady field has a very regular topology, while a sufficiently chaotic field must necessarily be an eigenfield for the curl operator.

Explain this paradox: what is a typical steady field and what genericity notion is natural for steady fields?

Geometric description of vortex sheets leads to an interesting non-local metric of hydrodynamical pedigree on shape spaces: it is an $H^{-1/2}$-metric on closed hypersurfaces bounding the same volume (or equivalently, on constant densities inside those hypersurfaces), see [IK18]. Such a metric is constructed with the help of the Neumann-to-Dirichlet operators and it is always nondegenerate since it is bounded below by the Kantorovich--Wasserstein distance. Geodesics with respect to this metric describe motions of potential fluid flows with vortex sheets and fluids with free dynamic boundary, cf. [IK18, Marsden, Loe].

Describe the differential geometry of shape spaces equipped with such $H^{-1/2}$-metrics obtained as metrics on dynamic boundaries or vortex sheets.

Now, the next natural question concerns what happens with the energy that has escaped from the system? One can introduce the ``limit absorption principle'' for our system. Namely, one can introduce a friction for the balls of the family F_N which absorbs the energy and then let N go to infinity. But this solution is not completely legitimate as here the energy sink is included from the beginning and it is only moved farther and farther away. So, this explanation of the energy escape is circular.

Is there a more natural way to introduce energy dissipation without explicit introduction of a friction mechanism?

Hamilton-Jacobi graph regularity versus KAM conjugacy

P / partially_solved | AIM 研讨会问题汇编

The existence of KAM invariant tori of a Hamiltonian system on \(\mathbb T^n\times\mathbb R^n\) is equivalent to the existence of regular solutions of the Hamilton--Jacobi equation \[H(x,c+Du(x))=\alpha(c). \] Hence KAM theory can be regarded as regularity result for viscosity solutions. Question: Is it possible to obtain proofs of KAM results using this connection?

Open Problems for Painleve Equations - Problem 1

O / open | AMR 问题清单汇编

\quad

\itemsep=0pt

- The Runge--Kutta method, and variants, are standard ODE solvers. Can we do better for integrable equations such as the Painlev\'e equations?

- Painlev\'e equations are ``integrable" and solvable by the isomonodromy method through an associated Riemann--Hilbert problem. How can we use this in the development of software for studying the Painlev\'e equations numerically?

- It is well known that there are {discrete Painlev\'e equations}, which are integrable discrete equations that tend to the associated Painlev\'e equations in an appropriate continuum limit. Should we use a ``integrable discretization" of the Painlev\'e equations?

背景链接：https://arxiv.org/abs/1901.10122

11960 | AMR-151-0002

Open Problems for Painleve Equations - Problem 2

O / open | AMR 问题清单汇编

The Painlev\'e equations are known to have a cornucopia of properties such as: a Hamiltonian representation; exact solutions (rational solutions, algebraic solutions, solutions in terms of classical special solutions); B\"acklund transformations (which relate two solutions of a Painlev\'e equation); associated isomonodromy problems (which are Lax pairs that express the Painlev\'e equation as the compatibility of two linear systems); and asymptotic approximations in the complex plane, with associated connection formulae relating the asymptotics. For details see [refPAC05review,refConte,refFIKN,refGLS,refIKSY,refKNY,refNoumi] and the references therein.

A complete classification and a unifying structure for these properties is needed as the presently known results are rather fragmentary and non-systematic.

11978 | AIM-PDES-0077

Quadratic-chain characterization of the Aubry set

P / partially_solved | AIM 研讨会问题汇编

The primary AIM PDF was checked directly. With typographical layout normalized, it asks about \[L_f(x,v)=\frac12\lVert v-f(x)\rVert_x^2 \] for a smooth vector field \(f\) on a compact Riemannian manifold \(M\), the relation between its zero-class Aubry set and recurrence of the flow \(\phi^t\) of \(f\), and uniqueness of the zero solution of a stationary Hamilton--Jacobi equation. The PDF literally says that the zero section in \(TM\) is invariant and literally prints \[H_-(x,p)=\frac12\lVert p\rVert_x^2-p(f(x)). \]

There are three independent formulation defects.

1. In standard tangent-bundle coordinates the invariant copy of the \(f\)-flow is \(\operatorname{Graph}(f)=\{(x,f(x)):x\in M\}\), not the zero section. It is this graph that the Legendre transform sends to the zero section of \(T^*M\). 2. The Legendre transform of the displayed \(L_f\) is \[H_+(x,p)=\frac12\lVert p\rVert_x^2+p(f(x)), \] since \(p=(v-f)^\flat\). The printed \(H_-\) is instead dual to \(L_{-f}(x,v)=\frac12\lVert v+f(x)\rVert^2\), the Mañé Lagrangian for the reversed vector field. 3. A stationary Hamilton--Jacobi equation is invariant under \(u\mapsto u+C\). Thus \(u=0\) is never literally the unique solution on a nonempty \(M\). On connected \(M\), the meaningful question is uniqueness modulo constants, or uniqueness after imposing \(u(x_*)=0\).

The PDF's \(H1(M,\mathbb R)\) should also be read as \(H^1(M,\mathbb R)\). None of these corrections is silently substituted for the source: below, \(L_f,H_+\) are the consistent formulation, and the printed minus-sign equation is handled separately by time reversal.

