人类数学猜想有多少？

规模评估与可追溯资料汇编

17,614

条已发布记录：编号、题名、完整问题表述与来源入口

17 个学科类别 / 1,117 条题名标记索引 / 1,417 条归档索引

中文评估 + 英文及 LaTeX 原始表述 + 可点击导航

检索日期：2026 年 10 月 25 日（Asia/Shanghai）

由中国跨学科学者 沈阳

124739259@qq.com

调度 AI 生成

严格的全球总数未知。本报告不把数据库条目数当作猜想总数。

01 结论：能数清什么，不能数清什么

目前无法给出“人类全部数学猜想”的可信精确总数，也无法证明一次搜集已经穷尽全部。可以严谨完成的是：明确计数口径，完整提取某个有边界的公开语料库，并把所有记录交给读者复核。

本次评估

问题	可支持的回答
人类历史上所有猜想，一共有多少个？	未知。未发表、已遗失、口头提出的猜想无法被完整观测；等价命题和猜想族也没有统一计数约定。
公开可检索的猜想与开放问题，大致多大？	数据库记录已达万至十万量级。这里说的是宽口径记录规模，不能解释为严格去重的未证猜想数量。
本报告实际收集了多少？	完整下载 19,031 条原始记录；逐条刊入其中 17,614 条 published=true 记录；另列 1,417 条归档记录索引。
标题明确含猜想类词语的有多少？	1,117 条标题命中 conjecture(s) 或 hypothesis/hypotheses。只是可重复的检索指标，不是严格猜想总数。
这些记录已经彻底去重了吗？	没有。ID 唯一；规范化表述后仍有 4 条冗余记录，得到 17,610 种文本。语义等价与变体尚未全面归并。

如果必须给一个数量级判断：广义、公开记录中的“猜想 + 开放问题 + 历史问题”已经是数万乃至接近十万条目的研究对象；对严格意义的“目前未解决、语义去重后的数学猜想”，本次证据不足以给出可靠区间。不要把 17,614、90,717 或二者之和称作人类猜想总数。[S1-S5]

这里没有用少数样本外推一个“精确全球数”，也没有将开放问题、形式化命题、定理和数据库记录混为一谈。

02 范围、定义与计数规则

猜想与开放问题

猜想通常是被提出并被认为可能成立、但尚未确立的数学断言。开放问题可以只是一个问题，甚至要求分类、构造、最优常数或算法；它未必包含被猜测为真的明确命题。两者有交集，不能互换。

历史猜想与当前猜想

已经被证明或被反驳的历史猜想仍可能保留名称。若“人类所有猜想”按历史口径统计，它们应保留；若问“尚待解决”，则必须区分已解决、部分解决、独立性、争议性声称等状态。

一个名称不一定是一个命题

广义黎曼猜想、标准猜想、Langlands 纲领等可以包含多个版本或命题族。一个猜想也可能有多个名称和等价形式。按名称计数、按论文中的编号计数、按逻辑等价类计数，会得到不同答案。

有限历史记录与潜在无限命题

人类在某个日期前实际写下的有限记录，不等于所有可以形式化表达的数学命题。参数族的无限多个实例也不应自动计为人类提出了无限多个独立猜想。

本报告的基本单位

采用数据集中的 problem_number 作为记录主键。published=true 的每条记录均保留，已解决记录也保留。published=false 记录仅进入归档索引，不计入 17,614。

“完整”的限定

本报告完整刊入所下载版本的 17,614 条已发布记录的 statement 字段；它是“该语料版本的完整汇编”，不是“数学史的完整全集”。没有对所有原论文逐页复核，也没有声称所有表述均正确、自足或仍未解决。

03 来源地图：不同数据库不能直接相加

来源	本次观察	计数对象与处理
UnsolvedMath v1.8.0 [S1-S2]	19,031 / 17,614	已下载原始 JSON 并自行计数；前者为全部记录，后者为 published=true。本报告的主体。
MathDB [S3]	90,717	网页显示的 problems 数量。涵盖多种知识条目和状态；全库下载需 API 订阅，本次未获取全库。
Erdős 社区库 [S4]	1,221	带固定编号的问题记录；已包含在 UnsolvedMath 主体中，不能再加一次。
Formal Conjectures [S5]	4,411	首页 Open 1,599 + Solved 2,812 的正式命题计数；页面另列教学、测试、API 类目，不能按总页面元素数量计猜想。
AIM / AMR [S6-S7]	目录型来源	原始研讨会问题及问题集入口；一个链接可包含很多问题。不是单条猜想登记册。
Kourovka Notebook [S8]	第 21 期	编者提供群论问题、历史答案与持续更新；语料库中的该集合有 1,934 条记录。
Clay 千禧年问题 [S9-S10]	7 个历史题目	一个经过筛选的著名问题集，不能代表整个数学界。三维庞加莱猜想已解决。

MathDB 的“90,717”是网页快照，不是本报告逐条验算的数。Formal Conjectures 中同一问题可能对应多个 formal statement；形式化表述存在，也不意味着该问题已有形式化证明。[S3,S5]

来源间高度重叠，抽取粒度和状态标准也不同，因此不能使用“各库数量相加”的方式估算全球总量。未观察到的部分也没有随机抽样概率，无法给出有统计意义的覆盖率或置信区间。

04 语料审计与可重复统计

指标	本次程序复核结果
下载文件 / 版本	problems.json / UnsolvedMath v1.8.0
原始记录总数	19,031
刊入正文的已发布记录	17,614
归档记录	1,417（重复记录和非问题摘录等，不全是重复猜想）
已发布记录的主键数	17,614 个唯一 problem_number；17,614 个唯一 id
空 statement 字段	0
标题完全相同的额外记录	121 条；同名不能直接认定数学内容重复
规范化后不同 statement 文本	17,610 种；仅做 Unicode NFKC 与空白合并
标题猜想关键词命中	1,117 条
直接 source_url 字段非空	10,381 条
source_url 缺失 / 空	7,233 条；尽量使用背景链接或问题集入口
已发布表述总长度	5,729,542 个字符（原始 statement 字段）

四组完全相同的表述

GEO-016 / GEOM-016；NT-041 / NUM-003；NT-047 / NUM-007；NT-049 / NUM-005。为保留与上游数据的一一对应关系，正文仍保留全部记录并加重复提示。

这只是文本去重，不会发现“表述不同但数学等价”的记录。例如不同语境下的同一问题、一个猜想的特殊情形、独立分问，都需要领域专家决定是否合并。

05 来源状态：15,332 条未完全解决标记

下列状态是 UnsolvedMath v1.8.0 的数据标签。open 与 partially_solved 合计 15,332 条，仅表示该数据快照未标为 solved，不能当作截至检索日仍未解决的独立猜想数。

open / 开放 8,283

partially_solved / 部分解决 7,049

solved / 已解决 2,282

题名命中子集	条数
open	574
partially_solved	462
solved	81
合计	1117

如何理解“已解决”

在问题汇编中，solved 可能包括被证明、被反驳或得到其他完整解答。它不保证原猜想为真。partially_solved 也可能覆盖部分情形、已报告但未经审定的结果等不同情况，不能从标签反推确定的数学结论。

状态证据的限制

17,614 条记录中，13,734 条没有专门的 status_review.evidence 字段；这不等于没有任何参考文献，但说明不能把一个统一的自动标签视作逐条专家认证。另有 538 条记录标记 unrefereed_claim。上游说明指出部分研究摘要和状态整理使用机器辅助；本报告不把这些摘要当作新定理。[S1]

Kourovka 编者明确说明：带有尚未得到数学家确认的 AI 解答的问题，仍应视为未解决。遇到重要结果，应回到原论文、编者更新和正式发表记录核验。[S8]

06 学科分布：本语料的覆盖形状

类别	记录数	占主体
数论 / Number Theory	1,657	9.4%
代数 / Algebra	1,003	5.7%
群论 / Group Theory	2,655	15.1%
代数几何 / Algebraic Geometry	1,159	6.6%
几何 / Geometry	1,854	10.5%
拓扑 / Topology	1,974	11.2%
分析 / Analysis	1,379	7.8%
偏微分方程 / Partial Differential Equations	438	2.5%
动力系统 / Dynamical Systems	888	5.0%
组合数学 / Combinatorics	1,032	5.9%
图论 / Graph Theory	1,181	6.7%
概率 / Probability	733	4.2%
集合论 / Set Theory	221	1.3%
逻辑 / Logic	374	2.1%
理论计算机科学 / Computer Science	554	3.1%
数学物理 / Mathematical Physics	363	2.1%
其他 / Miscellaneous	149	0.8%

学科类别沿用数据集的主分类，每条记录只在本表出现一次。现实中的问题可能跨学科。群论、拓扑与几何占比高，反映所选问题集的来源结构，不代表人类数学猜想的真实全球分布。

07 来源集合分布与别名恢复

语料所属集合	刊入条数
Oberwolfach 报告问题汇编	5,903
AMR 问题清单汇编	4,387
AIM 研讨会问题汇编	3,026
Kourovka 群论问题集	1,934
Erdős 问题	1,221
Open Problem Garden	377
Kirby 低维拓扑问题	366
独立 / 未分配集合	257
Ben Green 问题	81
DARPA 挑战	17
Hilbert 问题	14
Richard Guy 数论问题	10
Smale 问题	8
千禧年问题	6
Landau 问题	4
Hardy-Littlewood 猜想	3

这些是去归档后保留在各集合下的记录数。例如“Hilbert 的 23 个问题”在本语料中的所属集合只有 14 条，不能据此把历史上的 23 改写成 14；其他条目可能以别名或不同归属出现，也可能未覆盖。

别名案例：Collatz 猜想

NT-002 “Collatz Conjecture”在原数据中被归档，duplicate_of 指向 EP-1135。正文的 EP-1135 因而补充该别名。若只按标题搜 conjecture，会漏掉这个著名猜想。这直接说明 1,117 只是题名筛选结果，不是已收集猜想的完整数量。

08 阅读方式与重要边界

使用 PDF 书签可直接进入 17 个学科、题名索引或归档索引；全文可搜索英文名称、原始编号和 LaTeX 表达式。附录中的原始题名保留英文，避免自行翻译人名和专业术语造成新别名。

每条记录包含什么

依次为：本报告流水号与原始编号、题名、来源状态和集合、完整 statement 字段、可点击来源入口。可以恢复的归档别名也列在正文。编号用于定位，来源链接用于回查，二者都不代表本报告已验证题目的真伪。

公式为什么保留 LaTeX

各条表述中的 $...$、\frac、\forall 等以原有 LaTeX 文本显示，而非重新解释或自动改写为公式图片。这样保留括号、量词和上下标结构，便于复制检索。原始文本的断行会合并；排版使用的长短横线和少量兼容字形作显示规范化。PDF 内嵌数据附件保留原始字段。

来源入口的三种含义

“来源字段”来自原数据 source_url；“背景链接”是 background 字段中提取的首个网址，未逐条鉴别其优先级；“问题集入口 / 汇编入口”表示没有可直接采用的单条原始网址。链接可能失效，也可能只指向原始文献的一整页或一本问题集。

机器可读附件

本 PDF 内嵌 math_catalogue_data.zip，可由支持附件功能的 PDF 阅读器提取。它包含所有 19,031 条记录的选定原始字段、统计清单、17,614 条正文页码映射、归档关系和来源信息。部分浏览器预览不显示附件，但不影响阅读正文。

没有被穷尽的部分

付费文献、未数字化资料、未发表猜想、语言覆盖不足的资料、新产生的猜想，以及大型数据库里尚未取得的记录均可能遗漏。历史上已证明或反驳的猜想也没有得到系统全集覆盖。即使把一个语料库完整印出，仍不能声称收齐人类所有猜想。

09 著名问题导航与口径示例

以下是阅读导航，不另外增加主体记录数。概述仅用于区分计数类型；严谨条件与完整表述以原始来源为准。[S9-S11]

常见名称	正文主键
黎曼猜想	MPP-002
霍奇猜想	MPP-006
Birch-Swinnerton-Dyer 猜想	MPP-005
P 与 NP 问题	MPP-001
Navier-Stokes 存在性与光滑性	MPP-004
Yang-Mills 存在性与质量间隙	MPP-003
Collatz / 3n+1 猜想	EP-1135
强哥德巴赫猜想	LAN-001
孪生素数猜想	LAN-002
abc 猜想	NT-005
光滑四维庞加莱猜想	TOP-001

黎曼猜想：黎曼 ζ 函数的非平凡零点实部是否均为 1/2。

霍奇猜想：研究特定上同调类与代数循环之间的关系。

Birch-Swinnerton-Dyer 猜想：研究椭圆曲线的有理点秩与 L 函数在特定点的消失阶。

P 与 NP 问题：问 P 是否等于 NP；是开放问题，不能不加说明就称为一个取定方向的猜想。

Navier-Stokes 存在性与光滑性：具体方程与初值条件下的存在性、光滑性问题。

Yang-Mills 存在性与质量间隙：要求构造满足相应条件的量子理论并确立质量间隙。

Collatz / 3n+1 猜想：正整数按奇数 3n+1、偶数除以 2 迭代，猜测最终到达 1；原名在归档别名中。

历史对照：三维庞加莱猜想已经由 Perelman 解决，Clay 官方页有确认。[S10] 这份语料的 6 条 MPP 记录并不是 7 个历史千禧年问题的完整历史登记。

10 复现方法、来源与许可

统计步骤

1. 下载 problems.json 并保存校验值。2. 以 published=true 筛选正文。3. 检查 id 与 problem_number 的唯一性。4. 对 statement 作 NFKC 规范化并合并空白，比较文本重复。5. 在原始 title 上进行不区分大小写的词边界匹配：conjecture、conjectures、hypothesis、hypotheses。6. 按来源 category、set_id 和 status 汇总。7. 将归档记录的 duplicate_of 映射到已发布主键并生成导航。

输入文件 SHA-256

7fcc68b82cb84e39561511a839a7de9893a6c1267cef35602151a73d3bb1e6c9

检索快照为 2026-10-25；主体是下载时标为 v1.8.0 的语料，不是对 2026-10-25 以前每篇论文的实时审查。网页会变化，以上校验值用于识别本次处理的具体输入。

资料使用、来源核验与归属说明

数据归属与本报告新增内容

基础语料由 ulamai / UnsolvedMath 发布，数据卡标示 CC BY 4.0。各题原始数学内容归其作者与来源；逐条出处随记录提供。本报告新增中文评估、统计、导航、分组和排版。

原始字段与本报告的分析应当区分：记录标题、问题表述、状态、类别、归档关系来自上游；重新计数、重复文本检测、中文说明与页码导航由本报告生成。

使用某条问题开展研究前

先用编号与标题定位条目，再打开链接核对原始文献。尤其需要检查全部假设、量词、维数、底域、范畴、边界条件，以及原文是否将一个命题拆成多个分问。语料里的简写或抽取表述可能省略上下文。

查看状态时，应核查论文版本、正式发表情况、编者更新与后续纠错。一个数据库标签、一份预印本或一个 AI 证明声称，都不能单独代替对数学证明的验证。

检索日与数据日不相同

2026-10-25 是本次检索和整理日期。主体采用 v1.8.0 数据快照；不同记录的状态审查可能发生在更早的日期。网页上的最新动态没有被自动覆盖写入全部历史记录。

完整性与去重的实际含义

本报告逐条刊入所有 published=true 记录，并保留归档索引和数据附件。完整性针对这一明确的输入版本。17,614 是记录数，17,610 是简单规范化后的表述文本数，两者都不是经专家完成逻辑等价去重的猜想数。

引用本报告时建议写法

“该报告基于 UnsolvedMath v1.8.0 整理了 17,614 条已发布数学问题记录，并以 2026-10-25 的公开来源评估可见数据库规模；它不提供人类所有数学猜想的精确总数。”

引用具体数学事实时，请优先引用条目对应的原论文或问题集。本报告是导航与资料汇编，不是对全部原始数学结论的重新审定。

11 主体目录：按学科阅读

点击页码可跳转阅读。　正文共有 17,614 条，按学科分组；条目英文表述与公式源码可复制搜索。

A Bailey-Chebyshev-Bloch dictionary and terminal-choice blindness

P / partially_solved | AIM 研讨会问题汇编

Problem 2.4. Relate Bailey pair techniques with Bloch group techniques. In particular, develop a dictionary. Perhaps this might might help with the computation of torsion. Similarly, connect orthogonal polynomials to Bloch group techniques.

来源字段：https://aimath.org/WWN/mockmodular/mockmodular.pdf

00011 | AIM-ANALYTIC_NUMBER_THEORY-0028

A binary strongly stationary compatibility model for the unipotent torus

P / partially_solved | AIM 研讨会问题汇编

Can a Liouville system be isomorphic to $(\mathbb T^2,m_{\mathbb T^2},T)$, where \[T(x,y)=(x+y,y)\pmod 1? \]

The record is internally coherent. The transpose convention $T(s,t)=(s,t+s)$ occurs in Frantzikinakis--Host; exchanging the two coordinates conjugates it to the AIM convention.

There is one terminological ambiguity worth preserving. A **Liouville system** is a Furstenberg system obtained from the Liouville sequence $\lambda\in\{-1,1\}^{\mathbb Z}$ by a subsequential weak-star limit of orbit averages. The averages may be Cesàro or logarithmic, and the two resulting systems need not agree. Frantzikinakis's original unqualified formulation is Cesàro, while much of the strongest unconditional structure theory is logarithmic. The AIM record does not specify the averaging convention. The construction below is a statement about the proposed target and is relevant to either convention; comparisons with proved Liouville correlations are explicitly labeled logarithmic.

A Catalan correspondence criterion for middle Tate tensors

P / partially_solved | AIM 研讨会问题汇编

6. (J. Getz) Take a product of modular curves \(X=\prod_i X_i\). Many smaller products embed diagonally into \(X\). How much of the middle cohomology can be accounted for by these constructions?

Comments. 1) Ribet considered the product of two modular curves \(X=X_1\times X_2\); here \(NS(X)\) is just the quotient of \(\operatorname{Hom}(J(X_1),J(X_2))\) by the pullbacks of divisors on the two factors. He shows it is necessary to consider twisting correspondences, in addition to the Hecke correspondences, to complete the Tate classes. Are there similarly interesting, yet explicit, correspondences for \(X\) when we consider higher dimensional factors \(X_i\)? (J. Getz, D. Ramakrishnan, D. Ulmer)

2) For a product of four Shimura curves, there are interesting Tate classes, which are also Hodge classes, which we don't know how to represent by cycles. (D. Ramakrishnan)

A CRT lower bound for fixed-q higher divisor correlations

P / partially_solved | AIM 研讨会问题汇编

Inspection of the typeset AIM PDF confirms that the displayed expression is only \[\sum_f d_k(f)d_k(f+h), \tag{1.1} \] followed by “where \(f\) ranges over degree \(n\) polynomials” [AIM14]. There is no \(\mathcal M_n\) under the summation sign. The PDF also does not define \(d_k\), say that \(f\) is monic, or exclude \(h=0\).

The most natural recovered formulation is nevertheless the one used by the question's author immediately afterward [ABSR15]: \[S_k(n;h):=\sum_{f\in\mathcal M_n}d_k(f)d_k(f+h), \tag{1.2} \] where \(\mathcal M_n\) is the set of monic degree-\(n\) polynomials and \(d_k(f)\) counts ordered factorizations of the monic polynomial \(f\) into \(k\) monic factors, factors equal to \(1\) being allowed. One takes \(0\ne h\in\mathbb F_q[T]\) fixed. For all sufficiently large \(n\), \(\deg h<n\), so \(f+h\) is again monic of degree \(n\).

This reconstruction is labeled rather than silently imposed. Proposition 5.3 below gives the exact conversion if “degree \(n\) polynomials” literally means every leading coefficient. Proposition 5.2 treats \(h=0\), which is a genuinely different asymptotic regime.

A genus-ordering obstruction for cyclic quartic covers

P / partially_solved | AIM 研讨会问题汇编

Question 7. Does (A) fail for Z/4Z function field extensions, counted by genus?

It is Question 7 in the AIM problem-session document for the January 2014 workshop *Arithmetic statistics over finite fields and function fields*. The surrounding questions ask which ways of counting field extensions satisfy Principles (A) and (B), whether cyclic triple covers recover them when counted by genus, and whether conditioning on ramification helps.

There is a source defect that matters mathematically: neither the three-page AIM problem document nor the workshop report defines the labels (A) and (B). I therefore do **not** assign the letter (A) to a particular assertion. The strongest source-supported reconstruction comes from Melanie Matchett Wood's paper cited by the workshop report. It foregrounds exactly two properties:

- the **conditional Chebotarev property**: conditional on a place being unramified, its Frobenius/splitting distribution has the usual Chebotarev proportions; - the **local-independence property**: prescribed local behaviors at distinct fixed places are asymptotically independent.

Wood proves that both behave well for abelian number-field extensions ordered by conductor and can fail under discriminant ordering. Her non-independence result for cyclic groups of order p^2 makes local independence the especially plausible intended reading of Question 7, but the letter assignment remains unverified. This report uses neutral terminology throughout.

The main arithmetic scope below is the tame Kummer regime

\[q\equiv1\pmod4,\qquad K=\mathbb F_q(x), \]

with q fixed and geometrically connected cyclic 4-covers of $\mathbb P^1$ ordered by source genus g. The geometric theorem remains valid over an algebraically closed field of characteristic different from 2. Characteristic 2, $q\equiv3\pmod4$, constant-field extensions, and alternative weights are explicitly excluded from the arithmetic model.

A moment ladder and tuple-error barrier for a converse from bounded gaps

P / partially_solved | AIM 研讨会问题汇编

17. Elliott--Halberstam from bounded gaps.

During the workshop, much attention focused on how to prove \(\mathrm{EH}(\theta)\) with \(\theta>1/2\), so we can deduce the existence of bounded gaps between primes. V. Blomer asked whether it is possible to go the opposite way and derive an improvement on the Bombieri--Vinogradov theorem from a “strong” quantitative result on bounded gaps between primes.

R. C. Vaughan commented that such an improvement would encode so much information about \(L\)-functions that the hypothesis would have to be extremely strong.

K. Soundararajan added that the “strong quantitative result” could be as strong as the Hardy--Littlewood \(k\)-tuple conjecture with a sharp error term, say \(O(N^{1/2+\epsilon})\).

A multiplier-repetition obstruction for long prime chains

P / partially_solved | AIM 研讨会问题汇编

Let \(x\) be large and let \(p_1,\ldots,p_k\leq x\) be primes such that, for every \(j=2,\ldots,k\), \[p_j=m_jp_{j-1}+1\qquad (m_j\in\mathbb N). \] Obviously \(k=O(\log x)\). Prove or disprove that \(k=o(\log x)\).

Show that there are only finitely many \(n\) such that \(n-2^k\) is prime for every positive integer \(k\) with \(2^k<n\).

The recovered main problem is:

The same item records Montgomery's comparison with an Erdős problem:

It then says that Vaughan recalled Erdős believing that \(105\) is the largest such \(n\).

- Plain-text strings `p1`, `pk`, `pj`, `mj`, and `pj-1` were restored as \(p_1,p_k,p_j,m_j,p_{j-1}\). - In the PDF, the exponent \(k\) is set on a separate extraction line after each `2`. Thus the two corrupted strings `n - 2k` and `2 k < n` are \(n-2^k\) and \(2^k<n\), respectively. - The broken name `Erd ¨ os` was restored to Erdős. - The PDF literally says “integers \(k\),” but negative \(k\) would make \(n-2^k\) nonintegral. The standard positive-\(k\) reading is confirmed by Vaughan's 1973 formulation \(1\leq k\leq\log_2 n\) [Vaughan1973]. This is a scope clarification, not a change to the prime-chain problem.

For example, the displayed exponents make the recollection about \(105\) coherent: \(105-2^k\) for \(1\leq k\leq6\) is \(103,101,97,89,73,41\), all prime.

A ramification-bias criterion for predicted mean point counts

P / partially_solved | AIM 研讨会问题汇编

Question 20 (Melanie Matchett Wood). When do (A) and (B) predict an interesting average value of \(\#C(\mathbb F_q)\)?