I assume henceforth that \(M\) is compact, connected, without boundary, and Riemannian, and that \(f\) is smooth. Write \(\mathcal A_f\subset M\) for the **projected** zero-class Aubry set and \(\widetilde{\mathcal A}_f\subset TM\) for the tangent-bundle Aubry set.

11979 | AIM-PDES-0032

Quadratic-growth complex Monge-Ampere rigidity with a completeness gap

P / partially_solved | AIM 研讨会问题汇编

Let \(u\) be plurisubharmonic solution to \[\det(u_{\bar k j})=1\quad\hbox{on }\mathbb C^n \] satisfying \[C^{-1}(|z|^2+1)\leq u\leq C(|z|^2+1), \] then \(u\) is quadratic.

The reversal \(u_{\bar k j}\) versus the more usual \(u_{j\bar k}\) is harmless. There are, however, three source-level ambiguities or omissions:

1. no regularity or solution concept is specified (classical, viscosity, or pluripotential); 2. it is not said whether the displayed inequalities hold everywhere or only outside a compact set; 3. completeness of the Kähler metric defined by the complex Hessian is not assumed.

The AIM record also says that An-Min Li and Li Sheng solved the problem. Their theorem has extra smoothness and completeness hypotheses, so that remark is correct only for the strengthened reading recorded in Section 2 below.

Throughout the elementary arguments here, \[\partial_{z_j}=\tfrac12(\partial_{x_j}-i\partial_{y_j}),\qquad \partial_{\bar z_j}=\tfrac12(\partial_{x_j}+i\partial_{y_j}). \] Thus \(u_{z\bar z}=\frac14\Delta u\) in complex dimension one.

11982 | AIM-PDES-0099

Quantizing Mather measures by equilibrium packets and smooth-graph WKB states

P / partially_solved | AIM 研讨会问题汇编

Consider the Hamiltonian \[H(x,p)=\frac12|p|^2+V(x), \] where \(V\) is periodic on \(\mathbb T^n\). The corresponding quantum Hamiltonian is \[-\frac{h^2}{2}\Delta+V(x). \] Do Mather sets play a role in the semiclassical limit? Conversely, can one “quantize” Mather sets by building corresponding quasimodes with good error bounds? Would a Diophantine condition be useful?

It is Craig Evans's problem from the AIM workshop *New connections between dynamical systems and PDE's*.

The mathematical text recovered from the original AIM page is:

Immediately after identifying the operator as \(-h^2\Delta/2+V\), the source displays the eigenproblem with \(+h^2\Delta u/2+Vu=Eu\). With the analytic convention \(\Delta=\sum_j\partial_{x_j}^2\), the quantization of the stated symbol \(|p|^2/2+V\) is \[P_h=-\frac{h^2}{2}\Delta+V. \] That is the operator treated below. The plus-sign display would instead have principal symbol \(-|p|^2/2+V\), which is not the stated Tonelli Hamiltonian.

Quenched Brownian large deviations in stationary ergodic potentials without mixing

P / partially_solved | AIM 研讨会问题汇编

33. (Elena Kosygina) Let \(\Omega\) be a probability space with probability measure \(P\) ergodic under a shift transformation group \(\tau_x:\Omega\to\Omega\), \(x\in\mathbb R^n\). Consider the stochastic Hamilton--Jacobi equation \[u_t+H(D_xu,\tau_x\omega)=0,\qquad (x,t)\in\mathbb R^n\times(0,\infty), \] where \(H(p,\omega)\) is convex in \(p\) and satisfies some regularity assumptions, for example \[H(p,\omega)=\frac12|p|^2-V(\omega). \] A homogenization result for this problem was obtained by Lions and Souganidis. For the Hamiltonian above homogenization is equivalent to a large deviation result for Brownian motion among random obstacles (Snitzman). Problem: Derive a large deviation result for general stationary ergodic setting without any independence or mixing assumptions on \(P\) under the shifts.

11987 | AIM-PDES-0047

Recovered HCF+ and a complete curve-case continuation and entropy theorem

P / partially_solved | AIM 研讨会问题汇编

Can the Streets--Tian continuation criterion for \(HCF_+\) be reduced to control of fewer geometric quantities, and does this exact flow possess Perelman-type \(\mathcal F\) and \(\mathcal W\) functionals?

about a flow of inverse Hermitian metrics and displays \[\frac{\partial}{\partial t}g^{j\bar k} =g^{m\bar n}\partial_m\partial_{\bar n}g^{j\bar k} -\partial_m g^{j\bar k}\,\partial_{\bar n}g^{m\bar k}. \tag{bad} \] It then states the known finite-time obstruction \[|\mathrm{Rm}^{\mathcal{Ch}}|+|T|+|\nabla T|\longrightarrow\infty \] and asks whether this can be improved and whether analogues of Perelman's \(\mathcal F\) and \(\mathcal W\) functionals exist.

Equation (bad) is not a tensor equation under the Einstein convention. In its quadratic term, \(\bar n\) occurs only once while the supposedly free index \(\bar k\) occurs twice. Therefore the literal displayed equation cannot be analyzed as a geometric flow.

The intended equation is independently verified by Proposition 3.9 and Corollary 3.10 of Ustinovskiy's 2018 Princeton thesis. The recovered inverse-metric equation is \[\boxed{\quad \frac{\partial}{\partial t}g^{i\bar j} =g^{m\bar n}\partial_m\partial_{\bar n}g^{i\bar j} -\bigl(\partial_m g^{i\bar n}\bigr) \bigl(\partial_{\bar n}g^{m\bar j}\bigr). \quad} \tag{HCF\(_+^{-1}\)} \] Thus the first \(g^{j\bar k}\) in the bad quadratic term must be \(g^{j\bar n}\). All contracted and free indices then occur correctly.