Thus the verified typeset question is

The three-page problem sheet does **not** define Principles (A) and (B). The workshop report says that Wood's opening talk asked when point counts in a family can be modeled by a sum of independent identically distributed fiber variables. Questions 3--7 also connect (A), (B), automorphism weights, local behavior of field extensions, the counting invariant, and independence. Wood's contemporaneous papers make the following a natural contextual reconstruction, but it is not textually verified as the workshop's exact labeling:

- **Reconstructed (A), local marginal/mass principle:** at a rational place, a local degree-\(n\) algebra \(L\) has relative mass \(1/(|\operatorname{Aut}L|\,|D_L|)\), or the corresponding structured centralizer-weighted version when a monodromy group is fixed. - **Reconstructed (B), independence principle:** local types at distinct rational places become asymptotically independent (and are identically distributed when the geometry has no distinguished rational places).

Everything proved below is therefore a rigorous answer to this explicitly labeled reconstruction. Recovering Wood's workshop slides or notes could change which label is attached to which principle, and possibly the exact normalization. No claim below depends on calling the two principles A or B; it depends only on the stated mass and independence hypotheses.

00069 | AIM-ANALYTIC_NUMBER_THEORY-0115

A smooth-modulus 21/40 small-residue maximum and a weight-quantifier audit

P / partially_solved | AIM 研讨会问题汇编

The record is Problem 16 in the AIM workshop list *Gaps between primes* (2005). With \[\psi(x;q,a)=\sum_{\substack{n\le x\\n\equiv a\pmod q}}\Lambda(n), \] the three questions attributed to J. B. Friedlander are:

1. Show, for some fixed \(\theta>1/2\) and \(D=x^\theta\), that \[\sum_{\substack{d\le D\\(d,a)=1}}\mu(d) \left(\psi(x;d,a)-\frac{x}{\phi(d)}\right) \ll x(\log x)^{-A}. \] 2. Prove anything beyond the Bombieri--Vinogradov theorem for \[\sum_{d\le D}\max_{\substack{(a,d)=1\\|a|<(\log x)^{2005}}} \left|\psi(x;d,a)-\frac{x}{\phi(d)}\right|. \] 3. For any “reasonable” weights \(\lambda_d\), show, for some fixed \(\theta>1/2\) and \(D=x^\theta\), that \[\sum_{\substack{d\le D\\(d,a)=1}}\lambda_d \left(\psi(x;d,\bar a)-\frac{x}{\phi(d)}\right) \ll x(\log x)^{-A}, \qquad a\bar a\equiv1\pmod d. \]

The item continues with two broader prompts: obtain Bombieri--Vinogradov-type theorems for arithmetic functions other than \(\Lambda\), and formulate a reasonable zeros-of-\(L\)-functions conjecture implying \(\mathrm{EH}(\theta)\) for some \(\theta>1/2\).

The PDF displays \(A\) without a quantifier. The standard and useful reading, adopted below, is “for every fixed \(A>0\),” with constants allowed to depend on fixed parameters. This is a reconstruction, not a literal quantifier in the source.

来源字段：https://aimath.org/WWN/primegaps/WorkshopProblems.pdf

00070 | AIM-ANALYTIC_NUMBER_THEORY-0054

A split-dependent diagonal obstruction in the four-factor approximate functional equation

P / partially_solved | AIM 研讨会问题汇编

Can one prove the fourth moment formula starting from \[\int \prod_{j=1}^4\left(\sum_{n\leq x_j}\frac1{n^{1/2+it}} +\chi(s)\sum_{n\leq t/x_j}\frac1{n^{1/2-it}}\right)\,dt\ ? \]

The preceding AIM record (3.1) explicitly asks for a robust recipe based on *asymmetric approximate functional equations*. This context, the workshop report, and the standard fourth-moment notation determine the intended reading, but the display itself suppresses important information.

Put \[s=\tfrac12+it,\qquad q(t)=\frac{t}{2\pi},\qquad \chi(s)=\pi^{s-1/2}\frac{\Gamma((1-s)/2)}{\Gamma(s/2)}, \] so that \(\zeta(s)=\chi(s)\zeta(1-s)\) and \(\chi(s)\chi(1-s)=1\). The two asymmetric approximants that are actually needed are \[F_{+,x}(t)=\sum_{n\leq x}n^{-s} +\chi(s)\sum_{n\leq q(t)/x}n^{s-1}, \tag{1} \] and \[F_{-,x}(t)=\sum_{n\leq x}n^{s-1} +\chi(1-s)\sum_{n\leq q(t)/x}n^{-s}. \tag{2} \] Thus the intended object is \[\int w(t/T)F_{+,x_1}(t)F_{+,x_2}(t) F_{-,x_3}(t)F_{-,x_4}(t)\,dt, \tag{3} \] with \(w\) smooth and supported, for example, in \([1,2]\). Formula (3) models \(\zeta(s)^2\zeta(1-s)^2=|\zeta(s)|^4\). Taken literally, the AIM display has four copies of (1) and therefore models \(\zeta(s)^4\), not the fourth absolute moment. Moreover, under the displayed standard definition of \(\chi\), complementary cutoffs satisfy \(xy=q(t)=t/(2\pi)\), not \(xy=t\). The missing \(2\pi\) can only be harmlessly suppressed if it has been absorbed into the convention for the \(x_j\). Hard cutoffs also create moving boundary terms; a proof should first smooth them or track them explicitly.

The recovered target, at minimum, is Ingham's leading formula \[\int_0^T|\zeta(\tfrac12+it)|^4\,dt \sim \frac{1}{2\pi^2}T(\log T)^4. \tag{4} \] The stronger established target is \(T P_4(\log T)+E_2(T)\), where \(P_4\) is an explicit polynomial of degree four with leading coefficient \(1/(2\pi^2)\).

00073 | AIM-ANALYTIC_NUMBER_THEORY-0008

A weighted large-sieve reduction and an exponent obstruction

P / partially_solved | AIM 研讨会问题汇编

It asks for a bound

$$ \sum_{f,g\in \mathcal B_k} L(1/2,\operatorname{sym}^2 f)L(1/2,\operatorname{sym}^2 g) \left|\sum_{n\leq k}\lambda_f(n)\lambda_g(n+h)\right|^2 \ll k^{4-\delta} \tag{1.1} $$

for $|h|\ll1$ and some $\delta>0$, by a delta method. It says that (1.1), conditionally on nonnegativity of the central values, would imply the holomorphic QUE result of Holowinsky and Soundararajan.

The record does not define $\mathcal B_k$, the normalization of $\lambda_f(n)$, or whether the outer sum is harmonic. The standard reconstruction used here is:

* k is a large even integer; * $\mathcal B_k=H_k$ is the Hecke-normalized orthogonal basis of level-one, weight-k cusp forms, with $f(z)=\sum_{n\geq1}\lambda_f(n)n^{(k-1)/2}e(nz)$ and $\lambda_f(1)=1$; * hence $|H_k|=k/12+O(1)$, and Deligne gives $|\lambda_f(n)|\leq d(n)$; * the outer sum in (1.1) is a natural, not a Petersson-harmonic, family sum.

This is an explicit reconstruction, not text verified on the unavailable AIM page. If $\mathcal B_k$ instead means an orthonormal Fourier basis, or if harmonic weights are intended, both the scale and the applicable trace formula change.

There is a second ambiguity: $|h|\ll1$ includes $h=0$, whereas the QUE shifted-convolution criterion has a Rankin--Selberg main term at zero shift. Cancellation should be requested for fixed $h\ne0$; $h=0$ must be separated and its main term retained. The algebra below remains valid whenever all $n+h$ are positive.

Additive gaps and an affine-coordinate audit

P / partially_solved | AIM 研讨会问题汇编

Question 13 (Pollack). What can we say (resp. what do we know) about gaps between irreducible polynomials over Fq?

The typeset question ends after \(\mathbb F_q\).

There are several inequivalent notions that the word “gap” could denote in \(\mathbb F_q[T]\). The intended one can nevertheless be recovered with high confidence. Question 12 immediately before this record concerns additive shifts \(f\) and \(f+h\). More decisively, the paper of Castillo, Hall, Lemke Oliver, Pollack, and Thompson states that its work began at this same AIM workshop and develops “bounded gaps” over \(\mathbb F_q(t)\). In its fixed-degree application, a gap is the polynomial difference between two monic irreducibles of the same degree.

Accordingly, let \(\mathcal P_{q,n}\) be the set of monic irreducible polynomials of degree \(n\) in \(A=\mathbb F_q[T]\).

1. For which nonzero \(h\in A\) are there infinitely many \(n\) and \(P,Q\in\mathcal P_{q,n}\) with \(P-Q=h\)? 2. For a fixed \(h\), what is the asymptotic count of such pairs as \(n\to\infty\) with \(q\) fixed? 3. Can one at least prove the existence of pairs for which \(\deg(P-Q)\), equivalently \(|P-Q|=q^{\deg(P-Q)}\), stays bounded as \(n\to\infty\)? 4. How large is the gap set \[\mathcal D_{q,n}=\{P-Q:P,Q\in\mathcal P_{q,n},\ P\ne Q\}\subseteq\{h:\deg h<n\}? \]

This is also the short-interval interpretation: \(\deg(P-Q)\le d\) precisely when \(P\) and \(Q\) lie in the same radius-\(q^d\) ball for the norm at the chosen place at infinity.

Two other readings are rejected. A “degree gap” between available irreducible degrees is trivial, since irreducibles exist in every positive degree.

P / partially_solved | AIM 研讨会问题汇编

This is Problem 15 in the AIM workshop list *Gaps between primes*. The official PDF is the authority for the reconstruction below.

Let $$ P_{\mathcal H}(n)=\prod_{i=1}^k(n+h_i),\qquad \log^+x=\max(0,\log x). $$ The PDF defines the truncated divisor sum $$ \Lambda_R(n;\mathcal H)=\sum_{d\mid P_{\mathcal H}(n)}\lambda_d, \qquad \lambda_d=\mu(d)\frac{\bigl(\log^+(R/d)\bigr)^{k+\ell}}{(k+\ell)!}. \tag{1.1} $$ Conrey asked whether a quantitatively stronger method results from other divisor coefficients. One proposed family was $$ \lambda_d=\mu(d) \left\{\prod_{p\mid d}f\!\left(\frac{\log p}{\log R}\right)\right\} Q\!\left(\log^+(R/d)\right), \tag{1.2} $$ with smooth functions f,Q. Vaughan suggested testing other traditional sieve weights. A third suggestion was to combine upper and lower sieves in the style of Chen; Soundararajan warned that the negative contribution would have to be calculated.

There is a crucial notational distinction. The object in (1.1) is a possibly signed **divisor sum**. In the GPY positivity argument, the actual test weight is $$ w(n)=\Lambda_R(n;\mathcal H)^2\geq 0. \tag{1.3} $$ More generally, one can square a linear combination of divisor sums. Negative divisor coefficients or negative cross terms inside this square do not make w signed. A genuinely signed upper-minus-lower weight is a different object and loses the automatic positivity inference unless its negative contribution is controlled.

00102 | AIM-ALGEBRAIC_NUMBER_THEORY-0019

An exact nonrational double-cover source for dense quadratic points

P / partially_solved | AIM 研讨会问题汇编

The following is asked in analogy with a result of Harris and Silverman showing that, for a curve C/k, $2\in\delta(C/k)\iff C$ is a double cover of $\mathbb P^1$ or a positive rank elliptic curve (see https://www.ams.org/journals/proc/1991-112-02/S0002-9939-1991-1055774-0/S0002-9939-1991-1055774-0.pdf).

Classify surfaces X/k of general type with $2\in\delta(X/k)$, possibly using geometric and/or dynamical constructions.

Vojta has prove that for a hyperelliptic curve C/k of genus ≥4, all but finitely many degree 2 points are contracted by its hyperelliptic map.

If $\operatorname{irr}(X)=2$, there exists a dominant map $X\dashrightarrow\mathbb P^2$ of degree 2. What conditions on X guarantee that the set of quadratic points on X not arising from this map is not Zariski dense?

An explicit CM projector and Kummer correspondence

P / partially_solved | AIM 研讨会问题汇编

Let \(E\) be an elliptic curve over \(\mathbb Q\) with CM by \(K\) and with associated Hecke character \(\chi\). Then \(\chi^2\) is associated to a modular form of weight 3 appearing in \(H^2(\mathcal E)\), \(\mathcal E\to X\) for a modular curve \(X\) (whose level is the norm of the conductor of \(\chi^2\) times the discriminant of \(K\)). The Tate and Hodge Conjectures predict the existence of a correspondence \(E\times E\to\mathcal E\) because the same motive appears in \(H^2\) of both sides. Can we exhibit this correspondence explicitly?

00106 | AIM-ALGEBRAIC_NUMBER_THEORY-0105

An explicit cubic point and its descent certificate

S / solved | AIM 研讨会问题汇编

Put \[g(T)=3(T^4-54T^2-117T-243),\qquad p(X)=X^2+1,\qquad q(X)=X^2+2. \] The official AIM workshop PDF, *Rational and integral points on higher dimensional varieties*, Question 20, asks whether the surface with affine open \[S_{\mathrm{AIM}}:\qquad y^2=g(t)p(x),\qquad z^2=g(t)q(x) \tag{1} \] has a point over some odd-degree number field. The question attributes to Skorobogatov the facts that a smooth projective model \(S/\mathbb Q\) has \(S(\mathbb Q)=\varnothing\) and \(S(\mathbb A_{\mathbb Q})^{\mathrm{Br}}\ne\varnothing\).

There is an important coordinate convention. Skorobogatov's example and the opening display in Creutz's paper use \[S_0:\qquad p(x)\widetilde y^2=q(x)\widetilde z^2=g(t). \tag{2} \] On the common open where \(p(x)q(x)\ne0\), the two presentations are related by \[y=p(x)\widetilde y,\qquad z=q(x)\widetilde z, \tag{3} \] with inverse \(\widetilde y=y/p(x)\), \(\widetilde z=z/q(x)\). Creutz explicitly describes (1) as a change of variables from (2). All point coordinates below are labeled by convention. Since the point obtained lies in this common affine open, it gives a point on the intended smooth projective surface under either presentation.

Arithmetic surjectivity forces recurrence of locally soluble fibers

P / partially_solved | AIM 研讨会问题汇编

Problem 4. Viray: Let \(\phi:X\to E\) be a fibration over an elliptic curve of positive rank over \(\mathbb Q\) whose generic fiber is smooth and geometrically irreducible. Let \[Z=\{p\in E(\mathbb Q)\mid X_p=\phi^{-1}(p)\text{ has points everywhere locally}\}. \] What can we say about \(Z\)? Is \(|Z|<\infty\) with \(Z\ne\varnothing\) possible?

The motivation is that work of Poonen, Skorobogatov-Harpaz and Colliot-Thélène-Pál-Skorobogatov constructs \(X\) failing the Hasse principle such that none of the known obstructions apply. All of these use a map \(X\to C\) to a curve with \(0<|C(\mathbb Q)|<\infty\).

Browning: The case where \(\phi\) is a conic bundle may already be interesting.

Bounded-degree decisions and local-density support for rational curves on quartic K3 surfaces

P / partially_solved | AIM 研讨会问题汇编

Let \(U\) be the complement of all rational curves over \(\mathbf Q\).

The relevant opening assertion is:

For a smooth quartic surface \(X\subset \mathbf P^3_{\mathbf Q}\), assuming \(U(\mathbf Q)\ne\varnothing\), the source reports numerical evidence for \[N_U(B):=\#\{u\in U(\mathbf Q):H(u)\le B\} \sim c(\log B)^{\rho(X)}, \tag{1} \] where \(\rho(X)\) is the rank of the Picard group and \(c\) is described as a product of local densities. It then asks the following related questions.

1. Can (1) hold when weak approximation fails? 2. Given a quartic K3 surface \(X/\mathbf Q\) and \(x\in X(\mathbf Q)\), is there a procedure deciding whether \(x\) lies on a rational curve over \(\mathbf Q\)? 3. What changes if elliptic curves are also removed? 4. What numerical evidence exists, and what is the “Peyre freedom” of low-degree rational curves? 5. If \(X/\mathbf Q\) is a K3 surface with a rational point, must it contain a rational curve defined over \(\mathbf Q\)? Must one pass through a prescribed \(x\in X(\mathbf Q)\)? 6. For \(X/\mathbf F_q\) and \(x\in X(\mathbf F_q)\), is there an \(\mathbf F_q\)-defined rational curve through \(x\)? Does \(X\) contain any \(\mathbf F_q\)-defined rational curve? 7. The source notes a Bogomolov--Tschinkel result for Kummer surfaces. 8. Can a K3 surface \(X/\mathbf Q\) with \(\operatorname{Pic}(X_{\mathbf C})\simeq\mathbf Z\) have infinitely many rational curves defined over \(\mathbf Q\)?

These ranks must not be silently identified.

The source does not normalize \(H\). For definiteness, this report uses the standard multiplicative height induced by \(\mathcal O_X(1)\), obtained from primitive integral projective coordinates by \(H([x_0:\cdots:x_3])=\max_i|x_i|\). Changing the adelic metric changes the constant \(c\), not the logical conclusions below. The complement \(U\) is a set-theoretic complement of a countable union and need not be Zariski open.

Character-phase evidence for Elliott--Halberstam and a sparse twisted-psi diagonal

P / partially_solved | AIM 研讨会问题汇编

What evidence exists in support of the Elliott--Halberstam conjecture (EH)? Vaughan suggested that progress would most likely exploit cancellation among the values of \(\overline\chi(a)\) in \[\psi(x;q,a)=\frac{1}{\phi(q)}\sum_{\chi\bmod q}\overline\chi(a)\psi(x,\chi). \] Conrey asked whether known asymptotics for \[\sum_{\chi\bmod q}^{*}\chi(a)|L(1/2,\chi)|^2 \] suggest that the desired cancellation is nonexistent. Soundararajan replied that the latter behavior comes from the Euler product and has no analogue for \(\psi(x,\chi)\).

With only those typographical defects repaired, the key passage is:

Here \(^*\) means primitive characters. These corrections are confirmed by page 1 of the PDF.

For a precise modern target, put \[\Delta(x;q,a)=\psi(x;q,a)-\frac{x}{\phi(q)},\qquad \psi(x;q,a)=\sum_{\substack{n\le x\\n\equiv a\pmod q}}\Lambda(n). \] The standard Elliott--Halberstam assertion is that, for every \(A>0\) and every fixed \(\theta<1\), \[\sum_{q\le x^\theta}\max_{(a,q)=1}|\Delta(x;q,a)| \ll_{A,\theta}\frac{x}{(\log x)^A}. \tag{EH} \] Thus the record contains three connected questions: what theorem-level evidence supports (EH), what character-phase cancellation would explain it, and whether a twisted second moment of central \(L\)-values obstructs that mechanism.

Common twists, sparse families, and the marked-torsor bottleneck

P / partially_solved | AIM 研讨会问题汇编

Does Bhargava's machinery have implications for the Hasse principle for special surfaces? For example, let $F,G\in\mathbb Q[x,y]$ be homogeneous polynomials of degree 3. Consider the cubic surface \[S=\{F(x,y)=G(z,w)\}\subset\mathbb P^3_{\mathbb Q}. \] The defining equation is equivalent to the system of equations \[u^3=tF(x,y),\qquad v^3=tG(z,w). \] This defines a family of cubic twists of curves of genus 1 over the t-line. Swinnerton-Dyer has discussed how to search for t such that this system is solvable over $\mathbb Q$ in the diagonal case [Ann. Sci. ENS]. Can we extend his work beyond the diagonal case? Similarly, consider Kummer K3 surfaces defined by \[z^2=f(x)g(y), \] where f,g are quartic separable polynomials. This is equivalent to the family of quadratic twists of curves of genus 1 defined by \[u^2=tf(x),\qquad v^2=tg(y). \] The goal is to eliminate the condition in Swinnerton-Dyer's work that (the 2-primary part of) $\Sha$ has finite order for quadratic twists, using the recent work presented in Bhargava's talk.

The best improvement to this lower bound I am aware of is by Morrill, Platt, and Trudgian [MPT] (improving work of Kaczorowski [K2]), who proved that \[\liminf \frac{W^\psi(T)}{\log T} \ge \frac{\gamma_1}{\pi} + 1.867\cdot10^{-30}. \]

Improve this lower bound, even assuming RH. Here are some suggested target lower bounds for $\liminf {W^\psi(T)}/{\log T}$: (a) $1.01 \frac{\gamma_1}\pi$; (b) $2 \frac{\gamma_1}\pi$; (c) ∞.

What we expect to be true is that the large-scale intervals of positive and negative values of $\psi(x)-x$ do indeed alternate at about the speed given by the repeated-averaging argument, but that each such sign change detected is actually a flurry of many sign changes on a small scale (this is how random walks behave, for example). In particular, we expect $W^\psi(T)$ and related sign-change counting functions to grow more like $\sqrt T$ (up to logarithmic factors) than like $\log T$.

Comparative Prime Number Theory - Problem 10

O / open | AMR 问题清单汇编

- (Stanley Yao Xiao, University of Northern British Columbia) Let $f \in \mathbb{Z}[x,y]$ be a primitive, positive definite binary quadratic form such that $f(x,1) \not\equiv x(x+1) \pmod{2}$. Consider the counting function for the generalized Friedlander--Iwaniec primes \[\pi_f(x) = \# \{p \leq x \colon p = f(a,b^2) \text{ for some integers a and b}\}. \] By the main theorem in my paper [X], we have $\pi_f(x) \sim C(\operatorname{Disc}(f)) x^{3/4}/\log x$ for some positive constant $C(\operatorname{Disc}(f))$ depending only on the discriminant of f.

If f and g are two distinct such quadratic forms with the same discriminant, how do the quantities $\pi_f(x)$ and $\pi_g(x)$ compare as $x \rightarrow \infty$?

A similar question can be asked for indefinite binary quadratic forms, where the analogous counting function must restrict a and b to a suitable ``box'' depending on x.

Heath-Brown and Moroz [HBM] gave a similar asymptotic formula for primitive binary cubic forms F such that $F(x,y) \not\equiv xy(x+y) \pmod{2}$; one could again look for pairs F,G of distinct such cubic forms such that $\pi_F(x) \sim \pi_G(x)$ and compare those counting functions to each other.

- (Shin-ya Koyama, Toyo University) A new formulation of Chebyshev's bias was given in [AK] in terms of the difference of the weighted counting function of prime numbers p as \begin{equation*} \sum_{\genfrac{}{}{0pt}{1}{p\le x}{p\equiv 3\mod4}} \frac 1{\sqrt p} -\sum_{\genfrac{}{}{0pt}{1}{p\le x}{p\equiv 1\mod4}} \frac 1{\sqrt p} \sim\frac12\log\log x\quad(x\to\infty). \end{equation*} **Problem**: What is the logical inclusion or relation of this new definition to the conventional definiton of ``Chebyshev's bias'' in terms of the logarithmic density of the set of x satisfying $\pi(x,4,3)>\pi(x,4,1)$ being very close to 1?

- (Greg Martin, University of British Columbia) This question was asked by Carl Pomerance and appears in [Mar, Section 3]. Let a and b be distinct reduced residue classes modulo q.

背景链接：https://arxiv.org/abs/2407.03530

00233 | AMR-116-0010

Comparative Prime Number Theory - Problem 11

O / open | AMR 问题清单汇编

- (Greg Martin, University of British Columbia) This question was asked by Carl Pomerance and appears in [Mar, Section 3]. Let a and b be distinct reduced residue classes modulo q.

Prove unconditionally that the set of x for which $\pi(x;q,a)=\pi(x;q,b)$ (the set of ``ties'' in the prime number race) has (natural or logarithmic) density 0.

If we assume GRH and a very mild version of LI (see [Devin, Theorem 2.2]), the limiting logarithmic distribution of $\bigl(\pi(x;q,a)=\pi(x;q,b) \bigr) (\log x)/\sqrt x$ exists and is absolutely continuous with respect to Lebesgue measure. Consequently, for any function $f(x)$ that is $o(\sqrt x/\log x)$, the set of x for which $\bigl| \pi(x;q,a)=\pi(x;q,b) \bigr| < f(x)$ has logarithmic density 0; this conclusion is far stronger than ``ties have density $0$''. But ``ties have density 0'' is such a weak assertion that we might hope to prove it unconditionally.

00234 | AMR-116-0011

Comparative Prime Number Theory - Problem 12

O / open | AMR 问题清单汇编

- (Daniel R. Johnston, University of New South Wales--Canberra at ADFA) Define \[S(x)=\sum_{n\leq x}(-2)^{\Omega(n)} \qquad\text{and}\qquad \alpha = \limsup_{x\to\infty}\frac{|S(x)|}{x}. \] In a soon-to-be-released preprint by students at UNSW--Canberra, it is shown that α exists, and a (large) upper bound is given. Note that $S(x)$ has jump discontinuities of size x when x is a power of 2, which implies the lower bound $\alpha\ge\tfrac{1}{2}$. A conjecture [sun2016pair, Conjecture 1.1], supported by extensive computations [mossinghoff2021oscillations], asks whether $\alpha\leq 1$.

What is the exact value of α?

- (Greg Martin, University of British Columbia) The standard way to investigate the frequency of sign changes of error terms such as $\psi(x)-x$ is to use repeated averaging so that the largest term in the explicit formula eventually dominates the sum of all other terms. In this way, one shows that the number of sign changes is essentially at least as large as the number of sign changes of that largest term. For example, Kaczorowski [K1] showed unconditionally that \[\liminf \frac{W^\psi(T)}{\log T} \ge \frac{\gamma_1}{\pi}. \] This result can be generalized to many other error terms (although more generally one must assme that the relevant L-functions have no real zeros, and GRH tends to be necessary for error terms with biases).

The best improvement to this lower bound I am aware of is by Morrill, Platt, and Trudgian [MPT] (improving work of Kaczorowski [K2]), who proved that \[\liminf \frac{W^\psi(T)}{\log T} \ge \frac{\gamma_1}{\pi} + 1.867\cdot10^{-30}. \]

Comparative Prime Number Theory - Problem 18

O / open | AMR 问题清单汇编

It could be more challenging to bound the densities in three-way races sufficiently well to verify that such a list is exhaustive: as Lamzouri [Lam] showed, the rate of convergence of three-way race densities to $\frac16$ is only $O(1/\log q)$, as opposed to a $q^{-1/2+o(1)}$ rate of convergence to $\frac12$ for densities in the two-way case.

- (Greg Martin, University of British Columbia)

Compute (assuming GRH and LI) the densities in the five-way race among the quadratic residues and among the quadratic nonresidues modulo 11.

There are 120 densities of the form $\delta_{11;a_1,a_2,a_3,a_4,a_5}$ where $\{a_1,a_2,a_3,a_4,a_5\} = \{1,3,4,5,9\}$ (the quadratic residues modulo 11). There is a known formula [FeM, Theorem 4] for $\delta_{q;a_1,a_2,a_3,a_4,a_5}$ that can in principle be computed to any desired accuracy; however, the formula involves a four-dimensional integral that was beyond the authors' computational ability at the time.

In addition to being the simplest natural five-way prime number race, Bays and Hudson [BH] noticed that this particular race exhibited an interesting cyclic phenonemon, which the computation of these densities might shed some light on.

Because of the symmetries in [FeM, Theorem 2], there are only 8 (presumably) distinct values among these 120 densities, so all that would need to be computed are $\delta_{11;1, 3, 4, 5, 9}$, $\delta_{11;1, 3, 4, 9, 5}$, $\delta_{11;1, 3, 5, 4, 9}$, $\delta_{11;1, 3, 5, 9, 4}$, $\delta_{11;1, 3, 9, 5, 4}$, $\delta_{11;1, 5, 3, 4, 9}$, $\delta_{11;1, 5, 3, 9, 4}$, and $\delta_{11;1, 5, 9, 3, 4}$. By the same theorem, these values also represent all possible densities in the five-way race among the quadratic nonresidues $\{2,6,7,8,10\}$ modulo 11.

- (Nathan Ng, University of Lethbridge) My Ph.D. thesis [NgPhd] contains some computations of numerical examples of prime number races in Chebotarev's density theorem. There is now a large database of zeros of Artin L-functions at the LMFDB [LMFDB], as well as Rubinstein's lcalc program which has been integrated into SageMath.

00240 | AMR-116-0019

Comparative Prime Number Theory - Problem 20

O / open | AMR 问题清单汇编

- (Greg Martin, University of British Columbia) In 1959 Shanks [Shanks] made an observation that seems to have been overlooked since then: some combinatorial reasoning led him to assert that for each integer $k\ge1$, the odd numbers n with $\Omega(n)=k$ should be biased towards the residue class $(-1)^k\mod4$, where the case $k=1$ is Chebyshev's original observation. In other words, $(-1)^{\Omega(n)}\chi_{-4}(n)$ should be biased towards 1 over -1.

Assuming GRH and LI, calculate the logarithmic density of the sets \[\{n\ge1\colon (-1)^{\Omega(n)}\chi_{-4}(n) = 1\} \quad\text{and}\quad \{n\ge1\colon (-1)^{\Omega(n)}\chi_{-4}(n) = -1\}. \] Presumably a similar phenomenon should hold for $(-1)^{\Omega(n)}\chi(n)$ for any quadratic character χ; the case $\chi=\chi_{-3}$ (the nonprincipal Dirichlet character modulo 3) might be particularly pronounced.

By the way, [Shanks] also contains the timeless quip ``Since $\log\log\log n\to\infty$ (with great dignity)\dots.''

- (Daniel R. Johnston, University of New South Wales--Canberra at ADFA). It has been shown [johnston2023average, Theorem 1.1] that RH is equivalent to \[{\mathfrak{A}}_1^\pi(x) = \int_0^x \bigl(\pi(t)-\mathop\mathrm{li}(t) \bigr) dt < 0 \quad\text{for all $x>2$.} \] Roughly, the reason this inequality holds under RH is that the constant $\sum_{\rho} 1/\rho(\rho+1)$ occuring in the explicit formula for ${\mathfrak{A}}_1^\pi(x)$ is too small to overcome the bias. However, Martin pointed out (private communication) that when looking at the analogous \[{\mathfrak{A}}_1^\pi(x;q,a) = \int_0^x \bigl(\phi(q)\pi(t;q,a)-\mathop\mathrm{li}(t) \bigr) dt, \] the corresponding sum over zeros of Dirichlet L-functions grows faster than the bias as q increases, and thus at some point the inequality ${\mathfrak{A}}_1^\pi(x;q,a) < 0$ should fail when q is large.

One needs to be careful with higher-degree L-functions since there are known barriers to LI, such as: the factorization of Dedekind ζ-functions and Artin L-functions into other L-functions; the vanishing of elliptic curve L-functions at the central point; and the ability to shift an entire L-function vertically if we don't restrict to the central character.

- (Alexandre Bailleul, Université Paris--Saclay) As a concrete instance of the above problem:

Can we obtain upper bounds for $1/{|\zeta'(\rho)|}$ as ρ runs over the nontrivial zeros of $\zeta(s)$?

Assuming SZ for $\zeta(s)$, the Mertens sum has the explicit formula \begin{equation*} M_0(x) = \sum_\rho \frac{x^\rho}{\rho \zeta'(\rho)} -2 + \sum_{n= 1}^\infty \frac{(-1)^{n-1}(2\pi)^{2n}}{(2n)!n\zeta(2n+1)x^{2n}}. \end{equation*} The order of the quantity $1/|\zeta'(\rho)|$ is a huge open problem that is difficult to approach. We have an exact formula (see [Tao]) \begin{equation}

\frac{1}{\zeta'(\rho)} = \lim_{s\to \rho}\frac{s-\rho}{\zeta(s)}= -\frac{2e^{1-B\rho}\rho(\rho-1)\Gamma(1+\rho/2)\pi^{-\rho/2}}{\prod_{\rho'\neq \rho}(1-\tfrac{\rho}{\rho'})e^{\rho/\rho'}}, \end{equation} where $B= -0.0230957\ldots$ is the constant appearing in the Weierstrass product for $\xi(s)$. Thus the main issue here is bounding the term $1- \tfrac{\rho}{\rho'}$, in other words, obtaining a lower bound for the distance $|\rho -\rho'|$ from a zero to its nearest neighbour. Even assuming SZ, we cannot yet rule out the existence of two extremely close zeros.

- (Nathan Ng, University of Lethbridge) My Ph.D. thesis [NgPhd] contains the conjecture \[\sum_{0 < \gamma < T} \biggl| \frac{\zeta(2 \rho)}{\zeta'(\rho)} \biggr|^2 \sim \frac{1}{2 \pi} T. \] **Problem 1**: Use the argument in Milinovich and Ng [MN] to establish the lower bound \[\sum_{0 < \gamma < T} \biggl| \frac{\zeta(2 \rho)}{\zeta'(\rho)} \biggr|^2 \ge \biggl(\frac{1}{4 \pi} + o(1) \biggr) T. \] **Problem 2**: Prove lower bounds for the discrete moments of the shape \[\sum_{0 < \gamma < T} \biggl| \frac{\zeta(2 \rho)}{\zeta'(\rho)} \biggr|^{2k} \gg T (\log T)^{(k+1)^2}. \] See the articles of Heap, Li, and Zhao [HLZ] and Gao and Zhao [GZ], where the authors prove lower bounds of the type \[\sum_{0 < \gamma < T} \frac{ 1}{|\zeta'(\rho)|^{2k}} \gg T (\log T)^{(k+1)^2} \] for $k >0$.

- (Nicol Leong, University of New South Wales--Canberra at ADFA)

Can we improve upper bounds for the multiplicities of nontrivial zeros of $\zeta(s)$?

Let $m(\rho)$ denote the multiplicity of a nontrivial zero of $\zeta(s)$. We know unconditionally that \begin{equation*} m(\beta +i\gamma) \ll \log \gamma, \end{equation*} while under the assumption of the Lindel\"of hypothesis or the Riemann hypothesis, the bound can be improved to \begin{equation*} o(\log \gamma) \qquad \text{or} \qquad \ll\frac{\log \gamma}{\log\log \gamma}, \end{equation*} respectively. Ivi\'c has proved a couple of unconditional results of order $\ll \log\gamma$, but this is still far from Karatsuba's conjectured size of $\ll 1$. (Of course, under the LI conjecture, $m(\rho)$ would equal 1 for all ρ.) For more details on the problem and Ivi\'c's approach, see for instance [Ivic1,Ivic2].

- (Alexandre Bailleul, Université Paris--Saclay) Skewes's number is defined as the smallest x such that $\pi(x) > \mathop\mathrm{li}(x)$. It was shown to exist by Littlewood, and a first (enormous) bound was found by Skewes. Its value is still unknown, but it must be quite large since it is known to lie in the interval $(10^{19}, 1.3971653 \times 10^{316})$ (the lower bound is due to Büthe [Buthe0], while the upper bound is due to Saouter, Trudgian, and Demichel [STD]); experts suggest that it is quite close to this upper bound. The corresponding logarithmic density for the race between $\pi(x)$ and $\mathop\mathrm{li}(x)$ was determined to be extremely small by Rubinstein and Sarnak [RS], namely $\delta(\pi,\mathop\mathrm{li}) \approx 2.6 \times 10^{-7}$.

Another example of a race with a large bias is the race between primes congruent to $2\mod3$ versus primes congruent to $1\mod3$. Rubinstein and Sarnak [RS] calculated the corresponding logarithmic density $\delta_{q;1,2} \approx 1.0\times10^{-3}$, while Bays and Hudson shows that the first sign change of $\pi(x;3,2) - \pi(x;3,1)$ occurs at $x=608{,}981{,}813{,}029$. Therefore, it seems natural to think that the size of the ``Skewes's number'' of a prime number race is correlated with how biased that race is. In particular, classical prime number races have their logarithmic densities tending to $\frac12$ as $q \to \infty$, and so we might expect the corresponding Skewes's numbers to be less and less extreme (but of course bounded below by the modulus q).

背景链接：https://arxiv.org/abs/2407.03530

Comparative Prime Number Theory - Problem 6

O / open | AMR 问题清单汇编

Another example of a race with a large bias is the race between primes congruent to $2\mod3$ versus primes congruent to $1\mod3$. Rubinstein and Sarnak [RS] calculated the corresponding logarithmic density $\delta_{q;1,2} \approx 1.0\times10^{-3}$, while Bays and Hudson shows that the first sign change of $\pi(x;3,2) - \pi(x;3,1)$ occurs at $x=608{,}981{,}813{,}029$. Therefore, it seems natural to think that the size of the ``Skewes's number'' of a prime number race is correlated with how biased that race is. In particular, classical prime number races have their logarithmic densities tending to $\frac12$ as $q \to \infty$, and so we might expect the corresponding Skewes's numbers to be less and less extreme (but of course bounded below by the modulus q).

Obtain an upper bound for the first sign change of $\pi(x;q,a)-\pi(x;q,b)$ in terms of q, preferably one that increases as slowly as possible.

- (Daniel R. Johnston, University of New South Wales--Canberra at ADFA) This question was posed during Ethan Lee's talk at the CPNTS.

Given a number field $\mathbb{K}$ with ring of integers $\mathcal{O}_{\mathbb{K}}$, let $\kappa_{\mathbb{K}}$ be the residue at the pole $s=1$ for the Dedekind zeta-function $\zeta_{\mathbb{K}}(s)$ associated to $\mathbb{K}$. Consider the difference \[\Delta_{\mathbb{K}}(x)=\prod_{N(\mathfrak{p})\leq x}\left(1-\frac{1}{N(\mathfrak{p})}\right)^{-1}-e^{\gamma}\kappa_{\mathbb{K}}\log x, \] where the product runs over the prime ideals $\mathfrak{p}$ of $\mathcal{O}_{\mathbb{K}}$ with norm $N(\mathfrak{p})$ up to x; this difference $\Delta_K(x)$, which tends to be positive, is connected to Mertens's third theorem for number fields. B\"uthe [buthe2015first] showed that the first negative value of $\Delta_{\mathbb{Q}}(x)$ occurs before $2\cdot 10^{215}$. On the other hand, as shown in [hathi2021mertens, Table 1], the tendency for $\Delta_{\mathbb{K}}(x)$ to be positive is weaker (in terms of logarithmic density) for the simple number fields $\mathbb{K}=\mathbb{Q}(\sqrt{5})$ and $\mathbb{K}=\mathbb{Q}(\sqrt{13})$ than for $\mathbb{K}=\mathbb{Q}$. It's unclear whether this should mean that the first negative values of $\Delta_{\mathbb{K}}(x)$ in these cases should occur sooner than those of $\Delta_{\mathbb{Q}}(x)$.

Localize the first negative value for $\Delta_{\mathbb{K}}(x)$ when $\mathbb{K}$ is $\mathbb{Q}(\sqrt{5})$, $\mathbb{Q}(\sqrt{13})$, or some other simple number field. In general, obtain an upper bound for the first sign change of $\Delta_{\mathbb{K}}(x)$ for a family of number fields $\mathbb{K}$.

- (Alexandre Bailleul, Université Paris--Saclay) There exist highly biased races, such as the (appropriately normalized) race between quadratic residues and nonresidues for composite moduli q. Fiorilli [Fio] formulated a conjecture for the Skewes's number of this race between residues and nonresidues (the smallest real number for which the counting function for primes that are quadratic residues overcomes the bias): it is roughly of the form $\exp\bigl(\exp\bigl({\rho(q)}/\log{\mathrm{rad}(q)} \bigr) \bigr)$, where $\rho(q)$ is the index of the subgroup of squares in $(\mathbb{Z}/q\mathbb{Z})^{\times}$ and $\mathrm{rad}(q)$ is the radical (largest squarefree divisor) of q.

More recently, Fiorilli and Jouve [FJ] and Bailleul [Bai] have investigated similar highly-biased races in number fields.

Bound Skewes's numbers of other highly biased races in terms of the parameters defining the race, either conjecturally or provably.

- (Alexandre Bailleul, Université Paris--Saclay) Consider Chebyshev's bias in the function field setting. As is customary since the work of Cha [Cha], in addition to assuming the linear independence (over ${\mathbb{Q}}$) of the corresponding arguments of zeros of L-functions, one typically assumes that those arguments are linearly independent with π as well. While there are no known rational linear relations among the arguments of these zeros themselves, there are known instances where such an argument is a rational multiple of π. These instances usually come from special geometric conditions, such as supersingularity of elliptic curves or jacobians that are not absolutely simple.

Coupled rank-two Nahm sums as modular units and partition series

P / partially_solved | AIM 研讨会问题汇编

Problem 2.3. Look at explicit examples where r ≥ 2 and fA,B,C (τ) is modular. Can we write these in terms of natural objects? Similarly, can we related them to combinatorial identities; in the case r = 1, the two triples given relate to the Rogers-Ramanujan identities.

The record reads, exactly:

The preceding paragraph of the original PDF supplies the notation. In standard typesetting, it is \[f_{A,B,C}(\tau) :=\sum_{n_1,\ldots,n_r\geq 0} \frac{q^{\frac12\mathbf n^{T}A\mathbf n+B^{T}\mathbf n+C}} {(q;q)_{n_1}\cdots(q;q)_{n_r}}, \qquad q=e^{2\pi i\tau}, \] where \(A\in M_{r\times r}(\mathbb Q)\) is symmetric positive definite, \(B\in\mathbb Q^r\), \(C\in\mathbb Q\), and \[(q;q)_m=\prod_{k=1}^{m}(1-q^k),\qquad (q;q)_0=1. \] The PDF prints the quadratic term using vector arrows and a transpose; comparison with the clean definition in the later literature confirms the displayed reconstruction.

There are two separate source issues:

The task is an open-ended request for examples and interpretations, rather than a single proposition. This report gives a proved, genuinely coupled rank-two pair, identifies it simultaneously as a product of modular units and as a partition generating function, and supplies an explicit partition bijection for the key rank-two-to-rank-one collapse.

Cubic points in the plane and the two exceptional sets

P / partially_solved | AIM 研讨会问题汇编

It asks for a Manin-type conjecture for degree-\(d\) points on a Fano variety \(X/k\). Its displayed counting function is \[N_{X,\mathscr L}(U,B;d) = \#\{x\in U(\overline k):h_{\mathscr L}(x)\leq B,\ [\kappa(x):k]=d\}, \] and the proposed form is \(cB^a(\log B)^b\). It asks for \(a,b,c\), for the correct shape of \(U\), and particularly for \(X=\mathbb P^2_{\mathbb Q}\), \(d=3\).

There is an essential convention to repair. In much of arithmetic geometry \(h_{\mathscr L}\) denotes a **logarithmic** Weil height. A bound \(h_{\mathscr L}\leq B\) then produces exponential, not polynomial, growth in \(B\). Throughout this report, \[H_{\mathscr L}:=\exp(h_{\mathscr L}) \] is the multiplicative height and the bound is \(H_{\mathscr L}\leq B\), equivalently \(h_{\mathscr L}\leq\log B\). If the source's inequality is read literally with logarithmic \(h_{\mathscr L}\), every occurrence of \(B^\alpha\) below becomes \(\exp(\alpha B)\).

Replacing a metric by an equivalent one preserves power and logarithmic exponents but can change the leading constant. Thus no numerical \(c\) is meaningful until the metric and the exceptional set are specified.

Cyclic triple covers ordered by genus

P / partially_solved | AIM 研讨会问题汇编

Question 5. For cyclic triple covers of P1 can we recover (A) and (B) while counting by genus?

It is Question 5 in the AIM problem-session document for the January 2014 workshop *Arithmetic statistics over finite fields and function fields*. The immediately surrounding questions ask which ways of counting field extensions satisfy Principles (A) and (B), which automorphism groups give the cleanest formulas, whether conditioning on ramification helps, and whether an analogous assertion fails for \(\mathbb Z/4\mathbb Z\)-extensions counted by genus.

There is a source defect that matters mathematically: neither the three-page problem document nor the workshop report defines the labels (A) and (B). I therefore do **not** assign a letter to either assertion below. The strongest source-supported reconstruction comes from two facts:

1. the workshop report says that the group working on Question 5 aimed to use Wood's results on local behavior of abelian extensions to count \(\mathbb Z/3\mathbb Z\)-covers by the whole genus; and 2. Wood's cited paper foregrounds exactly two properties: conditional Chebotarev proportions for unramified splitting and independence of local specifications at distinct places.

Accordingly, this report uses the neutral names:

- **Chebotarev property:** conditional on a place being unramified, its splitting behavior has the usual Chebotarev proportions; - **independence property:** prescribed local behaviors at any fixed finite set of places become independent in the genus limit.

This is a high-confidence reconstruction of the intended mathematical pair, but the assignment of these properties to the letters (A) and (B) remains unverified. A third closely related feature, the explicit local mass formula, is recorded as part of the same theorem rather than silently identified with either letter.

The published work arising from the workshop makes the relevant ensemble precise: fix \(\mathbb F_q\) with \(q\equiv 1\pmod 3\), let \(g\to\infty\), and count the full moduli space \(\mathcal H_{g,3}\) of cyclic degree-three Galois covers of \(\mathbb P^1\) using the stack weights \(1/|\operatorname{Aut}(C)|\) specified in that paper.

Degree sets on Skorobogatov's bielliptic surface

P / partially_solved | AIM 研讨会问题汇编

For a nice variety \(X/k\),

$$ \mathcal D(X/k)=\{d>0:X\text{ has a closed point of degree }d\}, $$

\(\delta(X/k)\) is the set of \(d>0\) for which degree-\(d\) closed points are Zariski dense, and

$$ \mathcal P(X/k)=\bigcup_{[k':k]<\infty}\delta(X/k'). $$

The question concerns Skorobogatov's bielliptic surface \(S/\mathbb Q\), for which

$$ S(\mathbb A_{\mathbb Q})^{\operatorname{Br}}\ne\varnothing, \qquad S(\mathbb Q)=\varnothing. $$

$$ p(x)=x^2+1,\qquad q(x)=x^2+2,\qquad g(t)=3(t^4-54t^2-117t-243). $$

The intended \(S\) is the smooth projective model of

$$ p(x)y^2=q(x)z^2=g(t). \tag{1} $$

Equivalently, after setting \(\widetilde y=p(x)y\) and \(\widetilde z=q(x)z\), an affine chart is

$$ \widetilde y^2=g(t)p(x),\qquad \widetilde z^2=g(t)q(x). \tag{2} $$

Distribution and upper bound of mimic numbers

P / partially_solved | Open Problem Garden

Problem

Let the notation $a|b$ denote " a divides b ". The mimic function in number theory is defined as follows [1].

Definition For any positive integer $\mathcal{N} = \sum_{i=0}^{n}\mathcal{X}_{i}\mathcal{M}^{i}$ divisible by $\mathcal{D}$, the mimic function, $f(\mathcal{D} | \mathcal{N})$, is given by,

$$f(\mathcal{D} | \mathcal{N}) = \sum_{i=0}^{n}\mathcal{X}_{i}(\mathcal{M}-\mathcal{D})^{i}$$

By using this definition of mimic function, the mimic number of any non-prime integer is defined as follows [1].

Definition The number m is defined to be the mimic number of any positive integer $\mathcal{N} = \sum_{i=0}^{n}\mathcal{X}_{i}\mathcal{M}^{i}$, with respect to $\mathcal{D}$, for the minimum value of which $f^{m}(\mathcal{D} | \mathcal{N}) = \mathcal{D}$.

Given these two definitions and a positive integer $\mathcal{D}$, find the distribution of mimic numbers of those numbers divisible by $\mathcal{D}$.

Again, find whether there is an upper bound of mimic numbers for a set of numbers divisible by any fixed positive integer $\mathcal{D}$.

00323 | OWR-1703867-009

Effective Enumeration of Rational Points on Curves

O / open | Oberwolfach 报告问题汇编

Given equations for a smooth geometrically irreducible projective curve C of genus at least 2 over a number field F, is there an algorithm that produces the complete list of points in $C(F)$?

来源字段：https://doi.org/10.4171/owr/2020/20

00324 | OWR-14299908-005

Effective G-Function Bounds for Unlikely Intersections

P / partially_solved | Oberwolfach 报告问题汇编

Determine the strongest fully explicit G-function height bounds for unlikely intersections in algebraic tori and abelian varieties. In particular, extend the current explicit bounds from line sections in $\mathbb G_m^3$ to arbitrary algebraic curves in $\mathbb G_m^n$, and develop analogous explicit bounds for curves in powers A^n of a simple abelian variety A.