Invariantly, this is Ustinovskiy's distinguished Hermitian curvature flow, now often called the **positive Hermitian curvature flow** \(HCF_+\): \[\frac{\partial}{\partial t}g_{i\bar j} =-\Theta_{i\bar j},\qquad \Theta_{i\bar j}=S^{(2)}_{i\bar j}+\frac12Q^2_{i\bar j}, \tag{HCF\(_+\)} \] where \[S^{(2)}_{i\bar j}=g^{m\bar n}\Omega_{m\bar n i\bar j},\qquad Q^2_{i\bar j} =g^{m\bar n}g^{p\bar s}T_{pm\bar j}T_{\bar s\bar n i}. \] Here \(\Omega=\mathrm{Rm}^{\mathcal{Ch}}\) and \(T\) are respectively the curvature and torsion of the Chern connection. The recovered problem is:

Scattering for the Quintic Resonant System

P / partially_solved | Oberwolfach 报告问题汇编

别名：Duplicate Quintic Resonant-System Scattering Problem [OWR-11788-005]

For a sequence $\vec u=(u_j)_{j\in\mathbb Z^2}$ governed by the quintic resonant system

$$i\partial_tu_j+\partial_{xx}u_j=\sum_{(j_1,\ldots,j_5)\in\mathcal R(j)}u_{j_1}\overline{u}_{j_2}u_{j_3}\overline{u}_{j_4}u_{j_5},$$

where

$$\mathcal R(j)=\left\{(j_1,\ldots,j_5)\in(\mathbb Z^2)^5:\ j_1-j_2+j_3-j_4+j_5=j,\ |j_1|^2-|j_2|^2+|j_3|^2-|j_4|^2+|j_5|^2=|j|^2\right\},$$

define

$$E_{\mathrm{ls}}(\vec u)=\frac12\sum_{j\in\mathbb Z^2}\langle j\rangle^2\lVert u_j\rVert_{L^2(\mathbb R)}^2.$$

For every $E>0$ and every smooth initial datum with $E_{\mathrm{ls}}(\vec u_0)\leq E$, does there exist a global solution conserving E_{ls} that scatters as $t\to\pm\infty$?

Smooth periodic bounded-gradient minimizers need not be Birkhoff

S / solved | AIM 研讨会问题汇编

If \(u\) is minimal and \(\sup_{\mathbb R^n}|Du|<\infty\), must the projection of \(\operatorname{graph}u\) to \(\mathbb T^{n+1}\) have no self-intersections?

Let \[L:\mathbb T^n\times\mathbb T\times\mathbb R^n\longrightarrow\mathbb R, \qquad L=L(x,u,p), \] be smooth and satisfy the usual convexity assumptions in \(p\). A model is \[L(x,u,p)=\frac12|p|^2+F(x,u), \] where \(F:\mathbb T^{n+1}\to\mathbb R\) is periodic in all variables. A function \(u:\mathbb R^n\to\mathbb R\) is *minimal* if it minimizes the action against every compactly supported variation. Is there an analytic condition guaranteeing that a minimal graph has no self-intersections on the torus? More concretely:

The phrase “without self-intersections” is not the tautological assertion that an ordinary graph in \(\mathbb R^{n+1}\) is embedded. For \(k=(m,\ell)\in\mathbb Z^n\times\mathbb Z\), set \[(T_k u)(x)=u(x+m)+\ell . \] Bangert's definition is that the orbit \(\{T_k u\}\) is totally ordered pointwise: for every \(k\), either \(T_k u\ge u\) everywhere or \(T_k u\le u\) everywhere (with the strong maximum principle refining this to strict inequality or equality). Equivalently, integer translates of the graph are disjoint or identical. This is also called the Birkhoff property.

Static-class criterion for generic Hamilton-Jacobi uniqueness

P / partially_solved | AIM 研讨会问题汇编

4. (Albert Fathi) Is it true that for generic \(L\in C^\infty\) there exists only a one-parameter family of viscosity solutions of the corresponding Hamilton-Jacobi equation?

The sentence is not self-contained. The preceding item supplies the intended weak-KAM setting: \(M\) is compact; \(L:\mathbb T\times TM\to\mathbb R\) is a smooth time-periodic Lagrangian satisfying the usual Mather assumptions (strict fiberwise convexity, superlinearity, and completeness); and one works at a cohomology class \(c\). The autonomous convention \(\mathbb T=\{0\}\) is included in the same formalism. If \(\eta_c\) is a closed one-form representing \(c\), the critical equation is

\[u_t+H(t,x,\eta_c(x)+D_xu)=\alpha_L(c) \tag{HJ}_{L,c} \]

on \(\mathbb R/\mathbb Z\times M\); in the autonomous case it is

\[H(x,\eta_c(x)+Du)=\alpha_L(c). \]

Adding a constant to a solution produces another solution. Thus “only a one-parameter family” is recovered as **uniqueness modulo additive constants**, or equivalently uniqueness after a normalization such as \(u(z_0)=0\).