来源字段：https://doi.org/10.4171/owr/2026/3

00325 | OWR-14299578-006

Effective Mordell Bounds for Rational Points

O / open | Oberwolfach 报告问题汇编

Give an effective form of the Mordell conjecture: for every smooth projective curve C of genus at least two over a number field K, compute an explicit bound for the heights and number of points in $C(K)$ from effective arithmetic data of C and K.

来源字段：https://doi.org/10.4171/owr/2025/52

00326 | OWR-1104-003

Effective Mordell-Vojta Conjecture

O / open | Oberwolfach 报告问题汇编

Let K be a number field and X/K a smooth projective curve. For every $\varepsilon>0$, does there exist $\kappa(\varepsilon)$ such that $h_\omega(P)\leq(1+\varepsilon)d(P)+\kappa(\varepsilon)$ for every algebraic point $P\in X(\overline K)$, where h_ω is the normalized dualizing-sheaf height and $d(P)$ is the logarithmic discriminant of $K(P)$?

来源字段：https://doi.org/10.4171/owr/2005/43

00327 | OWR-14603-031

Effective Siegel Theorems for Genus-Two Curves

O / open | Oberwolfach 报告问题汇编

For a genus-two curve C over a number field k and a nonconstant $\phi\in k(C)$, can Siegel's theorem on S-integral points with respect to ϕ be made effective in general, i.e. can one give an algorithm or explicit bound for all such points?

来源字段：https://doi.org/10.4171/owr/2016/21

00328 | OWR-11784-002

Effective Thue-Mahler Equations over Finitely Generated Domains

P / partially_solved | Oberwolfach 报告问题汇编

Let $F\in A[X,Y]$ be a binary form of degree at least 3 without multiple factors over a finitely generated domain A. Given that $F(x,y)\in A^*$ has only finitely many solution classes under simultaneous multiplication by units, can representatives (x_i,y_i) of every class be determined effectively?

来源字段：https://doi.org/10.4171/owr/2012/22

00329 | AIM-ANALYTIC_NUMBER_THEORY-0023

Efficient correlation with Liouville and entropy

P / partially_solved | AIM 研讨会问题汇编

Is there a bounded sequence $a(n)$ such that each $a(n)$ is computable in time $O(\log^A n)$ for some fixed $A > 0$ and such that \[\left| \sum_{n \leq X} \lambda(n) a(n) \right| > \epsilon X \] for all X and some fixed $\epsilon > 0$? Can we say something about the Furstenberg systems of such an $a(n)$? In particular, do they have positive entropy?

来源字段：http://aimpl.org/sarnakconjecture/1/

00330 | OWR-12583-004

Efficient Relation Generation for Curve Class Groups

O / open | Oberwolfach 报告问题汇编

Can the heuristic expected running time $$\exp\!\left(O\!\left(\max\{\log q,\,n(\log q)^{1/2}\}\right)\right)$$ for relation generation in the discrete-logarithm algorithm be achieved for broader families of elliptic curves, or for curves of any fixed genus, by weakening or removing the hypothesis $n\leq C\log q$?

Erdős Problem #944

P / partially_solved | Erdős 问题

A critical vertex, edge, or set of edges, is one whose deletion lowers the chromatic number.

Let $k\geq 4$ and $r\geq 1$. Must there exist a graph G with chromatic number k such that every vertex is critical, yet every critical set of edges has size $>r$?

For a nice variety X/k, it asks how far

$$\min \delta(X/k),\qquad \operatorname{uni.irr}(X),\qquad \operatorname{cov.gon}(X),\qquad \operatorname{conn.cov.gon}(X)$$

can differ, where

$$\delta(X/k)=\{d\geq 1:\{x\in X\text{ closed}:[k(x):k]=d\}\text{ is Zariski dense}\}.$$

The record specifically suggests $X=Y\times\mathbb P^1$, asserting that the covering gonality is 1 while the minimum density degree is unchanged.

There is a transcription error in the two displayed gonality definitions in the record. They minimize d subject to

$$\operatorname{gon}(\mathcal C_b)\geq d.$$

Read literally, $d=1$ works for every family of integral curves, so this would make both minima vacuous whenever the relevant family exists. The standard definition of Bastianelli--De Poi--Ein--Lazarsfeld--Ullery is the **least gonality of a covering family** (respectively a family connecting two general points): the general fiber has gonality d, equivalently at most d. All gonality assertions below use this standard reconstructed definition. This reconstruction is also consistent with the source remark about $Y\times\mathbb P^1$.

Unless explicitly stated otherwise, k is a number field and a nice variety is smooth, projective, and geometrically integral over k. Covering and connecting gonality are taken geometrically, as in the standard literature. When a k-defined version of unirational degree is used, it is denoted $\operatorname{uni.irr}_k$.

Exceptional Galois Points on Modular Curves

O / open | Oberwolfach 报告问题汇编

Extend the Khawaja-Siksek finiteness theorem for primitive algebraic points from symmetric and alternating Galois groups to other families of simple and almost simple groups. More specifically, let N be large and let $j:X_0(N)\to X(1)$ be the usual map. Hilbert irreducibility gives a thin set $S\subset X(1)(\mathbb{Q})$ such that, for $\alpha\in X(1)(\mathbb{Q})\setminus S$, the fiber $j^{-1}(\alpha)$ has Galois group $\mathrm{PGL}_2(\mathbb{Z}/N\mathbb{Z})$. Is S finite or infinite? If it is infinite, which Galois groups occur infinitely often? Is there an infinite family of algebraic points on $X_0(N)$ with Galois group $\mathrm{PGL}_2(\mathbb{Z}/N\mathbb{Z})$ that does not arise from j?

Finite asymptotic certificates and a cusp-width span bound for fixed-matrix Nahm sums

P / partially_solved | AIM 研讨会问题汇编

Problem 2.1. Given a particular A, can we bound the number of possible B? Similarly, given a particular A, can we bound the dimension of the vector space determined by the B?

The bounds may or may not be effective.

The statement is not self-contained.

* \(r\geq 1\), \(A\in M_r(\mathbb Q)\) is symmetric positive definite; * \(B\in\mathbb Q^r\), \(C\in\mathbb Q\); * \(q=e^{2\pi i\tau}\), \((q)_m=\prod_{j=1}^m(1-q^j)\), and \((q)_0=1\); * the associated Nahm sum is \[f_{A,B,C}(\tau)=F_{A,B,C}(q) :=\sum_{n\in\mathbb Z_{\geq0}^r} \frac{q^{\frac12n^tAn+B^tn+C}} {(q)_{n_1}\cdots(q)_{n_r}}. \]

The preceding paragraph calls \((A,B,C)\) a choice for which this function is modular. In current terminology it is a **modular triple**. Thus “possible \(B\)” is most naturally read as \[\mathcal B_A:=\{B\in\mathbb Q^r:\text{there is }C\in\mathbb Q \text{ such that }(A,B,C)\text{ is a scalar modular triple}\}. \] The 2024 work of Wang--Zhang confirms the natural interpretation of “the vector space determined by the \(B\)” as the span of the Nahm sums with the same \(A\), often organized as a vector-valued modular function.

There remains an ambiguity that matters: the workshop does not prescribe one modular group, multiplier, or level for all \(B\). A dimension bound in a fixed space of modular functions therefore needs a **common finite-index group** hypothesis. The result below states that hypothesis explicitly. It does not silently assume a uniform level.

Generic minimum density degree and a quartic counterexample

P / partially_solved | AIM 研讨会问题汇编

The following is asked as an analogue of a result due to Debarre and Klassen (arXiv:alg-geom/9210004).

Let $X_d\subset\mathbb P^3_k$ (k a number field) be a smooth surface of degree d. Are the degree $\le d-3$ points not Zariski dense? What is $\min\delta(X_d/k)$?

You probably want to assume that d is sufficiently large.

One can also ask this question for the generic degree d hypersurface, defined over the field of rational functions in the appropriate number of variables.

For d small, can we construct surfaces such that the degree $\le d-3$ points *are* Zariski dense?

Let $f=\sum_{n\geq1}a(n)q^n$ be a normalized eigenform of weight $l+m+4$ for $\operatorname{SL}_2(\mathbb Z)$, and let ℓ be a sufficiently large prime in its coefficient field dividing $\Lambda(f,l+3)$. Must there exist a Siegel modular eigenform F of weight $(l-m,m+3)$ whose Hecke eigenvalues satisfy $\lambda(p)\equiv p^{m+1}+a(p)+p^{l+2}\pmod{\ell^{\prime}}$ for a prime $\ell^{\prime}$ above ℓ? If $f\in S_{l+m+4}(\Gamma_0(2))^{\mathrm{new}}$ and $g\in S_{l-m+2}(\Gamma_0(2))^{\mathrm{new}}$, must there exist a Siegel eigenform $F\in S_{l-m,m+3}(\Gamma_2[2])$ with $L(F,s)=L(f,s)L(g,s-m-1)$, with multiplicity five when the two newforms have the same w_2-eigenvalue and multiplicity one otherwise? Does the corresponding level-four lifting occur with multiplicity five in $S_{l-m,m+3}(\Gamma_2[2])$?

Harder Congruences for Holomorphic Jacobi Forms

P / partially_solved | Oberwolfach 报告问题汇编

别名：Conditional Harder-Congruence Theorem [OWR-17300-007]

Assume $k\geq 3$, $j\geq 0$, and $j\equiv 2\pmod 4$. For a Hecke-eigen cusp form f in $S_{2k+j-2}(\Gamma_1)$, let ϕ_0 be the corresponding degree-one Jacobi form and $E(\phi_0)$ its degree-two Klingen lift. The holomorphic Jacobi-form version of Harder's conjecture asserts that there is a degree-two holomorphic Jacobi form Φ outside the lift and a prime ideal $\mathfrak l$ dividing $L^{\mathrm{alg}}(k+j,f)$ such that the Hecke eigenvalues of Φ and $E(\phi_0)$ are congruent modulo $\mathfrak l$ for every integral Hecke operator.

01087 | AIM-ALGEBRAIC_NUMBER_THEORY-0061

Heegner transfer on a split genus-two locus

P / partially_solved | AIM 研讨会问题汇编

1. (C. Hall) We know how to construct points on an elliptic curve E over $\mathbb F_q(T)$ when the analytic rank is 1 by using (Drinfel'd) Heegner points. What if X is a hyperelliptic curve over $\mathbb F_q(T)$ of higher genus? Is there any way of constructing the points on the Jacobian of X that ought to be there?

Comments. 1) We have a lot of explicit examples when the analytic rank is 1. (C. Hall)

2) If we start with any surface S over $\mathbb F_q$ we can, via Lefschetz fibration, make it into a curve over $\mathbb F_q(T)$. Typically (since the rank of H^2 is even), one has two Tate classes. One of these is given by hyperplane sections; can we “see” or construct the other one? This question is like the one above, but without requiring C to be hyperelliptic. So, in some sense, the problem is almost as hard as the problem of treating general surfaces. (C. Schoen)

01090 | AIM-ALGEBRAIC_NUMBER_THEORY-0085

Height-window bounds and modern status for random hypersurface solubility

P / partially_solved | AIM 研讨会问题汇编

$$\mathcal F_{d,n}(H)=\{f\in\mathbb Z[x_0,\ldots,x_n]_d:\max_I |a_I|\le H\},\qquad m=\binom{n+d}{d},$$

where $f=\sum_Ia_Ix^I$ is homogeneous of degree d. Then

$$N_{\rm tot}(H)=\#\mathcal F_{d,n}(H)=(2\lfloor H\rfloor+1)^m,$$

$N(H)$ counts the members having a nonzero integral zero (equivalently a rational point on $f=0\subset\mathbb P^n$), and $N_{\rm loc}(H)$ counts those having a point over every completion of $\mathbb Q$.

1. If $d>n+1$, does $N(H)/N_{\rm tot}(H)\to0$, and does this follow from Lang's conjectures? 2. Is $N_{\rm loc}(H)/N_{\rm tot}(H)$ bounded below by a positive constant? 3. For a random plane cubic, how likely is a rational point? 4. For cubic surfaces, and more generally in the Fano range $d\le n$, is $$\frac{N(H)}{N_{\rm tot}(H)}\sim \frac{N_{\rm loc}(H)}{N_{\rm tot}(H)}?$$

The PDF literally says "max coefficient". This reconstruction is verified by the definitions in Poonen--Voloch, the update linked from the AIM record. Their paper also makes precise that counting primitive equations or projective hypersurfaces instead of all integral equations does not alter the limiting ratios.

来源字段：https://aimath.org/WWN/qptsurface2/qptsurface2.pdf

01091 | AIM-ALGEBRAIC_NUMBER_THEORY-0052

Heilbronn sums as exact Fourier quadrature

P / partially_solved | AIM 研讨会问题汇编

The PDF literally prints

\[\sum_{x\bmod p} \exp\!\left(\frac{2\pi i x^p(1+pt)}{p^2}\right) = \sum_{x\bmod p} \exp\!\left(\frac{2\pi i x^p}{p^2}\right) \cdot \exp\!\left(\frac{2\pi i pt}{p^2}\right), \]

and then asks why these sums, as t varies, "seem to approximate ... the (push forward of) Haar measure better than expected."

There is a source-level error in the displayed equality. The last factor on the printed right-hand side is independent of x, so that side is merely $e_p(t)$ times the sum at $t=0$. Direct algebra instead gives

\[e_{p^2}\!\left(x^p(1+pt)\right) =e_{p^2}(x^p)e_{p^2}(ptx^p) =e_{p^2}(x^p)e_p(tx), \tag{1.1} \]

where $e_N(u)=\exp(2\pi i u/N)$ and $x^p\equiv x\pmod p$. Thus the algebraically forced correction is

\[S_p(t):=\sum_{x\bmod p}e_{p^2}\!\left(x^p(1+pt)\right) =\sum_{x\bmod p}e_{p^2}(x^p)e_p(tx). \tag{1.2} \]

The PDF does **not** specify a range for t, a normalization, the compact group carrying Haar measure, or the pushforward map. The left side is periodic in $t\pmod p$, so the effective range is $t\in\mathbb F_p$. The following is the minimal natural reconstruction compatible with (1.2): the right side samples one real Laurent polynomial at all p-th roots of unity, and the comparison measure is the pushforward of normalized Haar measure on the unit circle by that same polynomial. A different random-matrix Haar target cannot be recovered from the PDF alone.

Iwasawa Main Conjecture for Dihedral Ring Class Towers

P / partially_solved | Oberwolfach 报告问题汇编

Let K be a finite extension of the imaginary quadratic field k inside its cyclotomic extension, and let F be the maximal totally real subfield of K. Assume that the root number of $L(E/k,s)$ is $+1$, that $p\geq5$, that the representation on $E[p]$ has image $\operatorname{GL}_2(\mathbb{F}_p)$, that p does not divide the minimal modular degree, and that $E[p]$ is an irreducible I_v-module whenever $v^2\mid N\mathcal{O}_F$ and $p\mid\operatorname{N}(v)+1$. For the ring-class tower $K[p^\infty]$, does $(L_p(\phi_F,K[p^\infty]))=(\operatorname{char}_{\Lambda(J_K(\infty))}X(E/K[p^\infty]))$ hold? Torsion and the inclusion from the p-adic L-function ideal into the characteristic ideal are known; the open content is the reverse divisibility.

Local R-equivalence and a geometric Brauer obstruction to eventual universal R-triviality

P / partially_solved | AIM 研讨会问题汇编

Question 10 (Colliot-Thélène). Are there results at the level of number fields arising from the techniques of rationally connected varieties? For example, recently Kollár got nice results over local fields: if \(X/k\) is a projective variety, we say \(P,Q\in X(k)\) are \(R\)-equivalent if one can link them by a chain of curves of genus zero over \(k\); if \(X\) is smooth with \(k\hookrightarrow\mathbb C\), then \(X\) is rationally connected if \(X(\mathbb C)/R\) is a single point. Kollár proved that if \(k\) is a local field and \(X/k\) is rationally connected, then \(X(k)/R\) is finite. Kollár and Szabó proved that if \(k\) is a number field and \(X/k\) is rationally connected, then \(X(k_v)/R\) is trivial for almost all \(v\).

01204 | AIM-ANALYTIC_NUMBER_THEORY-0106

Local singular series and multiplicative-order correlations for Elliott's shifted-prime ratio

P / partially_solved | AIM 研讨会问题汇编

`ak = p + 1` `q + 1 (2)`

In particular, it contains the lines

and renders the proposed bound with missing comparison and epsilon symbols. Direct inspection of the typeset AIM problem PDF verifies that equation (2) is

\[a^k=\frac{p+1}{q+1}, \tag{1} \]

where \(a>1\) is fixed, \(p,q\) are primes, and \(k\) is an integer. The PDF states Elliott's range as \(2\leq k\leq \log q\), and the proposed improvement as

\[k\ll (\log q)^{1/2+\varepsilon}. \tag{2} \]

Thus the mathematical task is to improve the size of an exponent that is allowed to vary from solution to solution; it is **not** the much stronger assertion that a prescribed fixed \(k\) gives infinitely many prime pairs.

Put \(A=a^k\). Equation (1) is exactly the simultaneous-primality problem

\[L_1(n)=n,\qquad L_2(n)=An+A-1, \tag{3} \]

with \(n=q\) and \(p=L_2(q)\). Equivalently, on writing \(m=q+1\), the two forms are \(m-1\) and \(a^k m-1\).

There is a minor source discrepancy worth recording. The local calculations below are made from (1), using (3). The same local root counts apply to the all-plus family because multiplying every forbidden residue by \(-1\) does not change their number.

Merged GPY and Gaussian-prime questions with a finite-direction occupancy reduction

O / open | AIM 研讨会问题汇编

12. Limits of the GPY method.

• H. Helfgott noted that it seems that the GPY method is by nature a lower bound method and will most likely never yield an asymptotic formula for the number of primes with a given spacing. He asked those who were well-versed in the GPY method whether this is indeed so and also whether the GPY method is capable of producing a right-order lower bound.

• J. Pintz replied that an asymptotic formula of any kind appears to be out of the reach of the method. He also noted that the method could potentially yield a "right-order lower bound", but that that will involve considerable technical di ffi culties. Some ideas in that direction were sketched in C. Yildirim's talk. It should be noted that in this context, a "right-order lower bound" means that one can show that a positive proportion of the k-tuples we consider contain at least two primes. 313. Distances between Gaussian primes. Several members of the audience asked whether the GPY method can be adapted to study small distances between Gaussian primes. T.D. Wooley remarked that such an adaptation should be straightforward.

Mock forms as boundary pieces of twisted Nahm sums

P / partially_solved | AIM 研讨会问题汇编

Extend the Nahm-sum, Bloch-group, and asymptotic framework so that it can recognize mock modular \(q\)-hypergeometric series, their shadows, and their controlled failure of holomorphic modularity.

The pronoun “this” is resolved by the immediately preceding source context. Section 2 of the 2010 AIM problem list introduces

\[f_{A,B,C}(\tau)= \sum_{\boldsymbol n\in\mathbb Z_{\geq0}^r} \frac{q^{\frac12\boldsymbol n^tA\boldsymbol n+B^t\boldsymbol n+C}}{(q;q)_{n_1}\cdots(q;q)_{n_r}}, \qquad q=e^{2\pi i\tau}, \]

where \(A\) is rational, symmetric, and positive definite, \(B\in\mathbb Q^r\), and \(C\in\mathbb Q\). The section discusses Nahm's proposed connection between modularity and the Bloch-group element obtained from the Nahm equations. Problems 2.1--2.4 concern the possible \(B\)'s, asymptotic jumps, higher-rank modular examples, and a Bailey-pair/Bloch-group dictionary; Problem 2.6 asks about quantum dilogarithms.

Thus the recovered task is:

Find a (conjectural) asymptotic formula for \[\sum_{n \le x} d_{k_1}(n+h_1) d_{k_2}(n+h_2) \cdots d_{k_r}(n+h_r) \] where $(k_1, \ldots, k_r) \in \mathbb{N}^r$ and $h_1, \ldots, h_r$ are distinct positive integers with $r \ge 3$. This would be analogous to the. conjectural asymptotic formula for \[\sum_{n \le x} \Lambda(n+h_1) \cdots \Lambda(n+h_r) \] that arises from the Hardy-Littlewood conjectures. Note that Ng-Thom and Tao have used different probabilistic arguments to derive conjectures in the case $r=2$.

Let g be a primitive cusp form of weight k for $\Gamma_{0}(N)$. Assume that g is arithmetically normalized so that its first Fourier coefficient $a_g(1)=1$ and write $g(z)=\sum_{n=0}^{\infty}\lambda_{g}(n)n^{\frac{k-1}{2}}e(nz)$. Let $X, Y, P\geq 1$, and let $F(x,y)$ be a smooth weight function supported on $(X/4,4X]\times[Y/4,4Y]$ satisfying \[x^iy^j\frac{\partial^{i}}{\partial{x^i}}\frac{\partial^{j}}{\partial v^j}f(u,v)\ll P^{i+j}\] for all $i,j\geq0$. Consider the shifted convolution sum \[D_{g}(\ell_1,\ell_2;h)=\sum_{\ell_1m\pm \ell_2n=h}\lambda_g(n)\lambda_g(m)F(\ell_1m,\ell_2n),\] where ℓ_1 and ℓ_2 are coprime. Harcos [Harcos] proved an asymptotic upper bound for $D_{g}(\ell_1,\ell_2,h)$ where the implicit constants depend on g. Blomer and Harcos [BH] established an asymptotic bound for an averaged version of this shifted convolution sum in which the implicit constants also depend on g.

Conrey *el al* made the conjecture \[I_k(T) = TP_{k^2}(\log T) + O(T^{\frac{1}{2} + \varepsilon}) \] where P_{k^2} is a certain degree k^2 polynomial. Let \[E_k(T) = I_k(T) -TP_{k^2} (\log T) \] denote the error term. Since the publication of [CFKRS] there has been some debate on what should be the correct conjectural size of $E_k(T) $. Note that it is widely believed that $E_1(T) = O(T^{\frac{1}{4}+\varepsilon})$ and $E_2(T) = O(T^{\frac{1}{2}+\varepsilon})$ are best possible. There are omega results for both of these cases. It would be desirable to come up with a conjecture for optimal constants θ_k such that \[E_k(T) = O(T^{\theta_k+\varepsilon}) \] holds for $k \in\mathbb{N}$. N. Ng believes that $\theta_1=\frac{1}{4}$ and $\theta_2=\frac{1}{2}$ are the correct answers for $k=1,2$. What about $k \ge 3$? Both Ivic and Motohashi suggested $\theta_3 = \frac{3}{4}$. Can the Multiple Dirichlet Series method be used to derive an appropriate conjecture? (Work in progress of Baluyot and Cech is studying this.) \\ (Nathan Ng, Lethbridge)

Improve Chandee's [Ch, Theorem 1.2]. \begin{theorem} Let k_i be positive real numbers. Let $\alpha_i=\alpha_i(T)$ be real-valued functions of T such that $\alpha_i =o(T)$. Assume that $\lim_{T\rightarrow \infty} \alpha_i\log T$ and $\lim_{T\rightarrow \infty} (\alpha_i-\alpha_j)\log T$ exist or equal $\pm \infty$. Assume that for $i\neq j$, $\alpha_i\neq \alpha_j$ and $\alpha_i-\alpha_j =O(1)$. Then the Riemann Hypothesis implies that for T sufficiently large, one has $$ M_{**k**}(T, **\alpha**)\ll_{**k**,\varepsilon} T(\log T)^{k_1^2 + \cdots k_m^2 +\varepsilon} \prod_{i<j} \left(\min\left\{\frac{1}{|\alpha_i-\alpha_j|}, \log T \right\}\right)^{2k_ik_j} $$ where \[M_{**k**}(T, **\alpha**) = \int_{0}^{T} |\zeta(\tfrac{1}{2} + (t+\alpha_1))|^{2 k_1} \cdots |\zeta(\tfrac{1}{2} + (t+\alpha_m)|^{2 k_m} dt. \] \end{theorem} Use Harper's method [Ha] to remove the ε. Note that the case of two shifts ($m=2$ and $k_1=k_2$) has been dealt with in [NSW]. \\ (N. Ng, Lethbridge)

Monotone means and a Poisson moving-target limit for complete-intersection curves

P / partially_solved | AIM 研讨会问题汇编

Question 10 (Melanie Matchett Wood). Look at complete intersections, and some examples with a moving target space.