The source does not say whether “generic” means a residual subset of the full space of Tonelli Lagrangians or Mañé genericity under smooth potential perturbations, and it does not quantify over \(c\). These distinctions matter. The standard theorem recovered below uses: a fixed strong Tonelli Lagrangian \(L_0\), a fixed class \(c\), and a residual set of potentials \(f\in C^\infty(\mathbb T\times M)\) in the \(C^\infty\) Fréchet topology, applied to \(L_0-f\). No conclusion for every uncountably many \(c\) is silently inserted.

12063 | AIM-PDES-0049

Stationary spherical shocks: annular existence and center compatibility

P / partially_solved | AIM 研讨会问题汇编

The record comes from the problem list *Open Problems in Multidimensional Stability of Waves and Patterns*, compiled by N. Costanzino after the AIM workshop of May 16--20, 2005. In space dimension \(d=2\) or \(3\), put \(m=d-1\), write the density as \(\rho(r,t)\), and take the velocity vector to be \(u(r,t)x/r\). The displayed barotropic system is

\[\rho_t+(\rho u)_r+\frac{m\rho u}{r}=s(r,t), \] \[(\rho u)_t+(\rho u^2+P(\rho))_r+\frac{m\rho u^2}{r} =\nu\left(u_r+\frac{mu}{r}\right)_r+F(r,t). \tag{1} \]

Here \(s\) and \(F\) are the mass and momentum sources. The displayed setup uses uppercase \(F\), while the question later calls the same momentum source lowercase \(f\). This report uses \(F\); it is a notation inconsistency in the source, not a mathematical distinction.

The recovered question asks whether (1) has stationary spherical viscous or inviscid shocks, how \(s\) and \(F\) must be chosen, whether either may vanish, how curvature affects stability and nearby nonspherical fronts, and whether stability can change when the radius crosses a critical value \(r_*\).

12074 | AIM-PDES-0092

Tensorization of white-noise hyperbolic minimizers

P / partially_solved | AIM 研讨会问题汇编

\[L(x,v,t)=L_0(x,v)+\sum_{i=1}^{N}F_i(x)\dot w_i(t) \quad\text{on }\mathbb T^n\times\mathbb R^n, \tag{1} \]

where the \(w_i\) are independent Brownian motions. It assumes that a forcing map is an embedding, states that almost surely there is a unique global minimizer, and conjectures that this minimizer is a hyperbolic trajectory of the Lagrangian flow. It notes that E, Khanin, Mazel, and Sinai proved the assertion for \(n=1\).

1. The PDF prints \(F=(F_1,\ldots,F_n):\mathbb T^n\to\mathbb R^N\), although (1) contains \(N\) functions. The type-correct and standard reading is \[F=(F_1,\ldots,F_N):\mathbb T^n\longrightarrow\mathbb R^N. \tag{2} \] This is the embedding condition used in the later random Hamilton--Jacobi literature. 2. It prints \(\gamma:\mathbb R\to M\), but no \(M\) is introduced. The configuration space in the problem is \(\mathbb T^n\), so the intended codomain is \(\mathbb T^n\).

The words “positive definite” are understood in the usual Tonelli sense of positive-definite velocity Hessian, not as pointwise positivity of the value of \(L_0\).

Because \(\dot w_i\) is distribution-valued, (1) is not an ordinary time-dependent function. For an absolutely continuous competitor \(\gamma\) on \([s,t]\), the stochastic action is read pathwise as

\[A^\omega_{s,t}(\gamma) =\int_s^t L_0(\gamma,\dot\gamma)\,du +\sum_i\int_s^t F_i(\gamma(u))\,dw_i(u), \tag{3} \]

with the last integral defined by integration by parts:

\[\int_s^t F_i(\gamma)\,dw_i =F_i(\gamma(t))w_i(t)-F_i(\gamma(s))w_i(s) -\int_s^t w_i(u)\,d(F_i\circ\gamma)(u). \tag{4} \]

This is pathwise well defined because \(F_i\circ\gamma\) is absolutely continuous. A two-sided global minimizer is a curve every compact segment of which minimizes (3) among curves with the same endpoints.

Here “hyperbolic” is taken in the random-dynamical sense used in the later work: the derivative cocycle along the global minimizer has no zero Lyapunov exponent, equivalently in this symplectic setting it has \(n\) stable and \(n\) unstable directions with exponential rates in the tempered/nonuniform sense. Where uniform exponential-dichotomy estimates are available, the product result below preserves those as well.

12075 | AIM-PDES-0060

The differentiated Benjamin--Ono spectral problem

P / partially_solved | AIM 研讨会问题汇编

Setup. Consider the Benjamin--Ono equation \[u_t+u u_x-Ku_x=0, \qquad \widehat{Ku}(k)=|k|\widehat u(k). \] This equation supports travelling waves of the form \[\phi(z)=\frac{4}{1+z^2}. \] The resulting eigenvalue problem is \[(cv+Kv-\phi v)_z=\lambda v. \tag{A} \]

Open Problem. What is the spectrum of (A) and how does it relate to the spectrum of \[cv+Kv-\phi v=\lambda v, \] which is well known. A possible approach would be to treat the eigenvalue equation as a two dimensional problem.

The PDF confirms the coefficient \(4/(1+z^2)\), the multiplier \(|k|\), and the derivative outside the full parenthesis in (A). The K. Zumbrun material on strong viscous shocks starts the next presenter and is not part of this problem.

It is useful to restore the speed parameter:

\[\phi_c(x)=\frac{4c}{1+c^2x^2},\qquad c>0. \]

At \(c=1\) this is the profile printed in the AIM source. Throughout this report \(D=|D|\) denotes the Fourier multiplier \(|\xi|\), and

\[L_c=D+c-\phi_c,\qquad A_c=\partial_xL_c. \tag{1.1} \]

The spectral parameter for \(A_c\) is denoted by \(\lambda\); a selfadjoint spectral parameter for \(L_c\) is denoted by \(\mu\). This prevents the two different eigenvalue problems from being conflated.

12077 | AIM-PDES-0028

The refuted C1 conjecture and radial rigidity

S / solved | AIM 研讨会问题汇编

A function \(u:\Omega\to\mathbb R\) satisfies the special Lagrangian equation if \[\sum_i\arctan(\lambda_i)=c, \] where \(c\) is constant and the \(\lambda_i\) are the eigenvalues of \(D^2u\). (Conjecture of Nadirashvili--Vlăduț) Any viscosity solution on the unit ball is \(C^1(B)\) for sufficiently smooth boundary data.

The original paper states the conjecture as follows: any *Harvey--Lawson solution* of \(\mathrm{SLE}_\theta\) on a ball \(B\) lies in \(C^1(B)\), provided the boundary value \(\varphi\) is sufficiently smooth [NV10, p. 1180]. The original statement does not specify a Hölder/Sobolev threshold for “sufficiently smooth.” It is a branchwise Dirichlet statement; the middle branch in dimension three was the motivating nonconcave case.

For the analysis below, the recovered equation is \[F(D^2u):=\operatorname{tr}\arctan(D^2u) =\sum_{j=1}^n\arctan\lambda_j(D^2u)=c, \qquad c\in(-n\pi/2,n\pi/2), \tag{SLE} \] with every arctangent on its principal branch. “\(C^1(B)\)” is read as interior \(C^1\) regularity.

12079 | AIM-PDES-0041

The solved J-equation criterion and a sharp chamber on the one-point blow-up

P / partially_solved | AIM 研讨会问题汇编

The displayed mathematics agrees with Lejmi--Székelyhidi's original formulation.

The recovered statement is the following. Let \(M\) be a compact Kähler manifold of complex dimension \(n\), let \(\omega,\chi\) be Kähler forms, and set

\[\omega_\varphi=\omega+\sqrt{-1}\,\partial\bar\partial\varphi>0, \qquad c=n\frac{[\omega]^{n-1}\cdot[\chi]}{[\omega]^n}. \]

Determine whether

\[\operatorname{tr}_{\omega_\varphi}\chi=c \]

has a smooth solution exactly when, for every irreducible proper analytic subvariety \(V\subset M\) of complex dimension \(p\), where \(1\le p\le n-1\),

\[\int_V\left(c\,\omega^p-p\,\omega^{p-1}\wedge\chi\right)>0. \tag{LS} \]

For singular \(V\), the integral means pairing the closed form with the integration current \([V]\), equivalently integration after resolution. It depends only on the Kähler classes. Reducible subvarieties add no conditions beyond their irreducible components. The source phrase “all proper subvarieties” is conventionally restricted to positive dimensions \(1,\ldots,n-1\); zero-dimensional sets do not supply a J-positivity obstruction.

12116 | AIM-PDES-0007

Weighted convection cancellation for topographic geostrophic profiles

P / partially_solved | AIM 研讨会问题汇编

The QG equation with Ekman layer with topography

It gives no equation, domain, quantifiers, remarks, or bibliography. Consequently there is no uniquely verified mathematical statement to solve. In particular, “QG” may mean the three-dimensional quasi-geostrophic system with Ekman pumping, surface QG, a barotropic potential-vorticity model, or a quasi-geostrophic limit of a rotating primitive model. These are not interchangeable.

The following is therefore a **closely matching modern formulation**, not a claimed transcription of the intended AIM problem. Chemin, Fanelli, and Gallagher study a rapidly rotating incompressible fluid in

$$ \Omega_H=\{(x_h,z):x_h\in O,\ -H(x_h)<z<0\}, \qquad H(x_h)=\varphi(\rho(x_h)), $$

where (ρ) is the distance from a smooth convex island (after a shore cutoff), $(|\nabla_h\rho|=1)$, and the isobaths are parallel to the coast. Their Navier--Stokes--Coriolis system is

$$ \partial_tu_\varepsilon-\varepsilon\beta\Delta u_\varepsilon +\frac1\varepsilon e_3\times u_\varepsilon +(u_\varepsilon\cdot\nabla)u_\varepsilon =-\frac1\varepsilon\nabla p_\varepsilon, \qquad \nabla\cdot u_\varepsilon=0, \qquad u_\varepsilon|_{\partial\Omega_H}=0. \tag{NSC} $$

Here $(\beta>0)$ is fixed and the Rossby number $(\varepsilon\downarrow0)$. This model has precisely the three ingredients visible in the AIM title-geostrophic balance, Ekman boundary layers, and non-flat topography-but the available evidence does not prove that it is the intended model.

Sign convention: throughout this report,

$$ \nabla^\perp h=(-\partial_2h,\partial_1h), \qquad e_3\times(u_1,u_2,0)=(-u_2,u_1,0). $$

Reversing the orientation changes both tangential directions but not the orthogonality lemma or the positive damping rate below.

A full toric Kummer image on projective space with an exact cyclotomic correlation

P / partially_solved | AIM 研讨会问题汇编

Generalizing: Can you find an example in higher dimensions?

Find classes of examples of polynomials or rational maps \(d\geq3\) for which we can compute explicitly the arboreal Galois representation up to finite index over various fields.