The record is exactly as terse as this quotation: it does not specify an ensemble, statistic, asymptotic variable, or formal conjecture. The nearby questions ask for the distribution of the number of $\mathbb F_q$-points on curves as genus grows and for “principle (A)” for tri-canonically embedded curves. The AIM workshop report supplies the missing common theme: Wood's talk asked when the number of points on curves in a family has a distribution given by a sum of independent identically distributed random variables. The source file itself never defines its labels “Principles (A) and (B),” and no definition was recovered from the AIM report. Consequently, this report does **not** assign those labels to a reconstructed statement.

The closest precise complete-intersection model is the one of Bucur--Kedlaya. Let $X\subseteq \mathbb P^r_{\mathbb F_q}$ be smooth of dimension m, let $$ S_d=H^0(\mathbb P^r,\mathcal O(d)),\qquad \mathbf f=(f_1,\ldots,f_k)\in S_{d_1}\times\cdots\times S_{d_k}, $$ choose the **ordered tuple of equations** uniformly, and condition $X\cap H_{f_1}\cap\cdots\cap H_{f_k}$ to be smooth of dimension $m-k$. The statistic is its number of projective $\mathbb F_q$-points. For fixed X,q,m,k, and large degrees, the precise local-independence principle is that this point count converges to a sum of $\#X(\mathbb F_q)$ independent Bernoulli variables.

At a rational point, put $$ L(q,m,k)=\prod_{j=0}^{k-1}(1-q^{-(m-j)}). $$ The probability that the first jets of the equations are locally compatible with smoothness is $$ a(q,m,k)=1-q^{-k}+q^{-k}L(q,m,k), $$ and, conditional on that local event, the point lies on the intersection with probability $$ \rho(q,m,k)=\frac{q^{-k}L(q,m,k)}{1-q^{-k}+q^{-k}L(q,m,k)}. \tag{1.1} $$ Thus the recovered fixed-target principle is a rigorously proved **fiberwise/local asymptotic independence statement**, not an assertion about uniformly sampled isomorphism classes of curves.

“Moving target space” is naturally read as a triangular array in which the ambient X_i, hence $N_i=\#X_i(\mathbb F_q)$, also varies. This reading is confirmed by the paper of Kurlberg--Wigman cited by Bucur--Kedlaya: they vary projective surfaces having increasingly many rational points and obtain Gaussian point-count statistics for high-degree curve sections. The present report also studies the explicit moving targets $X_n=\mathbb P^n$, with the codimension moving simultaneously to $k_n=n-1$. This second shape is in a different probabilistic regime: the number of ambient points grows, but the local hit probability decays at the compensating rate, leading to a Poisson rather than a Gaussian limit.

Odd Brauer torsion on K3 surfaces: status and a Picard-rank filter

P / partially_solved | AIM 研讨会问题汇编

The record is Problem 8 in the AIM workshop list *Rational and integral points on higher-dimensional varieties*, dated May 28, 2014. I interpret \(\operatorname{Br}(X)[u]\) as the subgroup killed by the odd integer \(u\).

1. Can a K3 surface \(X/\mathbb Q\) have odd-order torsion in \(\operatorname{Br}(X)\) that obstructs the Hasse principle? Can this happen already in \[\operatorname{Br}_1(X)=\ker\bigl(\operatorname{Br}(X)\to \operatorname{Br}(\overline X)\bigr)? \] 2. For a smooth quartic K3 surface \(X\subset \mathbb P^3\), does \[\bigl(\operatorname{Br}(X)/\operatorname{Br}(\mathbb Q)\bigr)[2]=0 \] imply the Hasse principle? What happens to weak approximation? 3. What is the corresponding situation for a degree-six K3 surface \(X\subset \mathbb P^4\)? In the K3 context this is the genus-four polarization; for a smooth nondegenerate model it is the familiar quadric--cubic complete intersection.

The source also sketches a zero-cycle argument: an odd class on a quartic can be made orthogonal to local zero-cycles of degree one, and the degree-one zero-cycle conjecture invoked by Colliot-Thélène would then produce a global zero-cycle of degree one. The remaining issue is that index one does not by itself produce a rational point.

Odd-degree Jacobian mean and its arithmetic correction

P / partially_solved | AIM 研讨会问题汇编

Question 17 (John Voight). What is the average number of points on the Jacobian of a hyperelliptic curve?

It is Question 17 in the AIM workshop list *Arithmetic statistics over finite fields and function fields*. The statement does not specify the ground field, genus, family, limiting regime, or weighting. “Points” must also be interpreted: over an algebraic closure a positive-dimensional Jacobian has infinitely many points, whereas over a finite field its set of rational points is finite.

Question 16 immediately before this record begins “Fix \(q\), let \(g\to\infty\),” and Question 18 immediately after it again begins “Fix \(q\).” This makes the following a well-motivated, but not textually forced, reconstruction:

- \(q\) is an odd prime power and \(A=\mathbb F_q[T]\); - \(\mathcal H_{2g+1,q}\) is the set of monic square-free \(D\in A\) of degree \(2g+1\); - \(C_D\) is the smooth projective curve with affine model \(y^2=D(T)\), and \(J_D=\operatorname{Jac}(C_D)\); - the desired average is \[M_g(q):=\frac{1}{\#\mathcal H_{2g+1,q}} \sum_{D\in\mathcal H_{2g+1,q}}\#J_D(\mathbb F_q), \qquad g\longrightarrow\infty \] with \(q\) fixed.

Here \(\#\mathcal H_{2g+1,q}=(q-1)q^{2g}\). Odd degree marks the unique rational point at infinity and is the standard “imaginary hyperelliptic” equation ensemble. It is not interchangeable with any of the following:

- uniform isomorphism classes of curves; - stack weighting by \(1/\#\operatorname{Aut}(C)\); - even-degree equations; - characteristic-two Artin--Schreier models; - fixed genus with \(q\to\infty\).

The exact source wording is therefore preserved, and all results below state their weighting and limiting regime explicitly.

Primitive balanced proper triples of sums of two squares

P / partially_solved | AIM 研讨会问题汇编

19. Triples in prime-like sequences.

• C. Elsholtz asked whether it is possible to find infinitely many triples \(s_n,s_{n+1},s_{n+2}\), with \(s_{n+2}-s_n\) bounded, in sequences that are commonly considered to be similar to but more manageable than the primes (e.g., integers that are sums of two squares).

• K. B. Ford noted that for sums of two squares the problem is trivial, because of triples of the form \(n^2,n^2+1,n^2+4\), for example.

• J. B. Friedlander suggested that such trivialities can be avoided by requiring that the two squares be of comparable sizes. S. W. Graham and T. D. Wooley proposed another option: produce “many” gaps.

• R. C. Vaughan proposed considering the more general question of triples of values of norm-forms.

Radial Laplace obstruction and an exact C-law for Stokes jumps

P / partially_solved | AIM 研讨会问题汇编

Problem 2.2. Consider the Laplace transform of the q-hypergeometric series above. Note that the Mellin transform will not converge. Look at the properties, in particular the “jumps;” what can we say about the dependence on \(A,B,\) and \(C\)?

The exact AIM record asks:

\[f_{A,B,C}(\tau)=F_{A,B,C}(q) :=\sum_{n=(n_1,\ldots,n_r)^t\in\mathbb Z_{\geq0}^r} \frac{q^{Q(n)}}{(q)_{n_1}\cdots(q)_{n_r}}, \qquad Q(n)=\tfrac12n^tAn+B^tn+C, \]

where \(q=e^{2\pi i\tau}\), \((q)_m=\prod_{j=1}^m(1-q^j)\), and \((q)_0=1\).

The PDF does **not** specify a transform variable, a kernel, a contour, a subtraction of the dominant cusp exponential, or what “jumps” means. At least three readings are therefore possible:

1. the ordinary transform of the radial function \(R(t)=F(e^{-t})\); 2. a transform after the reciprocal change \(x=1/t\) and a subtraction or tail cutoff; 3. the Laplace step in Borel--Laplace summation of the formal cusp expansion, with “jumps” meaning lateral Stokes discontinuities.

The third reading is historically plausible: Costin--Garoufalidis used exactly this language for the related Kontsevich--Zagier series in work published immediately after the 2010 workshop. It is nevertheless not stated in the AIM PDF. The results below therefore separate the literal reading (an unconditional obstruction) from the Borel--Laplace reading (an exact parameter law conditional only on the relevant lateral sums existing).

01415 | AIM-ALGEBRAIC_NUMBER_THEORY-0117

Random hypersurfaces, local conditioning, and height transfer

P / partially_solved | AIM 研讨会问题汇编

In cleaned mathematical notation, the record asks three related but distinct questions.

1. For fixed degree d, projective dimension n, and number field K, order all degree-d hypersurfaces in $\mathbf P^n_K$ by coefficient height. What proportion has a K-point, and what proportion of the everywhere locally soluble members satisfies the Hasse principle? 2. For the diagonal family

\[a_1x_1^d+\cdots+a_sx_s^d=0,\qquad |a_i|\leq A, \]

determine the asymptotic of

\[A^{-s}\#\{\mathbf a:\ |a_i|\leq A, \ a_1x_1^d+\cdots+a_sx_s^d=0\text{ satisfies HP}\}. \]

Wooley and Venkatesh tentatively suggested a product of local densities, at least for $s\geq 3d+1$. 3. For plane cubics, relate such proportions to 3-Selmer groups of elliptic curves. Stoll predicted that, conditional on local solubility, the rational-point proportion should be 0, and Mazur asked for a decay exponent.

The official source confirms all three clauses and the threshold $s\geq 3d+1$ [AIM]. They must not be conflated: the diagonal locus is a zero-density subfamily of the full coefficient space, while plane cubics are a borderline genus-one family rather than a Fano family.

There is also a semantic trap in the phrase “satisfies HP.” For a single variety with no adelic point, the implication “local points imply a global point” is vacuously true. That cannot be the intended count, since the displayed local product measures locally soluble members. Throughout this report the quantitative HP assertion means

\[\#\{\text{globally soluble members}\} =\#\{\text{everywhere locally soluble members}\}+o(\#\Omega_H), \]

or, conditionally, that the locally soluble failure proportion tends to zero. Nonlocally soluble members are not reclassified as globally soluble by vacuous implication.

Real approximation and odd-kernel reduction for finite stabilizers

P / partially_solved | AIM 研讨会问题汇编

Problem 5. Harari: The following question is due to Borovoi: Consider weak approximation for $X=\operatorname{SL}_n/G$ over $\mathbf Q$, where G is a finite group scheme that is not necessarily constant. For example, is $X(\mathbf Q)$ dense in $X(\mathbf R)$? If G is constant, this is known to be true.

A variant is the following. Given $X=\operatorname{SL}_n/G$ with a constant finite group scheme G over a number field K with $r\geq 2$ real places $v_1,\ldots,v_r$, is $X(K)$ dense in $\prod_{j=1}^{r}X(K_{v_j})$? A formulation via non-abelian Galois cohomology is given in the case $K=\mathbf Q$ as follows: Is $H^1\!\left(\operatorname{Gal}(\overline{\mathbf Q}/\mathbf Q),G(\overline{\mathbf Q})\right) \longrightarrow H^1\!\left(\operatorname{Gal}(\mathbf C/\mathbf R),G(\mathbf C)\right)$ surjective?

Lucchini Arteche: The algebraic Brauer--Manin obstruction says nothing for this problem. Skorobogatov: The result is known for abelian G, due to Borovoi.

Settled Quadratic Polynomials and Markov Factorization Models

O / open | Oberwolfach 报告问题汇编

Is every irreducible quadratic polynomial $f\in\mathbb F_p[x]$ settled, meaning that the proportion of the degree of f^n occupied by f-stable irreducible factors tends to 1? More generally, does the large-n distribution of critical-orbit labels of the irreducible factors of f^n follow the long-term behavior of the appropriate Markov process?

01510 | AIM-ANALYTIC_NUMBER_THEORY-0110

Sparse-gap data do not determine Montgomery pair correlation

P / partially_solved | AIM 研讨会问题汇编

The record is Problem 10 in Angel Kumchev's notes from the December 2005 ARCC workshop *Gaps Between Primes*. The mathematically unambiguous repaired statement is as follows. Write

\[g_n=p_{n+1}-p_n. \]

Heath-Brown proved, under the Riemann hypothesis (RH) and the relevant local forms of Montgomery's pair-correlation conjecture, that

\[\liminf_{n\to\infty}\frac{g_n}{\log p_n}=0 \tag{1} \]

\[g_n\ll \sqrt{p_n\log p_n}. \tag{2} \]

The workshop asks (i) whether there is a converse to the implication leading to (1), and (ii) whether random-matrix theory can improve (2).

* “Di ff erences” is merely broken PDF font extraction and means “Differences.” * The control character U+001C in the last display is the Vinogradov symbol \(\ll\). * Most importantly, in the official PDF the radical overbar spans the entire product \(p_n\log p_n\). Thus (2) is \(g_n\ll\sqrt{p_n\log p_n}\), not \(g_n\ll\sqrt{p_n}\log p_n\). This is also Corollary 2 on p. 87 of Heath-Brown's paper. * The word “converse” is not expanded in the workshop notes. Its only reading consistent with “which ... would be unconditional post-GPY” is

\[\liminf g_n/\log p_n=0\quad\Longrightarrow\quad \text{Montgomery pair correlation} \tag{3} \]

(with whatever additional baseline hypothesis, such as RH, is stated). Indeed, GPY made the antecedent of (3) unconditional. The reverse reading would just repeat Heath-Brown's theorem and would not become a new unconditional pair-correlation result after GPY.

The workshop formulation says “RH and Montgomery's Pair Correlation Conjecture,” which is sufficient but stronger than Heath-Brown needs locally. For (1), his displayed conclusion on p. 88 follows when the pair-correlation asymptotic holds uniformly in a neighborhood of the frequency parameter \(\alpha=1\). For (2), bounded pair correlation in a neighborhood of \(\alpha=2\) suffices.

Sparse-orbit counterexamples and the exact Polynomial Chowla implication

P / partially_solved | AIM 研讨会问题汇编

1. **Polynomial Sarnak 1 (PS1).** If \((X,T)\) is minimal and has zero entropy, then \[\sum_{n\leq N}\lambda(n)f(T^{p(n)}x)=o(N). \] 2. **Polynomial Sarnak 2 (PS2).** If \(p\in\mathbb Z[t]\) is not a constant multiple of the square of a polynomial, then \[\sum_{n\leq N}\lambda(p(n))f(T^n x)=o(N). \] 3. **Polynomial Chowla (PC).** Under the same nonsquare condition, \[\sum_{n\leq N}\lambda(p(n))=o(N). \]

The question is whether the two Polynomial Sarnak statements are true and whether either follows from Polynomial Chowla. The source uses \(X\) both for the phase space and the summation cutoff; this report uses \(N\) for the cutoff. We extend \(\lambda\) to \(\mathbb Z\) by \(\lambda(-m)=\lambda(m)\) and \(\lambda(0)=0\), as is standard in the polynomial Chowla literature. Polynomial zeros affect only finitely many summands.

The archived source contains two later remarks. The name “Z. Liang” in one remark is a typo: the cited author is **Zhengxing Lian**, with Ruxi Shi. The source also states that PS2 follows from PC by the usual Chowla-to-Sarnak argument. Section 7 below supplies the algebraic and ergodic details needed to justify that assertion from the displayed, one-polynomial formulation of PC.

Tuple extension requires shifted correlation

P / partially_solved | AIM 研讨会问题汇编

18. From \(k\)-tuples to \((k+1)\)-tuples. J. B. Conrey asked whether it is possible to deduce the existence of prime \((k+1)\)-tuples from a version of the Elliott--Halberstam conjecture for prime \(k\)-tuples.

J. Pintz proposed to try to use EH for twin primes to obtain two pairs of twin primes that are close to each other.

The heading and first question are:

The two displayed estimates in the typeset PDF are, with their absolute values restored from the page layout,

\[\sum_{q\leq Q}\max_{(a,q)=1} \sum_{\substack{1\leq b\leq q\\(b,q)=1}} \left| \sum_{n\leq x/q}\varpi(qn+a)\varpi(qn+b) -MT(x,q;a,b) \right| \ll x^2(\log x)^{-A}, \tag{W1} \]

and Vaughan's suggested alternative

\[\sum_{q\leq Q}\max_{(a,q)=1} \left| \sum_{\substack{1\leq b\leq B\\(b,q)=1}} \left(\sum_{n\leq x/q}\varpi(qn+a)\varpi(qn+b) -MT(x,q;a,b) \right) \right| \ll Bx(\log x)^{-A}. \tag{W2} \]

Thus (W1)--(W2) are unweighted prime counts. The distinction matters because the cited papers use von Mangoldt weights.

The position of the absolute values is also essential. In (W1) one sums \(|E_{q,a,b}|\) over \(b\); in (W2) the sum over \(b\) is taken first and only then is its absolute value taken. Parentheses around the inner error in (W2) confirm this reading.

The PDF does **not** state:

- whether \(A>0\) is arbitrary; - how \(Q\) may depend on \(x\), and in particular no exponent of distribution; - whether \(B\) is fixed, grows, or is related to \(q,Q,x\); - the permitted dependence of the implied constant; or - a definition of \(MT(x,q;a,b)\).

Consequently (W1) and (W2) are templates, not complete quantified conjectures. The displayed range is exactly \(n\leq x/q\); floors and the lower endpoint are not specified.

For \(a\ne b\), the natural Hardy--Littlewood reconstruction is

\[MT(x,q;a,b)\ \approx\ \mathfrak S(q;a,b) \int_{1}^{x/q} \frac{dt}{\log(qt+a)\log(qt+b)}, \tag{1.1} \]

\[\mathfrak S(q;a,b)= \prod_p \frac{1-\nu_p(q;a,b)/p}{(1-1/p)^2},\qquad \nu_p(q;a,b)= \#\{r\pmod p:(qr+a)(qr+b)\equiv0\pmod p\}. \tag{1.2} \]

This is a reconstruction, not a definition found in the workshop notes. It vanishes when there is a local obstruction. The displayed \(b\)-range includes \(b=a\), where the two forms coincide; that diagonal has a one-prime main term of order \(x/(q\log x)\), not the nondegenerate two-form main term (1.1). A complete version of (W1)--(W2) must therefore separate or explicitly normalize the diagonal.

The final bullet, also verified in the PDF, is:

01592 | AIM-ALGEBRAIC_NUMBER_THEORY-0065

Two Tate lines and the missing adjoint correspondence

P / partially_solved | AIM 研讨会问题汇编

Let F be a real quadratic field, let π be an automorphic form over $\mathbf Q$, and let Π be its base change to F. Then Π contributes a subspace $H^2(\Pi)$ to $H^2(S_F)$ for a Hilbert modular surface S_F for $\mathrm{GL}_2(F)$, while $H^1(\pi)$ occurs in $H^1(M)$ for a modular curve M. As $\operatorname{Gal}(\overline{\mathbf Q}/F)$-modules,

$$ H^2(\Pi)\simeq H^1(\pi)\otimes H^1(\pi). $$

Take two real quadratic fields F_1,F_2, the base changes Π_1,Π_2 of π, and associated Hilbert modular surfaces S_{F_1},S_{F_2}. The summand

$$ H^2(\Pi_1)\otimes H^2(\Pi_2)\subset H^4(S_{F_1}\times S_{F_2}) $$

becomes $H^1(\pi)^{\otimes4}$ over $\operatorname{Gal}(\overline{\mathbf Q}/F_1F_2)$. One therefore expects codimension-two cycles on $S_{F_1}\times S_{F_2}$, defined over F_1F_2. What are they?

Weak approximation for finite quotients with a controlled auxiliary branch point

P / partially_solved | AIM 研讨会问题汇编

Question 35 (recovered). Study weak approximation over \(L\). It was known for a connected linear algebraic group. For a homogeneous space \(G/H\), it was suggested that the same method should work when \(H\) is connected. In particular, decide whether weak approximation holds for \(\mathrm{GL}_n/G\) when \(G\) is a finite subgroup of \(\mathrm{GL}_n\). A further claim attributed to de Jong was that every smooth projective geometrically rationally connected \(L\)-variety satisfies weak approximation, although this was not in the de Jong--Starr paper. Finally, an Enriques surface over \(\mathbb C(t)\) with a rational point but without weak approximation was mentioned.

A cubic homological obstruction for the doubled standard q-tca

P / partially_solved | AIM 研讨会问题汇编

Berenstein--Zwicknagl define quantum analog of \(\operatorname{Sym}(\mathbf S_\lambda)\). For small \(\lambda\), this behaves like the classical case, but for large \(\lambda\) (and \(q\) generic) its isotypic decomposition has smaller multiplicities than the classical case. Are modules over this algebra (as \(q\)-tca's) equivalent to modules in the classical case (as tca's)?

来源字段：http://aimpl.org/repnstability/1/

01667 | AIM-LINEAR_ALGEBRA-0011

A degree-independent ternary rhombus bound and a seven-variable obstruction

P / partially_solved | AIM 研讨会问题汇编

Given positive scalars $a_0, \dots, a_d$ such that \[\frac{a_k^2}{a_{k-1}a_{k+1}}\geq 4 \qquad (0<k<d), \] Hutchinson's theorem says that the generating polynomial $p(x)=\sum_{j=0}^d a_jx^j$ is real-rooted. One can homogenize this to $p(x,y)$.

Now consider the analogue for homogeneous polynomials of three variables. It is known that for each degree $d\geq1$, there exists $\lambda_d>0$ such that if $\lambda\geq\lambda_d$, then the “λ-rhombus log-concavity” of the Maclaurin coefficients of a homogeneous polynomial $p(x,y,z)$ implies that p is real-stable.

Can one remove the dependence of λ_d on d? If yes, then what about for $n>3$ variables?

A genuine-character obstruction and packet test for lifts to covered inner forms

P / partially_solved | AIM 研讨会问题汇编

Is there a natural lifting from representations of G_F to $\widetilde{G'}_F$?

The exact AIM record asks:

The record itself does not define G', the cover, the class of representations, or the sense of “natural.” The immediately preceding AIM problem (3.3) asks for transfer from $\widetilde G_F$ to $\widetilde{G'}_F$ “where two linear groups G_F and G'_F are inner forms each other,” and warns that the centers of the covers may differ. I therefore use the following conservative reconstruction:

* F is a local field (the surrounding base-change problem specifies a characteristic-zero p-adic field); * G and G' are inner forms of a common quasi-split reductive group G^*; * $1\to A\to \widetilde{G'}\to G'(F)\to1$ is a finite central cover, normally of Brylinski--Deligne or étale-metaplectic origin; * a target representation is required to be ϵ-genuine for a fixed injective character $\epsilon:A\hookrightarrow\mathbb C^\times$.

This reconstruction is supported by the neighboring repository records, not by the unavailable web page: on 12 August 2026, `http://aimpl.org/autoformcovergp/3/` returned HTTP 502. No claim below depends on silently adding further structure.

01681 | AIM-REPRESENTATION_THEORY-0113

A normalization audit of the higher-rank Serre weight conjecture

P / partially_solved | AIM 研讨会问题汇编

If σ is any mod-p representation of $\mathrm{GL}_n(\mathbf F_p)$, then there is a Hecke eigenclass $x\in H^d(\Gamma_1(N),\sigma)$, for some d, satisfying $$ T_\ell x=\operatorname{Tr}(\bar\rho(\operatorname{Frob}_\ell))x \quad(\ell\nmid Np), $$ with $p\nmid N$, if and only if $$ N(\bar\rho)\mid N, \qquad \operatorname{JH}(\sigma)\cap \operatorname{Wt}(\bar\rho|_{I_p})\ne\varnothing. $$

Let $$ \bar\rho:G_{\mathbf Q}\longrightarrow \mathrm{GL}_n(\overline{\mathbf F}_p) $$ be continuous and irreducible. The preceding paragraph imposes the higher-rank oddness condition $$ \left|\dim \bar\rho^{c=1}-\dim \bar\rho^{c=-1}\right|\leq 1 $$ for complex conjugation c. Let $N(\bar\rho)$ be its prime-to-p Artin conductor and $$ \Gamma_1(N)=\{g\in \mathrm{SL}_n(\mathbf Z): \text{the bottom row of }g\text{ is }(0,\ldots,0,1)\bmod N\}. $$

The source's **Conjecture 6 (approx.)** is:

It asks whether a specific degree d should occur, expresses the hope $$ \operatorname{Wt}(\bar\rho|_{I_p})\subset \operatorname{Wt}((\bar\rho|_{I_p})^{\mathrm{ss}}), $$ sketches an analogue for a unitary group over an imaginary quadratic field, recalls highest-weight modules and Hodge--Tate numbers $$ a_1+n-1,a_2+n-2,\ldots,a_{n-1}+1,a_n, $$ and gives a tame-inertia/Deligne--Lusztig recipe. The next item in the PDF is Conjecture 7 and is not part of this record.

If $q=p^r$ and $S_r=(p^r-1)/(p-1)$, the displayed map is $$ R(a_1,\ldots,a_n)= (a_n-(n-1)S_r,a_{n-1}-(n-2)S_r,\ldots,a_2-S_r,a_1) \pmod{q-1}. $$ Also, the niveau-s characters in the tame recipe are $\chi,\chi^p,\ldots,\chi^{p^{s-1}}$, not the malformed OCR exponents.

01690 | AIM-LINEAR_ALGEBRA-0012

A Schur-positive order-two case for affine elementary-symmetric Toeplitz matrices

P / partially_solved | AIM 研讨会问题汇编

There are many classical theorems about operations that preserve negative-real-rootedness of polynomials: for instance, \(d/dx+a\) or \(x\,d/dx+a\) with \(a\geq 0\); or Hadamard product; or Hadamard product with an extra \(n!\) (sometimes known as Schur composition); or Brändén's (2011) log-concavity operation. These can be reinterpreted as statements about *pointwise* total positivity for certain Toeplitz matrices involving elementary symmetric functions (e.g. \((n+a)e_n\)). Can these results be upgraded to total positivity in the *monomial* basis? Computational tests suggest that the answer is yes. But we have been unable, thus far, to come up with a plausible strategy for proving any of these conjectures.

来源字段：http://aimpl.org/totalpos/1/

01691 | AIM-REPRESENTATION_THEORY-0070

A sector-and-twist test for covering-group ABV

P / partially_solved | AIM 研讨会问题汇编

ABV for covering groups. There is a canonical isomorphism as K-groups $$ KRep\,\widetilde G_{\mathbb R}\cong\bigl(KPer_H(X)\bigr)^*, $$ where X is a $\mathbb C$-algebraic variety and H is a $\mathbb C$-algebraic group (for the trivial cover, $H={}^\vee G$).

The exact AIM record (2013 workshop *Automorphic forms and harmonic analysis on covering groups*, “Fundamental properties,” Conjecture 2.3) is:

The original AIMPL URL returned a 502 error when checked on 12 August 2026. The formula is a compressed version of the Adams--Barbasch--Vogan (ABV) perfect pairing: $KRep$ is a Grothendieck group of finite-length representations, $KPer$ is a Grothendieck group of equivariant perverse sheaves on a geometric parameter space, and * is an algebraic dual.

Two qualifications suppressed in the AIM slogan are mathematically essential.

1. ABV works most cleanly after fixing an infinitesimal character, and its global notation includes strong real forms and canonical projective representations. A finite regular block is the right test object. 2. If $1\to A\to\widetilde G_{\mathbb R}\to G(\mathbb R)\to1$ is a finite central cover, “genuine” means that a specified character $\epsilon:A\to\mathbb C^\times$ acts on every representation. Modern covering-group L-groups also depend on this ϵ.

Accordingly, the recovered target is a blockwise, fixed-ϵ pairing

$$ K_0\bigl(\mathcal B_\epsilon(\widetilde G_{\mathbb R})\bigr) \simeq K_0\bigl(\operatorname{Per}_{H_\epsilon}(X_{\epsilon,\mathcal O},\beta_\epsilon)\bigr)^*, \tag{1.1} $$

where a possible twist β_ϵ may instead be absorbed into the definitions of H_ϵ and $X_{\epsilon,\mathcal O}$. This is a reconstruction, not a claim that these objects have been constructed in general.

来源字段：http://aimpl.org/autoformcovergp/2/

01692 | AIM-LINEAR_ALGEBRA-0017

A sharp codimension-one compound threshold

P / partially_solved | AIM 研讨会问题汇编

In the strict convention used below, \(TP_r\) means that every minor of order at most \(r\) is positive, and \(TP\) means that every minor is positive.

The record begins with the dimension-free Katkova--Vishnyakova phenomenon: a positive square matrix satisfying \[ad-\lambda bc>0,\qquad \lambda\geq4, \] on its \(2\times2\) submatrices is TP. It asks for higher-order quantitative conditions that upgrade \(TP_{k-1}\) to TP and for optimal constants.

There is an important formulation distinction. The AIM problem literally says “every \(2\times2\) submatrix,” which ordinarily means every choice of two rows and two columns. The primary theorem of Katkova--Vishnyakova needs only the **local adjacent-entry** inequalities \[a_{ij}a_{i+1,j+1}>c\,a_{i,j+1}a_{i+1,j}. \tag{1.1} \] Thus the literal AIM hypothesis is stronger.

A stabilized-center criterion for distributions

P / partially_solved | AIM 研讨会问题汇编

Is there a geometric description of the center of \(\mathrm{Rep}_0G\)? Possibly related to affine Springer fibers?

If one had a geometric description of the categorical center of the principal block \(\mathrm{Rep}_0(G)\), would it describe the algebraic center \(Z(\operatorname{Dist}(G))\) of the distribution algebra?

The pronoun “this” is not meaningful in isolation.

Thus the conservative reconstruction of 6.2 is:

This is a reconstruction from the adjacent record, not a claim that the proposed geometric description in 6.1 exists. The AIM page is terse and specifies neither the ground field nor hypotheses on \(G\). In this report, \(k\) is algebraically closed of characteristic \(p>0\), and \(G\) is a smooth connected affine algebraic group; reductivity is needed only when discussing the workshop's geometric context.

01695 | AIM-REPRESENTATION_THEORY-0082

A trace-and-type normalization ledger for formal degrees

P / partially_solved | AIM 研讨会问题汇编

Interpret formal degrees of representations of $\widetilde{G}_{F}$ on level of Hecke algebra. ($\grave{\mathrm a}$ la Opdam, Reeder, et al.)

Here $\widetilde G_F$ is read as the group of F-points of a covering group. The broader workshop summary makes the motivating example more precise: the Bernstein blocks containing the even and odd Weil representations of the two-fold metaplectic group should be compared with Iwahori-spherical blocks of equal-rank odd orthogonal groups. The summary singles out preservation of the natural L^2 norm under the Hecke-algebra isomorphism, because that is exactly what transports Plancherel measure and hence formal degrees.

Thus the problem has two levels:

1. identify formal degree intrinsically on a Hecke algebra equipped with its positive trace; and 2. keep track of the normalization needed to recover the group formal degree from the type Hecke algebra.

Algebraic Stories - Ideals of generic forms

P / partially_solved | AMR 问题清单汇编

[Fr\"oberg's Conjecture, 1985] Let $f_1, \dots, f_r$ be generic forms of degrees $d_1, \dots, d_r$, respectively. Then the Hilbert series of the quotient algebra $R = S/(f_1,\ldots,f_r)$ is given by $$ \operatorname{Hilb}_R(t)=\left[\frac{\prod_{i=1}^r(1-t^{d_i})}{(1-t)^n}\right]_+. $$ Here $[\sum_{i\ge0}a_iz^i]_+:=\sum_{i\ge0}b_iz^i$, with $b_i=a_i$ if $a_j\ge0$ for all $j\le i$ and $b_i=0$. In other words, $[\sum_{i\ge0}a_iz^i]_+$ is the truncation of a power series at its first non-positive coefficient.

01747 | AIM-REPRESENTATION_THEORY-0088

An elementary-generator characterization of the André-Yan theory

P / partially_solved | AIM 研讨会问题汇编

Characterize the André-Yan theory of \(U_n(q)\) intrinsically in terms of its elementary, single-box irreducible characters, and determine whether it is the coarsest supercharacter theory in which those characters remain individual supercharacters.

The original PDF was checked directly. It gives the same wording (with André printed without the accent) and no additional remark.

The dependence on the preceding item is essential. Problem 1.3 reads:

The following Problem 1.6 also records the key structural fact that, for \(U_n\), every supercharacter is a product of supercharacters that happen to be irreducible. Thus the most literal precise reconstruction of Problem 1.4 is:

This report proves such a characterization. Since the source request is open-ended and never defines what class of “characterizations” is intended, the result is conservatively classified as a rigorous partial result rather than as an unconditional full solution to every possible reading.

The list came from the AIM workshop *Supercharacters and combinatorial Hopf algebras*, held May 17-21, 2010.

来源字段：https://aimath.org/WWN/supercharacters/supercharacters.pdf

01748 | AIM-LINEAR_ALGEBRA-0014

An independent-cycle obstruction to Pólya frequency

S / solved | AIM 研讨会问题汇编

The record is Problem 1.5 in the AIM workshop list *Theory and applications of total positivity* and is attributed there to Pavlo Pylyavskyy. The source display is a nested sum: for each \(k\), its inner sum contributes one copy of \(z^k\) for every matching with \(f(\mu')=k\). Equivalently,

\[F_{G,\mu}(z):=\sum_{\substack{\mu'\text{ perfect}\\ \mu'\ne\mu}} z^{f(\mu')}=\sum_{k\geq0}a_kz^k, \qquad a_k=\#\{\mu'\ne\mu:f(\mu')=k\}. \]

Here \(f(\mu')\) is the number of noncontractible cycles obtained by superimposing \(\mu\) and \(\mu'\). Equivalently, one may discard the doubled common edges and use the alternating cycles of \(\mu\mathbin\triangle\mu'\); doubled common edges are contractible and do not affect \(f\).

The questions are whether \((a_k)\) is always a Pólya-frequency (PF) sequence and, after putting indeterminate weights on the edges, whether the associated infinite triangular Toeplitz matrix is coefficientwise totally nonnegative (TN). The source notes that coefficientwise \(\mathrm{TN}_2\) is known.

An obstruction to double-covering FI and a framed spin-FI supercategory

P / partially_solved | AIM 研讨会问题汇编

FI like categories. Modify FI to use double cover of symmetric groups.

The exact AIM record, from the workshop *Representation stability*, section "Representation theory," problem 3.4, is:

We therefore distinguish three plausible readings.

1. Construct a category over FI whose automorphism group at $[n]$ is a Schur double cover \(1\to\{1,z\}\to\widehat S_n\to S_n\to1\), and whose every Hom-set is a two-sheeted lift of the corresponding FI Hom-set. 2. Construct a linear category whose endomorphism algebras are the genuine spin quotients \(k[\widehat S_n]/(z+1)\), so its modules are sequences of genuine spin representations. 3. Use the Sergeev/Hecke--Clifford superalgebras, which are super-Morita equivalent to spin symmetric-group algebras, and formulate stability in the super setting.

The first reading is the most literal but is impossible. The obstruction is already visible on the map from the empty set. We prove it below. We then give a coherent correction for readings (2)--(3): retain an ordered frame of the complement of an injection, lift those framed morphisms to compatible Schur covers, and pass to the genuine superlinear sector. The correction has explicit composition, stabilizers, free modules, and a classification of its modules as compatible sequences.

01813 | AIM-REPRESENTATION_THEORY-0028

Central stability of the standard VIC module and the complement-orbit correction

P / partially_solved | AIM 研讨会问题汇编

It starts over a field \(\mathbf k\) with

\[\mathrm{PBC}_{p}^{n} =\{(v_1,\ldots,v_p,C):v_i\text{ are linearly independent and } C\text{ complements their span}\}. \]

It says that these sets form a semisimplicial \(\mathbf{VIC}(\mathbf k)\)-set, that the resulting space is \((n-3)/2\)-connected, and that the augmented chain complex

\[\mathbb Z[\mathrm{PBC}_\bullet]\longrightarrow\mathbb Z\longrightarrow0 \]

is “acyclic (exact).” It describes a face as removing one vector and adding that vector to the complement. It then claims the same over a general ring \(R\), including the identification

\[\mathbb Z[\mathrm{PBC}_p] =\mathbb Z[\mathrm{GL}_n(R)] \otimes_{\mathbb Z[\mathrm{GL}_{n-(p+1)}(R)]}\mathbb Z, \]

and asks whether

\[R[\mathrm{GL}_n(R)]\otimes_{R[\mathrm{GL}_{n-(\bullet+1)}(R)]} R^{n-(\bullet+1)}\longrightarrow R^n\longrightarrow0 \tag{1} \]

is highly acyclic. The record says that an affirmative answer for \(R=\mathbb Z\) would imply that \(H_2(\mathrm{IA}_n)\) is presented in finite degree.

The display requires five repairs.

1. **Semisimplicial indexing.** A \(p\)-simplex has \(p+1\) vectors, conventionally written \((v_0,\ldots,v_p,C)\). The exponent \(n-(p+1)\) in (1) confirms this convention. The source definition with only \(p\) vectors is shifted. 2. **Connectivity is not total exactness.** An \(r\)-connected realization has vanishing reduced homology only through degree \(r\). It need not have an exact augmented chain complex in every degree. A concrete counterexample appears in Theorem C below. 3. **Ring versus coefficient ring.** The same symbol \(R\) is being used for the ring defining \(\mathrm{GL}_n(R)\) and for chain coefficients. This is legitimate for a commutative ring, but it must be stated; over a noncommutative ring one must also fix left/right conventions. 4. **The denominator needs a block embedding.** We use \(\mathrm{GL}_{n-p-1}(R)\hookrightarrow\mathrm{GL}_n(R)\) acting on the standard complement and fixing the last \(p+1\) standard vectors. There is no omitted unipotent group when the complement itself is distinguished: preserving it kills the off-diagonal block. 5. **General rings have an orbit problem.** If “complement” permits a nonfree stably free summand, the \(\mathrm{GL}_n(R)\)-action is not transitive and the single induced module in the source sees only the free-complement orbit. Theorem B gives the correct orbit decomposition and an explicit example.

With these repairs, (1) is exactly the central stability complex of the standard \(\mathrm{VIC}(R)\)-module \(A_n=R^n\).

01820 | AIM-REPRESENTATION_THEORY-0001

Characterwise Jochnowitz congruences via an integral class-group comparison

P / partially_solved | AIM 研讨会问题汇编

Let f be a modular form of weight 2 and let χ be a character of the class group of an imaginary quadratic number field K. Formulate a direct connection \[L'(f\otimes\theta_\chi,\tfrac12) \longleftrightarrow L(g\otimes\theta_\chi,\tfrac12), \] for a modular form g on a definite quaternion algebra with some congruence to f.

The AIM record (workshop *Analytic, arithmetic, and geometric aspects of automorphic forms*, Group Problems 1.1) asks:

Two clarifications are essential.

1. The displayed center $s=1/2$ is the unitary automorphic normalization. For a weight-2 classical newform, \[L_{\mathrm u}(s,\pi_f\times\operatorname{AI}_K^{\mathbf Q}\chi) =L_{\mathrm{cl}}(s+\tfrac12,f/K,\chi). \] Thus the same center is $s=1$ in the classical notation used by Bertolini--Darmon and Vigni. 2. A weight-2 form on a definite quaternion algebra is an algebraic automorphic form on a finite double-coset set. Its Jacquet--Langlands transfer is the corresponding classical GL_2 newform. The definite form itself does not have a holomorphic q-expansion.

Here $\operatorname{AI}_K^{\mathbf Q}\chi$ is represented by the weight-1 theta series θ_χ when the induction is cuspidal. For exceptional characters for which the induction decomposes, the equivalent base-change L-function formulation remains the unambiguous one.

Cohomological tools for pseudorepresentations and a two-character visibility-order lemma

P / partially_solved | AIM 研讨会问题汇编

Problem 3. Classically, if one is looking at deformation rings of Galois representations one has various cohomological tools. One would like analogues of these in the situation of pseudo-representations.

This is a request for a tangent-and-obstruction theory, not a yes/no conjecture. In the PDF the next line is the heading “9.

The immediate source context matters. Sections 8.1-8.2 discuss two-dimensional pseudocharacters, their characteristic polynomials and Cayley-Hamilton identities, the relation between representation and pseudorepresentation moduli, the absolutely irreducible theorem of Nyssen-Rouquier, and the geometry near a sum of two distinct characters. Thus “cohomological tools” naturally means at least:

1. a description of first-order pseudodeformations; 2. obstruction classes for lifting through small extensions; 3. a way to impose local or global deformation conditions; and 4. a replacement, in the reducible case, for the usual \(H^1(G,\operatorname{ad}\bar\rho)\) and \(H^2(G,\operatorname{ad}\bar\rho)\).

Color-shear Ext classes and the annulus filtration correction

P / partially_solved | AIM 研讨会问题汇编

It asks for naturally occurring nontrivial FI_2-modules. For a manifold X with two specified boundary components it claims that

$$ V_n=H_i(\operatorname{PConf}^n(X)) $$

has an FI_2-module structure. For the cylinder $X=S^1\times I$ and $i=1$, it records

$$ 0\longrightarrow \widetilde M(1)\longrightarrow V \longrightarrow\widetilde M(2)\longrightarrow0, $$

where the tildes mean pullback from FI, says that V has an ordinary FI-structure but is not such a pullback, and asks:

1. what generally happens for $H_i(\operatorname{PConf}(X))$; and 2. whether $\operatorname{Ext}(M,N)$ can be calculated in FI_2-modules.

The literature note attributes to Andrew Snowden the observation that Koszul resolutions calculate these Ext groups and cites Church--Ellenberg--Farb [CEF].

Two corrections are necessary before doing mathematics.

Notation correction. CEF define $M(a)=k[\operatorname{Inj}([a],-)]$, the free module generated by the regular S_a-representation, and more generally $M(W)$. Literal $M(2)$ has dimension $n(n-1)$. But

$$ \operatorname{rank}H_1(\operatorname{PConf}_n(S^1\times I)) =n+\binom n2. $$

Thus the cylinder statement can only use the module induced from the trivial S_2-representation, of dimension $\binom n2$. We denote this unambiguously by

$$ M_{(2)}(S)=k\binom S2, \qquad M_{(1)}(S)=kS. $$

Presumably the partition (2), or its Young diagram, was flattened in the source.

Filtration correction. Under the standard homology stabilization by inserting points at boundary collars, pair-collision meridians are preserved. They therefore form the $M_{(2)}$ submodule.

$$ \boxed{0\longrightarrow\widetilde M_{(2)}\longrightarrow H_1 \longrightarrow\widetilde M_{(1)}\longrightarrow0,} $$

the reverse of the recorded display. This is proved in §7. If a different variance or dual convention was intended, it must be stated; it is not the covariant homology stabilization in the record.

Here $\operatorname{PConf}_n(X)$ means ordered configurations of n distinct interior points. Replacing the compact cylinder by its interior does not change the homotopy calculation and identifies it with $\mathbf C^*$.

Component extraction in completed-cohomology factorizations

P / partially_solved | AIM 研讨会问题汇编

The document itself warns that it was typeset during the talks and may contain transcription errors.

Let \(\mathbb F\) be a finite field, let \(\mathcal O=\mathcal O_K\) be a complete discrete valuation ring with residue field \(\mathbb F\), and let \[\bar\rho:G_{\mathbb Q}\longrightarrow \mathrm{GL}_2(\mathbb F) \] be absolutely irreducible and modular. Let \(R\) be its universal deformation ring for deformations unramified outside a finite set \(\Sigma\), and let \(R^{\mathrm{mod}}\) be the image of \(R\) in the localized Hecke algebra. The notes describe \(\operatorname{Spec}R^{\mathrm{mod}}\) as the Zariski closure of the classical modular points. Put \[\widehat H^1=\widehat H^1_{\Sigma,\bar\rho}, \] the localized completed cohomology of modular curves, and let \(I\) define a component of \(R^{\mathrm{mod}}\).

After restoring notation from the primary PDF, Conjecture 4 asks for an equivariant isomorphism \[\tag{3} \widehat H^1[I]\stackrel{??}{\cong} \rho_{R^{\mathrm{mod}}/I} \widehat\otimes_{R^{\mathrm{mod}}/I} \widehat\pi_p\!\left(\rho_{R^{\mathrm{mod}}/I}|_{G_{\mathbb Q_p}}\right) \widehat\otimes \left(\widehat\bigotimes_{\substack{\ell\ne p\\ \ell\in\Sigma}} \widehat\pi^{\mathrm{mod}}_\ell\!\left(\rho_{R^{\mathrm{mod}}/I}|_{G_{\mathbb Q_\ell}}\right) \right). The factors carry, respectively, the actions of \(G_{\mathbb Q}\), \(\mathrm{GL}_2(\mathbb Q_p)\), and \(\mathrm{GL}_2(\mathbb Q_\ell)\). The source calls the \(p\)-adic factor an orthonormalizable \(R^{\mathrm{mod}}/I\)-Banach module supplied by \(p\)-adic local Langlands and calls the factors away from \(p\) the \(\mathfrak m\)-adic completions of modified local Langlands in families.

The notes impose: (1) a scalar-endomorphism/genericity condition on the residual restriction at \(p\), excluding in particular a twist of \(\left(\begin{smallmatrix}\omega^{-1}&*\\0&1\end{smallmatrix}\right)\); and (2) existence and classical-point interpolation of \(\widehat\pi_p\). The punctuation in (1) is defective: the most coherent reading is “irreducible, or a nonsplit extension \(\left(\begin{smallmatrix}\chi&*\\0&\psi\end{smallmatrix}\right)\) with \(\chi\ne\psi\),” together with the stated exceptional exclusion. Under these two hypotheses, Theorem 14 in the same source states that (3) holds.

The first source remark includes Corollary 15, which gives classicality for potentially semistable trianguline specializations with distinct Hodge--Tate weights and finite-slope overconvergent modularity for trianguline specializations. The genuine second remark ends with anticipated Fontaine--Mazur, eigencurve \(p\)-adic \(L\)-function, and mod-\(p\) consequences. Schien” belongs to the next section and is unrelated boundary contamination.

01881 | AIM-LINEAR_ALGEBRA-0001

Convention audit and connected linear-multiplicity obstructions

P / partially_solved | AIM 研讨会问题汇编

Let G be a graph with maximum degree bounded by Δ. For the following choices of Hermitian matrix M_G associated with G, what is the maximum multiplicity of the second largest eigenvalue of M_G?

The four choices are (1) the adjacency matrix, (2) the Laplacian matrix, (3) a Schrödinger operator $D+A_G$ with arbitrary diagonal D, and (4) a Hermitian weighted adjacency matrix satisfying $M_G[i,j]=0$ whenever $\{i,j\}\notin E(G)$.

1. The order $n=|V(G)|$ and connectedness are not stated in the first sentence. The cited adjacency literature formulates the intended problem for connected n-vertex graphs, with Δ fixed and $n\to\infty$. 2. For the cited adjacency problem, eigenvalues are listed with multiplicity, $$\lambda_1\geq \lambda_2\geq\cdots\geq\lambda_n,$$ and the multiplicity of λ_2 means the multiplicity of its numerical value. For a connected unweighted graph Perron--Frobenius makes λ_1 simple, so this agrees with the second *distinct* eigenvalue. That equivalence fails for the other matrix classes.

This report keeps the ordered-with-multiplicity convention used by Haiman--Schildkraut--Zhang--Zhao and treats “second-largest” literally. Results for a second-distinct convention are called out separately. “Laplacian” means the combinatorial Laplacian $L=\operatorname{diag}(d)-A$, and “second” means second-largest as written in the prompt, not the usual second-smallest algebraic-connectivity eigenvalue.