This sentence is not self-contained.

It also suggests trying Stoll's techniques for \(x^p+c\). The archived section has no further introduction, so “generalizing” must at least carry forward the request for computable arboreal images. Since Problem 10.1 already varies the **degree** of a map of \(\mathbb P^1\), “higher dimensions” most naturally means a phase space of dimension greater than one. This is consistent with the official workshop report, where Joseph Silverman describes maps of \(\mathbb P^2\) as candidates for higher-dimensional arboreal representations.

Several choices nevertheless remain unstated:

* the phase space could be \(\mathbb P^r\), a product, an abelian variety, or a general quasiprojective variety; * a “preimage tree” is still a one-dimensional rooted graph, even when the phase space has dimension \(r>1\); * for an endomorphism of \(\mathbb P^r\), its algebraic degree and generic number of preimages differ: degree \(d\) gives topological degree \(d^r\); * “the expected group” could mean the full automorphism group of the regular preimage tree or the smaller group forced by algebraic structure.

We preserve these distinctions and give an honest endomorphism of \(\mathbb P^r\), not merely a self-map written on a Cartesian product. Its image is computed exactly. It is maximal in the natural toric Kummer comparison group, although it has infinite index in the full tree automorphism group.

12133 | AIM-DYNAMICAL_SYSTEMS-0036

A gcd law for dynatomic-field intersections

P / partially_solved | AIM 研讨会问题汇编

“Describe $K_n\cap K_{n'}$. Prove that this is small.”

It is problem 11.2 in the section “Formal period n” of the 2016 AIM workshop *The Galois theory of orbits in arithmetic dynamics*. The preceding record asks, “When is the image maximal?”, but neither record defines K_n. The workshop report confirms that dynatomic Galois groups were intended: Jones discusses Galois groups of fields generated by periodic points, and Krumm writes $\Phi_n(c,x)$ for the nth dynatomic polynomial of x^2+c and studies its splitting field over $\mathbb Q(c)$ [AIM16]. Still, the fragment does not say whether the map is generic or specialized, whether the base is a number field or function field, or whether K_n means the exact/formal-period field or the field of all points whose period divides n.

We use the following explicit reconstruction. Let K be a characteristic-zero field and $f\in K[x]$ have degree at least two. Define the dynatomic polynomial \[\Phi^*_{f,n}(x) =\prod_{r\mid n}\bigl(f^r(x)-x\bigr)^{\mu(n/r)}, \tag{1.1} \] which is a polynomial despite its quotient presentation. Let \[K_n(f/K)=\text{the splitting field over K of }\Phi^*_{f,n}(x). \tag{1.2} \] When repeated roots occur, “splitting field” means the field generated by the distinct roots. Roots can have formal period n but smaller exact period in parabolic cases [MP94, MS95]; this distinction is kept explicit. The question is meaningful for distinct n,n'. If $n=n'$, the intersection is tautologically K_n.

The proved slice below takes $f(x)=x^d$ over $\mathbb Q$, with d even. In this family all relevant polynomials are separable and formal period equals exact period. Moreover, the splitting field of $f^n(x)-x$ is the same field as (1.2), so the answer is insensitive to the second ambiguity above.

A modewise rotating-AR analogue for discrete-time stochastic reaction-diffusion systems

P / partially_solved | AIM 研讨会问题汇编

Its damaged displays recover as

\[\dot x=f(x,y),\qquad \dot y=g(x,y), \]

and, after linearization at the stable fixed point,

\[\begin{bmatrix}dx\\dy\end{bmatrix} =A\begin{bmatrix}x\\y\end{bmatrix}dt +\begin{bmatrix}\sigma _1\,dW_1\\ \sigma _2\,dW_2\end{bmatrix}. \]

On page 2 the same question is repeated as Problem 13 and followed by a separate fast/slow-systems question.

“A discrete time reaction diffusion equation” is not specified further: it could mean a coupled map lattice, a time discretization of an SPDE, an integrodifference equation, or a microscopic discrete-time population process. The result below therefore treats a clearly stated coupled-map lattice model. Other interpretations require changing the multiplier and noise covariance, but the modewise argument survives whenever a spatial eigenbasis diagonalizes both.

Algebraic path shifts for the power-map tower

P / partially_solved | AIM 研讨会问题汇编

Let k be a field, let $f\in k(z)$ have degree at least 2, and let t be transcendental. Put \[k_\infty=k\Bigl(\bigcup_{n\geq0}f^{-n}(t)\Bigr),\qquad L=k_\infty\cap\overline{k}, \] and $G_\infty=\operatorname{Gal}(k_\infty/k(t))$, $G_\infty^{\rm geom}=\operatorname{Gal}(k_\infty/L(t))$. Can one algebraically construct “nice paths” which give explicit wreath recursions for $G_\infty^{\rm geom}$? More precisely, for $z\in f^{-1}(t)$, can one find explicit, perhaps recursively described, endomorphisms of the tower sending t to z?

Its question is:

Four formulation points matter.

1. The symbol t should be an indeterminate over k, and all fields should be placed in a fixed algebraic closure of $k(t)$. 2. For a rational map, k_∞ is best read as the directed union of the splitting fields of $f^{\circ n}(X)=t$. 3. The final K_∞ in the source is evidently the same tower previously called k_∞. 4. Every member of $\operatorname{Gal}(k_\infty/L(t))$ fixes t. Therefore a map sending t to a nontrivial first preimage cannot be a deck transformation. The algebraic counterpart of a path must instead be an isomorphism of pointed towers or an automorphism of the abstract L-field which changes the distinguished subfield $L(t)$ to $L(z)$.