Coordinate Realization of Characteristic-Polyhedron Multiplicity

O / open | Oberwolfach 报告问题汇编

Let R be an excellent regular local ring with regular parameters (u,y), and let $f\in R\setminus\langle u\rangle$. Write $m=m(f)$ and let $\operatorname{in}_0(f)\in k[Y_1,\ldots,Y_r]$ be its degree-m initial form. Assume there is no proper k-subspace $T\subset k[Y_1,\ldots,Y_r]_1$ with $\operatorname{in}_0(f)\in k[T]$. If $\widehat y_j=y_j+\varphi_j$, with $\varphi_j\in\langle u\rangle\widehat R$, and $f\in\langle\widehat y\rangle^m$, do elements $z_1,\ldots,z_r\in R$ exist such that (u,z) is a regular system of parameters,

$$\langle z\rangle\widehat R=\langle\widehat y\rangle,$$

and $f\in\langle z\rangle^m$?

01890 | AIM-REPRESENTATION_THEORY-0024

Cyclotomic bounds and even-dimensional transfer for stable multiplicities

P / partially_solved | AIM 研讨会问题汇编

The AIM record is Problem 2.1, “Quasi-polynomial behavior,” in the Topology section of the Representation Stability workshop list. Its first example concerns

\[V(1,1)_n=\bigwedge^2\mathbb Q^{n-1}\cong S^{(n-2,1,1)} \]

and the multiplicity of this stable irreducible in \(H^i(\operatorname{PConf}_n(\mathbb C);\mathbb Q)\). The displayed stable answer is

\[d_i(1,1)= \begin{cases} 2i-2,&i\equiv0\pmod4,\\ 2i-3,&i\equiv1\pmod4,\\ 2i-2,&i\equiv2\pmod4,\\ 2i-1,&i\equiv3\pmod4, \end{cases} \qquad (i\ge2). \]

The record then says that, for fixed \(\lambda\), the stable multiplicity is quasi-polynomial in \(i\), and asks:

1. For which manifolds \(X\) does analogous behavior hold?
2. What additional hypothesis on a finitely generated FI-algebra forces analogous behavior?

- Both inner products in the source are missing the closing delimiter before the subscript \(S_n\). They are read as \(\langle H^i(\operatorname{PConf}_n(X);\mathbb Q),V(\lambda)_n\rangle_{S_n}\). - The source calls the first number \(a_n\), although after stabilization it is a function of \(i\). We write \[d_i^X(\lambda)=\lim_{n\to\infty} \left\langle H^i(\operatorname{PConf}_n(X);\mathbb Q),V(\lambda)_n\right\rangle_{S_n}. \] - For a partition \(\lambda\), \(V(\lambda)_n\) means the irreducible \(S_n\)-representation \(S^{(n-|\lambda|,\lambda)}\), defined once \(n-|\lambda|\ge\lambda_1\). - The order of operations is essential: fix \(i\), stabilize in \(n\), and only then study the resulting sequence as \(i\) varies. No simultaneous two-variable limit is asserted. - The FI-algebra question suppresses the grading. Without graded pieces there is no variable \(i\). We interpret it as asking about \(\lim_n\langle A_n^i,V(\lambda)_n\rangle_{S_n}\) for a cohomologically graded FI-algebra \(A^\bullet\).

The original AIM URL did not return usable content in the literature check. The reconstruction above is independently confirmed by Chen’s notation, transfer identity, stable generating function, and the exact \(V(1,1)\) example. Chen’s coefficient table also confirms that the displayed four-case formula begins at \(i=2\).

Elementary characters generate Andre's supercharacter theory

S / solved | AIM 研讨会问题汇编

Problem 1.3.

In the original supercharacter theory of Andre, the supercharacters/superclasses associated to single boxes above the identity are irreducible. Is Andre's supercharacter theory the coarsest containing this?. If not, what is the coarsest supercharacter theory containing the irreducibles?

A supercharacter theory \(\mathsf T\) contains the elementary irreducibles if each elementary irreducible character is a singleton block of the character partition of \(\mathsf T\).

Elementary symmetric of a sum of matrices

P / partially_solved | Open Problem Garden

Problem

Given a Matrix A, the k-th elementary symmetric function of A, namely $S_k(A)$, is defined as the sum of all k-by- k principal minors.

Find a closed expression for the k-th elementary symmetric function of a sum of N n-by- n matrices, with $0\le N\le k\le n$ by using partitions.

Emerton's mod-p local-global factorization and a finite-level one-prime ratio law

P / partially_solved | AIM 研讨会问题汇编

The record is Conjecture 3 in Michael Volpato's notes from the 2006 AIM workshop *(p)-adic representations, modularity, and beyond*, followed by questions of Calegari and Diamond. The PDF warns that the notes may contain transcription errors.

Let \[\bar\rho:G_{\mathbb Q}\longrightarrow \mathrm{GL}_2(\overline{\mathbb F}_p) \] be absolutely irreducible and odd, and let \(\mathfrak m_N\) be the maximal ideal of the level- \(N\) Hecke algebra determined away from \(N\) by \(T_\ell-\operatorname{tr}\bar\rho(\operatorname{Frob}_\ell)\). Then Emerton predicted an isomorphism of \(G_{\mathbb Q}\times\mathrm{GL}_2(\mathbb A_f)\)-representations of the form \[\varinjlim_N H^1\!\left(X(N)_{\overline{\mathbb Q}}, \overline{\mathbb F}_p\right)[\mathfrak m] \;\cong\; \left(\bigotimes_\ell'\pi^{\mathrm{modified}}_\ell (\bar\rho|_{G_{\mathbb Q_\ell}})\right)\otimes\bar\rho. \tag{1} \] Each local factor is to be a finite-length admissible smooth representation of \(\mathrm{GL}_2(\mathbb Q_\ell)\). The later formulation in Emerton's paper uses etale cohomology of the full, geometrically disconnected modular curve \(Y(N)\), a finite coefficient field \(k\), and the Galois multiplicity space \(\operatorname{Hom}_{k[G_{\mathbb Q}]}(\bar\rho,H^1_k)\). That formulation is safer in characteristic \(p\), where an isotypic summand need not be semisimple.

Calegari then asks for explicit finite-level multiplicities, noting that the factors away from \(p\) should be easy and that the factor at \(p\) was a thesis-sized problem. Diamond asks for reducible residual representations and for an analogue on Shimura curves attached to quaternion algebras unramified at \(p\).

01951 | AIM-LINEAR_ALGEBRA-0015

Exact block witnesses for the Barrett-Johnson converse

S / solved | AIM 研讨会问题汇编

If \(F_\lambda(A)\geq F_\mu(A)\) for every \(n\times n\) totally nonnegative matrix \(A\), must \(\lambda\preceq\mu\)?

This is Problem 1.55 in the AIM list from the workshop *Theory and applications of total positivity*. Its literature field says, “This has now been answered affirmatively.”

The official AIM workshop report and the published solution identify the intended reading: the sums are **over all ordered set partitions** of the specified types. The listed AIM Problem Lists URL returned HTTP 502 during this attempt, so it was not used to resolve the ambiguity.

For a partition \(\alpha=(\alpha_1,\ldots,\alpha_t)\vdash n\), let \(\mathcal P(\alpha)\) be the set of ordered tuples \((I_1,\ldots,I_t)\) of pairwise disjoint subsets whose union is \([n]\) and for which \(|I_k|=\alpha_k\). Define \[S_\alpha(A)=\sum_{(I_1,\ldots,I_t)\in\mathcal P(\alpha)}\prod_{k=1}^t\det A_{I_k,I_k}, \qquad F_\alpha(A)=\left(\prod_{k=1}^t\alpha_k!\right)S_\alpha(A). \] The empty determinant convention is \(\det A_{\varnothing,\varnothing}=1\) if trailing zero parts are used.

For partitions \(\lambda,\mu\vdash n\), write \[\lambda\preceq\mu \quad\Longleftrightarrow\quad \sum_{i=1}^k\lambda_i\leq\sum_{i=1}^k\mu_i \quad\text{for every }k\geq1, \] after padding with zeros. Thus “\(\mu\) majorizes \(\lambda\)” means \(\lambda\preceq\mu\). The precise question is:

The source takes the same number of positive parts for the two partitions. The published result allows different lengths, and hence strictly contains the source formulation.

The factorials are exactly the normalization for an average. Since \(|\mathcal P(\alpha)|=n!/(\alpha_1!\cdots\alpha_t!)\), \[F_\alpha(A)=n!\,\frac{1}{|\mathcal P(\alpha)|}\sum_{I\in\mathcal P(\alpha)}\prod_k\det A_{I_k,I_k}. \]

Fixed second adjacency eigenvalue multiplicity: formulation audit and exact boundary cases

P / partially_solved | AIM 研讨会问题汇编

For a fixed choice of parameters ρ and Δ, what is the largest possible multiplicity of the second eigenvalue of the adjacency matrix A_G with the constraint that $\lambda_2(A_G) = \rho$.

“Let G be a graph with maximum degree bounded by Δ.”

The surrounding working-group heading is “Multiplicity of λ_2 for Cayley graphs of bounded degree,” but item (1) and item (2) themselves say “graph,” and the report separately says that the group investigated Cayley graphs. Thus restricting the formal question to Cayley graphs would be an additional assumption, not a safe source reconstruction.

Several quantifiers remain implicit even in the PDF:

- The graph is naturally read as a finite, undirected, simple graph, as in the cited adjacency-spectrum literature, but the PDF does not say this in item (2). - Connectedness is essential and is not stated. The cited theorem of Jiang-Tidor-Yao-Zhang-Zhao and the later papers formulating this fixed-eigenvalue question use connected graphs. - No order $n=|V(G)|$ appears. This may be deliberate: fixing ρ and Δ suggests asking for a uniform bound over all orders. If that supremum is infinite, an order-dependent extremal function is the useful replacement. - The literature orders adjacency eigenvalues with multiplicity, \[\lambda_1(G)\ge \lambda_2(G)\ge\cdots\ge\lambda_n(G). \] “Second distinct eigenvalue” is a different convention. For connected graphs the Perron root is simple, so the value λ_2 is also the second distinct value. For disconnected graphs the conventions can differ. - A maximum-degree bound is integral. If the source parameter Δ is real, replace it by $D=\lfloor\Delta\rfloor$.

Three readings must therefore be separated.

1. **Canonical sentence literally:** Δ never constrains G. 2. **PDF-context reading:** G has maximum degree at most D, but need not be connected. 3. **Repaired connected reading:** G is a finite connected simple graph of maximum degree at most D, and eigenvalues are ordered with multiplicity.

For the repaired reading define

\[F_{\mathrm{conn}}(\rho,D) =\sup_G m_G(\rho), \]

where the supremum runs over all finite connected simple graphs with $\Delta(G)\le D$ and $\lambda_2(G)=\rho$, and $m_G(\rho)=\dim\ker(A_G-\rho I)$. An empty admissible family is called **infeasible**, not assigned the misleading value zero. The order-specific repair is

\[M_{\mathrm{conn}}(n;\rho,D) =\max_{\substack{|V(G)|=n,\ G\ {\rm connected,\ simple}\\ \Delta(G)\le D,\ \lambda_2(G)=\rho}}m_G(\rho), \]

with the understanding that some orders have no admissible graph.

Herzig's semisimple weight recipe and extension sensitivity

P / partially_solved | AIM 研讨会问题汇编

The document warns that it was typeset during the talks and may contain transcription errors.

The immediately preceding discussion is essential. For $q=p$, write the semisimplified inertial representation as $$\tau:=\rho|_{I_p}^{\mathrm{ss}} =\bigoplus_i\left(\chi_i\oplus\chi_i^p\oplus\cdots \oplus\chi_i^{p^{s_i-1}}\right), \qquad \sum_i s_i=n, $$ where χ_i has minimal niveau s_i and factors through $\mathbb F_{p^{s_i}}^\times$. This determines a maximal torus $$ T=\prod_i\mathbb F_{p^{s_i}}^\times\subset\mathrm{GL}_n(\mathbb F_p) $$ and a Teichmüller lift $\widetilde\chi$ of the product character. The notes attach a characteristic-zero representation $$ V(\tau)\overset{\mathrm{def}}=V(T,\widetilde\chi) $$ of $\mathrm{GL}_n(\mathbb F_p)$, described there as induction from a product of cuspidal representations. In Herzig’s later formalization this is the genuine Deligne--Lusztig representation attached to the corresponding maximally split dual pair.

For a Serre weight $F(a_1,\ldots,a_n)$, the reflection/regularization operator in the $q=p$ case is $$ R\bigl(F(a_1,\ldots,a_n)\bigr) =F(a_n-(n-1),a_{n-1}-(n-2),\ldots,a_2-1,a_1)_{\mathrm{reg}}. $$ The subscript means the regular Serre weight corresponding to the resulting class modulo $p-1$. On regular weights, $$ R^2(F)=F\otimes\det^{\,1-n}. $$ The workshop puts quotation marks around “map” and says that it does not always associate a regular weight; this records a genuine 2006 ambiguity at irregular boundaries and for the contemplated $q=p^r$ extension. The single-valued $q=p$ formula above and the later multivalued $n=2,q=p^r$ extension are taken from Herzig’s precise 2009 formulation, not silently attributed to the rough notes.

With this context, the exact recovered conjecture is $$ \tag{C7} \operatorname{Wt}\!\left(\rho|_{I_p}^{\mathrm{ss}}\right)_{\mathrm{reg}} =R\!\left(\operatorname{JH}\!\left(\overline{V\!\left(\rho|_{I_p}^{\mathrm{ss}}\right)} \right)\right). $$ Here the overline is the reduction modulo p of a stable lattice, and JH is the set of Jordan--Hölder constituents, with multiplicities forgotten. The PDF prints “Conjecture 7 (Herzig(?)).”

The two examples following (C7) say:

- for $n=3,q=p$, R can be extended as a one-to-many map and yields all predicted weights; - for $n=2,q=p^r$, such an extension agrees with “Fred’s conjecture” (Fred Diamond’s part in the emerging Buzzard--Diamond--Jarvis recipe), although the notes say that several extensions were then possible.

The global eigenclass and cohomological-degree assertions in Conjectures 5 and 6 are not taken over here.

02115 | AMR-124-0001

Iwahori-Hecke Algebras - Problem 1

O / open | AMR 问题清单汇编

Let I be a finite set and let $(m_{ij})_{(i,j)\in I\times I}$ be a symmetric matrix whose diagonal entries are 1 and whose nondiagonal entries are integers ≥2 or ∞. Let W be the group with generators $\{s_i;i\in I\}$ and relations $(s_is_j)^{m_{ij}}=1$ for any i,j such that $m_{ij}<\infty$; this is a Coxeter group. (Examples of Coxeter groups are the Weyl groups of simple Lie algebras; these are finite groups. Other examples are the affine Weyl groups which are almost finite.) For $w\in W$ let $|w|$ be the smallest integer $n\ge0$ such that w is a product of n generators $s_i,i\in I$. We assume that we are given a weight function $L:W@>>>\mathbb{N}$ that is, a function such that $L(w)>0$ for all $w\in W-\{1\}$ and $L(ww')=L(w)+L(w')$ for any w,w' in W such that $|ww'|=|w|+|w'|$. (For example, $w\mapsto|w|$ is a weight function.) Let $A=\mathbb{Z}[v,v -]$ where v is an indeterminate. Let H be the free A-module with basis $\{T_w;w\in W\}$. There is a unique structure of associative A-algebra on H for which $(T_{s_i}+v^{-L(s_i)})(T_{s_i}-v^{L(s_i)})=0$ for $i\in I$ and $T_wT_{w'}=T_{ww'}$ for any w,w' in W such that $|ww'|=|w|+|w'|$; this is the Iwahori-Hecke algebra associated to W,L.

For $c\in\mathbb{C}-\{0\}$ let $H_c=\mathbb{C}\otimes AH$ where $\mathbb{C}$ is viewed as an A-algebra via the ring homomorphism $A@>>>\mathbb{C},v\mapsto c$. Now H_c is also referred to as an Iwahori-Hecke algebra.

(a) {\it Show that the algebras associated in [S20] to a supercuspidal representation of a parabolic subgroup of a p-adic reductive group are (up to extension by a group algebra of a small finite group) of the form H_q where q is a power of p, with H associated to an affine Weyl group W and with L in the collection Σ_W of weight functions on W described in [L91, \mathbb{S]17}, [L95], [L02].} \newline For example, if W is of affine type F_4, then Σ_W consists of all L whose values on $\{s_i;i\in I\}$ are $(1,1,1,1,1)$ or $(1,1,1,2,2)$ or $(2,2,2,1,1)$ or $(1,1,1,4,4)$; if W is of affine type G_2, then Σ_W consists of all L whose values on $\{s_i;i\in I\}$ are $(1,1,1)$ or $(1,1,3)$ or $(3,3,1)$ or $(1,1,9)$.

The statement analogous to (a) for groups with connected centre over a finite field F_q instead of p-adic groups is known to hold, without the words in parenthesis; in that case, W is a Weyl group and Σ_W consists of the weight functions on W described in [L78, p.35].

背景链接：https://arxiv.org/abs/2006.08535

02116 | AMR-124-0002

Iwahori-Hecke Algebras - Problem 2

O / open | AMR 问题清单汇编

There is a unique group homomorphism $\bar{}:H@>>>H$ such that $\overline{v^nT_w}T_{w\i}=v^{-n}$ for $n\in\mathbb{Z},w\in W$; it is a ring isomorphism. Let $H_{\le0}=\sum_{w\in W}\mathbb{Z}[v -]T_w\subset H$. For any $w\in W$ there is a unique element $c_w\in H_{\le0}$ such that $\bar c_w=c_w$ and $c_w-T_w\in v - H_{\le0}$ (see [KL],[L03]). Then $\{c_w;w\in W\}$ is an A-basis of H. For x,y,z in W we define $f_{x,y,z}\in A$, $h_{x,y,z}\in A$ by $T_xT_y=\sum_{z\in W}f_{x,y,z}T_z$, $c_xc_y=\sum_{z\in W}h_{x,y,z}c_z$.

(b) {\it Show that there exists an integer $N\ge0$ such that for any x,y,z in W we have $v^{-N}f_{x,y,z}\in\mathbb{Z}[v -]$.} \newline (See [L03, 13.4].) If W is finite this is obvious. If W is an affine Weyl group, this is known.

We will now assume that (b) holds. With N as in (b), we see that $v^{-N}h_{x,y,z}\in\mathbb{Z}[v -]$ for any x,y,z in W. It follows that for any $z\in W$ there is a unique integer $a(z)\ge0$ such that $h_{x,y,z}\in v^{a(z)}\mathbb{Z}[v -]$ for all x,y in W and $h_{x,y,z}\notin v^{a(z)-1}\mathbb{Z}[v -]$ for some x,y in W. Hence for x,y,z in W there is a well defined integer $\gamma_{x,y,z\i}$ such that $h_{x,y,z}=\gamma_{x,y,z\i}v^{a(z)}\mod v^{a(z)-1}\mathbb{Z}[v -]$. Let J be the free abelian group with basis $\{t_w;w\in W\}$. For x,y in W we set $t_xt_y=\sum_{z\in W}\gamma_{x,y,z\i}t_z$. (This is a finite sum.)

(c) *Show that this defines an (associative) ring structure on J (without 1 in general).* \newline Assume now that W is a Weyl group or an affine Weyl group and $L=|$. In this case, (c) is known to be true and the ring J does have a unit element.

More generally, assume that W is an affine Weyl group and $L\in\Sigma_W$ (see (a)); in this case there is a (conjectural) geometric description [L16, 3.11] of the elements c_w. From this one should be able to deduce (c) as well as the well-definedness of the $\mathbb{C}$-algebra homomorphism $H_q@>>>\underline J$ in [L03, 18.9], where H_q is as in (a) and $\underline J=\mathbb{C}\otimes J$ is independent of q. One should expect that the irreducible (finite dimensional) $\underline J$-modules, when viewed as H_q-modules, form a basis of the Grothendieck group of H_q-modules. (This is indeed so if $L=|$.) This should provide a construction of the ``standard modules'' of H_q which, unlike the construction in [L95],[L02], does not involve the geometry of the dual group.

02117 | AMR-124-0003

Iwahori-Hecke Algebras - Problem 3

O / open | AMR 问题清单汇编

Assume that W is finite and that $L=||$. Let C be a conjugacy class in W; let C_{min} be the set of all $w\in C$ such that $|w|$ is minimal. For $w\in C$ let $N^w\in A$ be the trace of the A-linear map $H@>>>H$, $h\mapsto v^{2|w|}T_whT_{w\i}$. We have $N^w\in\mathbb{Z}[v^2]$. (Note that $N^w|_{v=1}$ is the order of the centralizer of w in W.) From [GP] one can deduce that for $w\in C_{min}$, N^w depends only on C, not on w. We say that C is *positive* if $N^w\in\mathbb{N}[v^2]$. For example, if C is an elliptic regular conjugacy classes (in the sense of [S74]) then C is positive (see [L18]). If W is of type A_n, the positive conjugacy classes are $\{1\}$ and the class of the Coxeter element. In the case where W is a Weyl group of exceptional type a complete list of positive conjugacy classes in W is given in [L18].

(d) *Make a list of all positive conjugacy classes in W assuming that W is a Weyl group of type B_n or D_n.*

Kisin's framed Breuil-Mezard multiplicity conjecture

S / solved | AIM 研讨会问题汇编

Conjecture 2 (Kisin), recovered. The Hilbert--Samuel multiplicity of \[R^{\square,\psi}(k,\tau,\bar\rho)/(\varpi) \] is equal to \(\mu_{\mathrm{Aut}}(k,\tau,\bar\rho)\).

Colmez's functor and an expectation.' The actual record ends there. It is not part of Conjecture 2 and is not treated as an assigned problem here.

The source first fixes an inertial Galois type \(\tau:I_{\mathbf Q_p}\to\mathrm{GL}_2(E)\), a residual representation \(\bar\rho\), a determinant datum \(\psi\), and the potentially semistable framed deformation quotient. Its statement is:

Here \(k\geq 2\) specifies Hodge--Tate weights \((0,k-1)\), \(\varpi\) is a uniformizer of the coefficient ring, and \[\mu_{\mathrm{Aut}}(k,\tau,\bar\rho) =\sum_{0\leq n\leq p-1\atop 0\leq m\leq p-2} a(n,m)\,\mu_{n,m}(\bar\rho), \] where \(a(n,m)\) is the multiplicity of \(\sigma_{n,m}=\operatorname{Sym}^n\mathbb F^2\otimes\det^m\) in the semisimplified reduction of a stable lattice \(L_{k,\tau}\).

- the control character U+0003 after \(R\) is the lost framed symbol \(\square\); - the final argument is the residual representation \(\bar\rho\), whose bar is lost in the extraction; - the source's \(\pi\) is written \(\varpi\) to avoid confusion with a representation; - \(\mu_{\mathrm{Aut}}\) is restored with its arguments; - the source PDF itself displays the framed symbol imperfectly in text extraction, but its definition as the universal **framed** deformation ring makes the reconstruction unambiguous.

The PDF also warns that these notes were typeset on the fly and may contain transcription errors. This recovery uses only the paragraph ending immediately before section 1.2.

Linear Jordan-block bounds and a counterexample to the literal nonbacktracking Alon--Boppana claim

P / partially_solved | AIM 研讨会问题汇编

The exact statement is:

The AIM page does **not** specify four material conventions.

1. **Simple versus multi-graph.** The later papers used below explicitly work with finite simple undirected graphs. All proved claims and the counterexample in this report use that convention. 2. **Connectedness.** The page says “any graph” and imposes no connectedness condition. This omission is decisive for part (2). 3. **No leaves.** Literally, a leaf is a degree-one vertex, so “no leaves” permits isolates. Heysse, Lorenzen, and Reinhart (2025) instead describe the intended defectiveness problem as one for graphs of minimum degree at least two. Results below distinguish these readings. 4. **Second modulus and the error term.** For the nonnormal matrix B_G, define $$ |\lambda|_1(B_G)\ge |\lambda|_2(B_G)\ge\cdots $$ by listing complex eigenvalues with algebraic multiplicity and sorting their moduli. The counterexample below has a unique eigenvalue outside a fixed circle, so it also works if the second *distinct* modulus is intended. The expression $o_n(1)$ is interpreted in the only nonvacuous all-graph sense: a single error sequence $\varepsilon_n\to0$ must work uniformly for every graph in the stated n-vertex class.