Separability is also necessary for a regular rooted preimage tree. The theorem below assumes $\operatorname{char}L\nmid d$.

\[\dot x=f(x,y),\qquad \dot y=g(x,y), \tag{1.1} \]

and, after linearization at the stable fixed point,

\[\begin{bmatrix}dx\\dy\end{bmatrix} =A\begin{bmatrix}x\\y\end{bmatrix}dt +\begin{bmatrix}\sigma _1\,dW_1\\ \sigma _2\,dW_2\end{bmatrix}. \tag{1.2} \]

The source says that this process can be approximated by “a constant times a rotation times pair of standard indepen-dent Ornstein-Uhlenbeck processes” and asks for the analogue in a discrete-time reaction--diffusion equation and its connection to more general fast/slow systems. The PDF breaks “independent” at the end of a line, so `indepen-dent` is a typesetting line-break artifact.

The same equations and discrete-time question occur as Problem 1 on page 1. Problem 13 repeats them and adds, verbatim, “Also, what is the connection of this system to more general fast/slow systems?” That additional clause is the main focus of the new contribution below.

The source does not define the discrete-time reaction--diffusion model, the approximation parameter, or “fast/slow.” We therefore make three explicit choices:

- a discrete reaction--diffusion linearization is a noisy coupled map on a finite undirected graph; - its discrete Ornstein--Uhlenbeck analogue is a stable vector AR(1), or VAR(1), process; - a stable spatial mode can serve as a fast subsystem coupled to variables whose increments are of order \(\varepsilon\).

These are controlled interpretations, not claims that the AIM question has a unique model-independent answer.

Fix an ellipse with center O and foci f_1,f_2, and let $P=(P_i)_{i=1}^N$ range over its Poncelet family of N-periodic billiard orbits tangent to a fixed confocal caustic. Let P' be the outer polygon formed by consecutive tangent intersections and P'' the inner polygon of caustic tangency points; write A,A',A'' for their areas. The antipedal polygon of a polygon R with respect to M has sides through its vertices perpendicular to the corresponding R_i-M; A_M^*,C_0^*,C_2^* denote its area and centroids, with primes for $R=P'$. Prove that, for even N, $M=O,f_1,$ or f_2, the quantity the vertex centroid C_0^* is constant as P varies through the family. The source labels this assertion invariant code k_{405}.

Escape and conditional limits after eclipse pruning

P / partially_solved | AIM 研讨会问题汇编

Problem 11. Is there some limiting distribution and/or escape rate in the case that can be found in the case of eclipsing scatterers?

Open Problems and Questions: Tuesday

I inspected the text operators in the original AIM PDF. Two source issues are now resolved.

Two minimal grammatical repairs have the same apparent meaning:

- “Is there some limiting distribution and/or escape rate that can be found in the case of eclipsing scatterers?” - “Is there some limiting distribution and/or escape rate in the case of eclipsing scatterers?”

The source does not define the initial ensemble, the time variable (physical time or collision count), the random variable whose distribution should converge, or the admissible geometry. I use the standard open-systems interpretation: survival mass, a collision-count escape rate, and the distribution conditioned on survival.

For pairwise disjoint convex obstacles \(K_1,\ldots,K_q\subset\mathbb R^d\), the **no-eclipse condition** is \[\operatorname{conv}(K_i\cup K_j)\cap K_k=\varnothing \quad\text{for all distinct }i,j,k. \] “Eclipsing scatterers” means this condition fails: a third obstacle obstructs part, or sometimes all, of the line of sight between two others. Failure of no eclipse is not itself a dynamical model; different failures can cause symbolic pruning, grazing trapped rays, loss of compactness of the nongrazing trapped set, or none of these severe effects.

12385 | AIM-DYNAMICAL_SYSTEMS-0016

Exact prime-support endpoints over F_q(T)

P / partially_solved | AIM 研讨会问题汇编

Let $K=\mathbb F_q(T)$, let $f\in K(z)$ have degree at least two (or $f\in K[z]$ in the polynomial version), and let $\alpha\in K$. Replace rational primes by finite places of K. How large is the set of places dividing a nonzero numerator of some $f^n(\alpha)$? What analogues hold over other fields?

Taken literally, $f(z)\in\mathbb F_q(T)$ omits the variable in which f is iterated. The two preceding records remove the ambiguity. Problem 1.1 defines \[N(x)=\#\{p\le x:p\mid f^n(\alpha)\text{ for some }n\} \] and asks for its growth; Problem 1.2 asks how that growth differs for PCF and non-PCF maps. Accordingly, the minimal reconstruction of Problem 1.3 is:

For $K=\mathbb F_q(T)$ and a monic irreducible $P\in\mathbb F_q[T]$, write v_P for its normalized valuation. We use the degree cutoff \[\mathcal P_f(\alpha)=\{P:v_P(f^n(\alpha))>0 \text{ for some }n\ge0\text{ with }f^n(\alpha)\ne0\}, \qquad N_{f,\alpha}(D)=\#\{P\in\mathcal P_f(\alpha):\deg P\le D\}. \] The corresponding norm cutoff is $N_{f,\alpha}^{\rm norm}(X)= N_{f,\alpha}(\lfloor\log_qX\rfloor)$. Divisors of denominators instead measure visits to ∞, so numerator and denominator conventions must not be conflated.

Finite-relator detection of the free-subgroup cover property

P / partially_solved | AIM 研讨会问题汇编

Let A be a finite alphabet and Ω be a 2-sided subshift, i.e., a closed subset of $A^\mathbb{Z}$ that is invariant under the shift map σ. An element $g \in Homeo(\Omega)$ belong to the full group of the shift ($F(\Omega)$) if each point in Ω has an open neighborhood U such that $g|_U = (\sigma^n)|_U$ for some $n \in \mathbb{Z}$ depending on U is equal to resembles a power of the shift map.

Is it true that for all finitely generated subgroup $H \leq F(\Omega)$, H is either elementary amenable or for any K finitely presented subgroup such that $K \twoheadrightarrow H$, K contains a free subgroup?

Recovered question. Let $[[\sigma]]$ be the topological full group of (Ω,σ). Is every finitely generated subgroup $H\leq[[\sigma]]$ either elementary amenable, or does it have the property \[\mathcal C(H):\quad \text{every finitely presented group K admitting an epimorphism $K\twoheadrightarrow H$ contains a nonabelian free subgroup F_2?} \]

Finite-Time Invariant Manifolds and Unsteady Transport

O / open | Oberwolfach 报告问题汇编

Develop a theory of finite-time invariant manifolds that genuinely captures the time dependence of aperiodic unsteady flows. In particular, quantify transport created by intersecting or nonintersecting stable and unstable manifold segments and relate those manifolds to practical flow-barrier diagnostics.

12419 | AIM-DYNAMICAL_SYSTEMS-0001

Fixed-point proportions as boundary measure and a family approaching full Hausdorff dimension

P / partially_solved | AIM 研讨会问题汇编

It asks the following five broad questions after defining

\[\operatorname{FPP}(G)=\lim_{n\to\infty} \frac{\#\{g\in G_n:g\text{ fixes a vertex on level }n\}}{\#G_n}: \]

1. What can be said for groups acting on rooted trees? 2. On a fixed tree, can one find groups with nonzero fixed-point proportion and Hausdorff dimensions converging to (1)? 3. What can be said for iterated Galois groups? 4. What can be said for iterated monodromy groups of complex rational functions? 5. What can be said for complex polynomials that are not dynamically exceptional?

Three repairs are necessary before doing mathematics.

* The canonical JSON repeats the paragraph defining (k_n,G_n,G_\infty); the PDF has it only once. * The simultaneous phrases “(t\in k),” (G_n=\operatorname{Gal}(k_n/k(t))), and “(k=\mathbb C(t)) with (t) transcendental over (\mathbb C)” are inconsistent. In the generic formulation, (k) is the constant field, (t) is transcendental over (k), (K=k(t)), and (K_n=K(f^{-n}(t))) is the splitting field of (f^n(x)-t) (with the analogous numerator-minus-(t)-times-denominator polynomial for a rational map). Then (G_n=\operatorname{Gal}(K_n/K)). In the specialized formulation one instead chooses (a\in k), takes (K_n=k(f^{-n}(a))), and uses (\operatorname{Gal}(K_n/k)). * The cited identifier MR2162164 is Nekrashevych’s book [Nek05]. Proposition 6.4.2 says, for a **postcritically finite** complex rational function, that its profinite iterated monodromy group is the Galois group of the union of the generic splitting fields. The record’s citation arXiv:1204.2843 is Jones’s paper [Jon15], whose main dynamical theorem concerns postcritically finite **polynomials**, not arbitrary rational functions. A later rational-function theorem is [BJKL22], under additional hypotheses. Thus the record overstates both the scope of the book proposition and the Jones result.

The repaired generic setting will be used below. We assume the map is separable. Then a generic fiber of (f^n) has (d^n) distinct points, the preimage tree is the regular (d)-ary rooted tree, and the Galois action on all roots is faithful because those roots generate the splitting field. In positive characteristic these qualifications cannot be omitted: inseparability can destroy the regular tree.

Formal-period covers and the phase-quotient ramification budget

P / partially_solved | AIM 研讨会问题汇编

Fix d. If $n >>_d 1$, then is $M_d(n)$ of general type, where $M_d(n)$ marks periodic points of formal period n.

Known for abelian varieties and for $d=2$, $n=1,\ldots,5$ $M_d(n)$ is rational and $M_2(6)$ is general type (Blanc-Canci)

Its exact wording is:

The record adds, verbatim:

The notation $n\gg_d1$ is read as “all sufficiently large n, with threshold allowed to depend on d.”

There are two bibliographic corrections to the literature note. First, the small-period paper has three authors: Jérémy Blanc, Jung Kyu Canci, and Noam D. Elkies. Second, its theorem is stated for a point of **exact** period n, whereas Michelle Manes's $M_d(n)$ is constructed using **formal** period. Blanc--Canci--Elkies explicitly say that their exact-period variety is a PGL_2-invariant open subset of Manes's formal-period variety. Thus the birational assertions agree on the relevant component, but the moduli functors are not literally identical.

The abelian-variety analogy is broadly correct but too imprecise to be a citation. A precise modern result of Abramovich and Várilly-Alvarado says that for a locally closed $X\subset\mathcal A_g$, all irreducible components of its pullback to sufficiently high full-level moduli are of general type. Full abelian level structure is much richer than one marked dynamical periodic point, so this is an analogy rather than a reduction.