02162 | AMR-130-0001

Linear Systems and Eigenvalue Problems - Problem 1

O / open | AMR 问题清单汇编

We propose focusing the benchmark problems on linear systems that are discretizations of partial differential equations (PDEs) due to both their wide application in science and engineering and to their connection to graph Laplacians that have been a focus of TCS research in linear system solvers. Furthermore, matrix collections such as the SuiteSparse collection [DavisHu2011] provide a set of matrices, but they do not provide a pipeline that defines parametrized discretizations of model problems from which a large set of such sample matrices could be generated. Parameterized classes of problems are important to understand the range of characteristics and behaviors that a solver might encounter for a class of problem.

We therefore propose the following two problems.

Develop software to generate benchmark parameterized linear systems that are generally accepted as relevant in practice and suitable for theoretical analysis.

02164 | AMR-130-0011

Linear Systems and Eigenvalue Problems - Problem 11

O / open | AMR 问题清单汇编

Another reason for focusing on condition number reduction rather than ``improving'' the entire eigenvalue distribution by preconditioning is that the eigenvalue distribution is usually unknown in practical applications. Yet, the recent line of work in [GerMadNieStr19,GerNieStr20,GerNieStr22,NieStr24] has shown that for certain elliptic PDE model problems, for example $-\nabla\cdot (k(x)\nabla u)=f$ with $k(x)$ being a measurable, bounded, and uniformly positive function from ${\mathbb{R}}^d$ to ${\mathbb{R}}$, one can obtain the exact localization of the eigenvalues of the discretized operators (i.e., the matrices), and of the left-preconditioned matrices under Laplacian preconditioning. This approach yields new insights into the convergence of CG for the preconditioned systems.

Several specific open problems that exist in this context are mentioned in [NieStr24, Section 9]. More generally, try to extend the approach in [GerMadNieStr19,GerNieStr20,GerNieStr22,NieStr24] to other types of PDEs or preconditioners.

02165 | AMR-130-0012

Linear Systems and Eigenvalue Problems - Problem 12

O / open | AMR 问题清单汇编

The behavior of iterative methods such as GMRES for solving nonsymmetric (more precisely, nonnormal) linear algebraic systems is much less understood than the behavior of CG. In general, the performance in this case may depend not only on the eigenvalue distribution, but also on further quantities including the conditioning of the eigenvectors of A, which motivates considering ϵ-pseudospectra or the field of values of A in the convergence analysis; see, e.g., [LieStr13, Section 5.7] for a survey of results. Despite numerous existing approaches, the following problem is largely open (cf. also [Emb22]):

Develop a descriptive convergence bound for GMRES applied to nonnormal linear algebraic systems, that particularly describes the (transient) behavior early in the iteration.

Linear Systems and Eigenvalue Problems - Problem 13

O / open | AMR 问题清单汇编

Find an interesting (nonselfdajoint resp. nonsymmetric) model problem, where the theoretical result on the eigenvalue distribution of the preconditioned matrix indeed corresponds to the actual convergence behavior of GMRES (e.g., $M^{-1}A$ has m eigenvalue clusters and an acceptable approximate solution is obtained by GMRES in ${\mathcal{O}}(m)$ steps). Determine which particular properties of the problem implied this correspondence.

02168 | AMR-130-0015

Linear Systems and Eigenvalue Problems - Problem 15

O / open | AMR 问题清单汇编

A number of methods for solving linear systems (with or without a preconditioner) can be implemented in the following form: Starting with an initial guess x_0 for the solution to $Ax=b$, for $k=1,2, \ldots$, set \begin{eqnarray*} x_k & = & x_{k-1} + a_{k-1} p_{k-1} \\ r_k & = & r_{k-1} - a_{k-1} A p_{k-1} . \end{eqnarray*} The updated vectors r_k are not the true residuals $b-A x_k$ when these formulas are implemented in finite precision arithmetic. It is pointed out in [Greenbaum97] that these vectors often shrink well below the machine precision, and this is used to prove results about the size of the true residuals. But this is not proved.

Taking the above recurrences to represent the CG or steepest descent algorithm, determine conditions on A that will insure that the norms of the vectors r_k drop below the machine precision in finite precision arithmetic or show some examples where they do not.

02197 | AMR-130-0005

Linear Systems and Eigenvalue Problems - Problem 5

O / open | AMR 问题清单汇编

Complexity for sparse matrices. Importantly, the matrix-vector product model is most relevant for sparse matrices, in which case the extra cost paid by the Krylov solver is only $\tilde O(\mathrm{nnz}(A)\cdot k)$, where $\mathrm{nnz}(A)$ is the number of non-zero entries in A (although, importantly, additional costs arise in finite precision arithmetic). Many randomized linear algebra methods can also leverage input sparsity for faster running time, so it is natural to expect that a similar improvement may be attainable in the direct access model.

Can we solve an $(n,k,0,\kappa)$ linear system $Ax=b$ to high accuracy using $\tilde O(k^\omega + \mathrm{nnz}(A)\kappa)$ arithmetic operations?

Maximal-degree characters from rank vectors

P / partially_solved | AIM 研讨会问题汇编

The AIM problem list for the workshop *Supercharacters and combinatorial Hopf algebras* gives:

The PDF places a line break after “super-”.

The phrase “as supercharacters” is potentially stronger than merely asking for large constituents of supercharacters. This report distinguishes:

1. ordinary irreducible characters of maximal degree; 2. standard Diaconis--Isaacs supercharacters which happen to be irreducible; 3. the degree of a reducible supercharacter.

They need not agree for a general pattern group. The main theorem below gives a class in which they do agree completely.

Open Problems in the Theory of Ample Fields - Question 1

O / open | AMR 问题清单汇编

Our first question can be simply stated as follows.

Is $\mathbb{Q}_\mathrm{ab}$ ample?

背景链接：https://arxiv.org/abs/1106.1310

02266 | AMR-139-0003

Open Problems in the Theory of Ample Fields - Question 3

O / open | AMR 问题清单汇编

Colliot-Th\'el\`ene observed that a field K is ample whenever G_K is a pro-p group for some prime number p, [ColliotThelene,JardenAmple]. This covers again in particular the archimedean local fields $\mathbb{R}$ and $\mathbb{C}$. Since pro-p groups are prosolvable, and all local fields have prosolvable absolute Galois groups we want to ask for the following generalization of Colliot-Th\'el\`ene's result:

Is every infinite field K with prosolvable absolute Galois group G_K ample?

背景链接：https://arxiv.org/abs/1106.1310

02267 | AMR-139-0004

Open Problems in the Theory of Ample Fields - Question 4

O / open | AMR 问题清单汇编

Another Galois theoretic property that the local fields ${\mathbb{Q}}_p$, $\mathbb{R}$, and $\mathbb{C}$ share, apart from having a prosovable absolute Galois group, is that their absolute Galois groups are all finitely generated (as topological groups). The following question occurs as a conjecture in [JunkerKoenigsmann]:

Is every infinite field K with finitely generated absolute Galois group G_K ample?

背景链接：https://arxiv.org/abs/1106.1310

02268 | AMR-139-0005

Open Problems in the Theory of Ample Fields - Question 5

O / open | AMR 问题清单汇编

Trivially, every ample field is virtually ample, and every virtually ample field is weakly ample. One could think that every virtually ample field should be ample, but no proof is known. As evidence one usually refers to the fact that similar descent properties hold for Henselian valued fields. We want to ask more generally:

What is the relation between ample, virtually ample, and weakly ample fields? Is every weakly ample field virtually ample? Is every virtually ample field ample?

Open Problems on Central Simple Algebras - Conjecture 39

O / open | AMR 问题清单汇编

The ``if'' direction can be found in [Vos, p. 186]. The full theorem amounts to combining the results from ibid.\ with [Gille:KT, Th. 5.9]. Gille's theorem furthermore shows that the conditions are equivalent to the abstract group $\operatorname{SL}_r(A)(L)$ being ``projectively simple'' for every extension L/F and every $r \ge 2$.

The main problem from this point of view is to prove the following converse to Wang's result:

[Suslin \protect{[Suslin:SK1, p. 75]}] If $\operatorname{SK}_1(A \otimes L) = 0$ for every extension L/F, then the index of A is square-free.

02276 | AMR-136-0010

Open Problems on Central Simple Algebras - Problem 10

O / open | AMR 问题清单汇编

And one can ask the weaker question:

Is $\operatorname{Br}_p[n](F)$ generated by algebras of degree n?

背景链接：https://arxiv.org/abs/1006.3304

02277 | AMR-136-0011

Open Problems on Central Simple Algebras - Problem 11

O / open | AMR 问题清单汇编

Suppose m and n have the same prime factors, $m\mid n$, and $\operatorname{Br}_p[m](F)$ is generated by cyclic algebras. Let $\ell_F(m,n)$ denote the minimal number such that every central simple F-algebra of degree n and period (dividing) m is similar to a tensor product of $\ell_F(m,n)$ cyclic algebras of degree m, unless no such bound exists, in which case set $\ell_F(m,n)=\infty$. If F contains the m-th roots of unity, the generic division algebra can be used to show that $\ell_F(m,n)$ is finite, by the Merkurjev--Suslin theorem. In this case, we may assume m is a power of a prime p by [Tig84, Th. 2.2], and $\ell_F(m,n)$ is known as the *symbol length*.

Suppose p is a prime, $r\leq s$, and $\operatorname{Br}_p[p^r](F)$ is generated by cyclic algebras. Compute $\ell_F(p^r,p^s)$.

02278 | AMR-136-0012

Open Problems on Central Simple Algebras - Problem 12

O / open | AMR 问题清单汇编

If F is finitely generated over a field F_0 with $\operatorname{Br.\!dim}(F_0)$ finite, is $\operatorname{Br.\!dim}(F)$ necessarily finite?

It is natural to start by considering only certain fields F_0. For example, suppose that F has prime characteristic p and we take F_0 to be its prime field, so $\operatorname{Br.\!dim}(F_0) = 0$. If F has transcendence degree 1 over F_0, then F is global and $\operatorname{Br.\!dim}(F) = 1$. If F has transcendence degree 2 over F_0, then $\operatorname{Br.\!dim}(F) \le 3$ by [Lieblich:PI].

背景链接：https://arxiv.org/abs/1006.3304

02279 | AMR-136-0013

Open Problems on Central Simple Algebras - Problem 13

O / open | AMR 问题清单汇编

Define a notion of ``dimension'' for some class of fields F such that \[\operatorname{Br.\!dim}(F) \le \dim F - 1 \quad \text{and} \quad \dim(F(t)) = \dim F + 1. \] One possibility would be to set a C_i field to have dimension i. The notion of cohomological dimension is obviously not the right one in view of Merkurjev's example of a field F with cohomological dimension 2 and $\operatorname{Br.\!dim}(F) = \infty$ from [M:simple].

背景链接：https://arxiv.org/abs/1006.3304

02280 | AMR-136-0014

Open Problems on Central Simple Algebras - Problem 14

O / open | AMR 问题清单汇编

To simplify the discussion note the result of Katsylo [Katsylo] and Schofield [Schofield] that if $n = ab$ for a and b relatively prime, then $Z(F,n)$ is stably isomorphic to the field compositum $Z(F,a) Z(F,b)$. Similar statements are possible for the $Z_m(F,n)$ and $Z_H(F,n)$. This often (but not always) allows reduction to the case where n is a prime power.

[procesi:67, p. 240] Is $Z(F,n)/F$ rational, stably rational, or retract rational? The same question for $Z_m(F,n)$ and $Z_H(F,n)$.

背景链接：https://arxiv.org/abs/1006.3304

02281 | AMR-136-0015

Open Problems on Central Simple Algebras - Problem 15

O / open | AMR 问题清单汇编

There are a few results for the $Z_m(F,n)$. The field $Z_2(F,4)$ is stably rational by Saltman [Salt:symp], and Saltman--Tignol [SaltTig] showed that $Z_2(F,8)$ is retract rational. Beneish [Beneish:28] showed that $Z_2(F,8)$ is stably rational. Finally, we leave to the well-read reader to prove that when $H \subset S_n$ is cyclic and transitive and F contains a primitive n-th root of unity, then $Z_H(F,n)$ is rational (and results *are* available for general F, n not of the form $8m$, and retract rationality). Thus the first interesting specific question along these lines is:

Determine if $Z_H(F,9)$ is rational, stably rational, or retract rational, where

$H = C_3 \times C_3 \subset S_9$ is transitive.

Open Problems on Central Simple Algebras - Problem 7

O / open | AMR 问题清单汇编

{\textrm{[Albert:cyclics, p. 126]}} Is the n-torsion subgroup $\operatorname{Br}_p[n](F)$ generated by the classes of cyclic algebras of degree (dividing) n?

背景链接：https://arxiv.org/abs/1006.3304

02304 | AMR-136-0008

Open Problems on Central Simple Algebras - Problem 8

O / open | AMR 问题清单汇编

- *F contains a primitive n-th root of unity.* This was pointed out above. The Merkurjev-Suslin theorem, which establishes an isomorphism between $K^M_2(F) / nK^M_2(F)$ and ${\text\mathrm{H}}^2(F,\mu_n^{\otimes 2})$, is now a special case of the recently-proved Bloch--Kato Conjecture.

The smallest open case for n prime is therefore:

Is $\operatorname{Br}_p[7](F)$ generated by cyclic algebras of degree 7 when $\operatorname{char} F\neq 7$ and F does not contain a primitive 7-th root of unity?

背景链接：https://arxiv.org/abs/1006.3304

02305 | AMR-136-0009

Open Problems on Central Simple Algebras - Problem 9

O / open | AMR 问题清单汇编

(These problems are related to the following very special question stated by M. Mahdavi-Hezavehi: \emph{If the multiplicative group $F^\times$ is divisible, does it follow that $\operatorname{Br}(F)$ is zero?} The answer is ``yes'' if $\operatorname{Br}(F)$ is generated by cyclic algebras, because cyclic algebras are split over such a field. Therefore the answer is also ``yes'' if F has characteristic zero, because in that case F has all the roots of unity so the Merkurjev--Suslin theorem applies.)

For composite n, even the following is unclear:

Is $\operatorname{Br}_p[4](F)$ generated by cyclic algebras of degree 4 when $\operatorname{char} F \neq 2$ and $\sqrt{-1} \not\in F$?

Open Problems on Ind-Groups of Automorphisms

O / open | Oberwolfach 报告问题汇编

Let X be an affine variety. Determine whether the following assertions hold. First, if $G\subseteq\operatorname{Aut}(X)$ is connected and closed and $N\triangleleft G$ is proper and closed, then $\operatorname{Lie}(N)\subsetneq\operatorname{Lie}(G)$. Second, if closed subgroups $H,G\subseteq\operatorname{Aut}(X)$ satisfy that G is connected, $\operatorname{Lie}(G)\subseteq\operatorname{Lie}(H)$, and every element of G is algebraic, then $G\subseteq H$. Third, a closed subgroup consisting of algebraic elements, and more generally the closure of any such subgroup, is nested. Fourth, if $\operatorname{Aut}(X)^\circ$ is nontrivial, it contains a positive-dimensional algebraic subgroup. Fifth, the normalizer of the tame subgroup $\langle\operatorname{SAff}_n,\operatorname{SJonq}_n\rangle$ is dense in $\operatorname{SAut}(\mathbb A^n)$.

02445 | AIM-REPRESENTATION_THEORY-0112

Serre weights and complete Hecke packets

P / partially_solved | AIM 研讨会问题汇编

The section declares \(p>2\) and uses arithmetic Frobenius. Its goal is to generalize the weight part of Serre's conjecture from \(\mathrm{GL}_2/\mathbf Q\) to \(\mathrm{GL}_n/\mathbf Q\).

The mathematical content of Conjecture 5 is recovered as follows. Let \[\bar\rho:G_{\mathbf Q}\longrightarrow \mathrm{GL}_2(\overline{\mathbf F}_p) \] be continuous, odd, and irreducible, let \(p\nmid N\), and let \(\sigma\) be a finite-dimensional characteristic-\(p\) representation of \(\mathrm{GL}_2(\mathbf F_p)\). Then \[H^1(\Gamma_1(N),\sigma) \] should contain a Hecke eigenclass on which \[T_\ell\quad\text{acts by}\quad \operatorname{tr}\bar\rho(\operatorname{Frob}_\ell) \qquad(\ell\nmid Np) \] if and only if \[N(\bar\rho)\mid N, \qquad \operatorname{JH}(\sigma)\cap \operatorname{Wt}(\bar\rho|_{I_p})\ne\varnothing. \tag{1.1} \] The notes then ask how to generalize this and begin the Ash--Sinnott/Ash--Doud--Pollack setup: take an irreducible \(\bar\rho:G_{\mathbf Q}\to\mathrm{GL}_n(\overline{\mathbf F}_p)\) satisfying \[\left|\dim \bar\rho(c)^{+1}-\dim \bar\rho(c)^{-1}\right|\le 1, \tag{1.2} \] define its prime-to-\(p\) conductor \(N(\bar\rho)\) and a set of Serre weights, and set \[\Gamma_1(N)=\left\{g\in\mathrm{SL}_n(\mathbf Z): g\equiv \begin{pmatrix} *&*\\0&1\end{pmatrix}\pmod N\right\}. \tag{1.3} \] Here the lower-left block is a zero row of length \(n-1\), so equivalently the last row is congruent to \((0,\ldots,0,1)\). For \(\ell\nmid Np\), the record ends with the complete displayed definition \[T_\ell= \left[\Gamma_1(N)\operatorname{diag}(\ell,1,\ldots,1)\Gamma_1(N)\right]. \tag{1.4} \]

The next sentence of the PDF begins the separately numbered Conjecture 6, which asks for an eigenclass in \(H^d\) for some degree \(d\). Thus record 0112 really does end at (1.4). The nearby continuation is needed to understand what the setup was preparing, but it is not part of this record and is not reproduced as its claimed statement.

The source asks five related questions. In exact mathematical terms:

1. For $$ \mathcal P_d=\left\{\sum_{j=0}^d a_jz^j:a_j\ge0, \text{ and every zero is real}\right\}, $$ classify functions $F:[0,\infty)\to[0,\infty)$ with $F(0)=0$ for which $$ F[f](z)=\sum_{j=0}^d F(a_j)z^j $$ remains in $\mathcal P_d$. Equivalently, the source phrases this as entrywise preservation of total nonnegativity of the lower-triangular Toeplitz matrix $T_{\mathbf a}$. 2. Ask the same question for fixed d. The natural reading is therefore that item (i) asks for preservation uniformly over all finite degrees. 3. Replace either the input or output ordinary generating polynomial, or both, by the exponential normalization $$ \sum_{j=0}^d \frac{a_jz^j}{j!}, $$ giving four ordinary/exponential cases. 4. Allow a coefficient weight $g(j)$: $$ F_g[f](z)=\sum_{j=0}^d g(j)F(a_j)z^j. $$ 5. Classify local rules $$ F_h[f](z)=\sum_{j=0}^d h(a_{j-1},a_j,a_{j+1})z^j, \qquad a_{-1}=a_{d+1}=0, $$ beyond the Turan rule $h(x,y,z)=y^2-xz$, and ask about higher-order determinants.

- Since the coefficients are nonnegative, every real zero of a nonzero polynomial is automatically nonpositive. - The logical definition in the source excludes the zero polynomial: it vanishes at nonreal numbers. In contrast, the zero Toeplitz matrix is totally nonnegative. Thus the stated equivalence implicitly uses the common PF/TN convention that the zero sequence is allowed. Below, zero-map statements are labeled by convention; all main constructive results use a positive scale and produce a nonzero polynomial. - The polynomial formulation permits zero coefficients, while the displayed Toeplitz formulation takes $\mathbf a\in(0,\infty)^{d+1}$. For arbitrary discontinuous F, these are not automatically interchangeable as test domains. The degree-two results below use the literal nonnegative-coefficient polynomial formulation and handle vanishing coefficients directly.

The dual NCSym realization and its internal coproduct

P / partially_solved | AIM 研讨会问题汇编

Describe explicitly the Hopf isomorphism $$ SC^{(2)*}\longrightarrow \Pi^*\cong\Pi QSym $$ in these two presentations, and make it compatible with an internal comultiplication.

Its key fragments are

Comparing the display with the later polynomial realization in Aguiar et al.

Let $\Pi=\mathrm{NCSym}$ be the Hopf algebra of symmetric functions in noncommuting variables. For a set partition $\mu\vdash[n]$, its monomial basis is

$$ \mathbf m_\mu=M_\mu=\sum_{\nabla\omega=\mu}\omega, \tag{1.1} $$

where $\omega\in A^*$, $A=\{a_1,a_2,\ldots\}$ is a noncommuting alphabet, and $\nabla\omega$ is the partition of the positions of ω into equal-letter classes.

For the dual polynomial realization, let the x_{ij} be commuting variables with the rook relations

$$ x_{ij}x_{ik}=0\quad(j\ne k), \qquad x_{ik}x_{jk}=0\quad(i\ne j). \tag{1.2} $$

For $\sigma\in\mathfrak S_n$, put

$$ M_\sigma=\sum_{i_1<\cdots<i_n} x_{i_1,i_{\sigma(1)}}\cdots x_{i_n,i_{\sigma(n)}} \tag{1.3} $$

$$ U_\mu=\sum_{\operatorname{csupp}(\sigma)=\mu}M_\sigma, \tag{1.4} $$

where $\operatorname{csupp}(\sigma)$ is the partition of $[n]$ whose blocks are the supports of the disjoint cycles of σ. The span of the U_μ is denoted $\Pi QSym$ and realizes Π^*.

Thus the recovered question is:

The infinite-index sum (1.3) is the rigorous published version of the abbreviated monomial in the workshop display.

There remains one genuine mathematical ambiguity: the workshop sheet does not define “internal comultiplication.” The natural operation on $SC^{(2)*}_n$ is the dual of pointwise multiplication of superclass functions in the fixed group $UT_n(2)$. This report solves that reading. The familiar internal coproduct on the primal algebra Π, if that was intended instead, dualizes to an **internal product** on Π^*, not to a coproduct; identifying the two requires extra self-duality data not specified in the question.

02553 | AMR-113-0024

The Lyapin's Notebook - Problem 25

O / open | AMR 问题清单汇编

In his book *Semigroups*, E.S. Lyapin emphasized that establishing connections between the properties of endomorphism semigroups and the properties of the underlying structured sets is one of the most important directions in semigroup theory. This direction may be viewed as a natural generalization of the ideas of Galois theory.

(E.S. Lyapin) For natural classes of mathematical structures - such as ordered sets, relatively free algebras, and for subsemigroups of endomorphism semigroups of these structures - determine:

- Subclasses of structures defined up to isomorphism by these semigroups;

- Subsemigroups of endomorphism semigroups that determine these structures up to isomorphism.

For various classes of partially ordered sets E.S. Lyapin found endomorphism semigroups that determine these classes up to isomorphism (see [Lyapin4], [L5], [L6]).

(G. Mashevitzky)

- Describe transformation semigroups that are closed in the pointwise topology.

- Describe endomorphism semigroups that are closed in a topology of Zarisky type.

Motivation and definitions can be found in [Cameron], [Mash1], [MPP], [Mash2]. Transformation semigroups closed in the pointwise topology are precisely the semigroups of endomorphisms of mathematical structures (see [Mash2]). It was shown in [Mash1] that the Zariski-type topology is weaker than the pointwise topology and conditions were obtained under which these topologies coincide. Several special cases of the problem were solved in [Mash2].

The proved Breuil-Mézard equality and a weight-support certificate

S / solved | AIM 研讨会问题汇编

Conjecture 1 (Breuil-M´ ezard). $\mu\mathrm{Gal}=\mu\mathrm{Aut}$.

Its core text is

The rest of the record says that global arguments generally give the inequality from the Galois side to the automorphic side and then introduces a framed potentially semistable deformation ring.

Let p be a prime, let $E/\mathbb Q_p$ be a sufficiently large finite extension with ring of integers $\mathcal O$, uniformizer ϖ, and residue field $\mathbb F$, and let $\bar\rho:G_{\mathbb Q_p}\to\mathrm{GL}_2(\mathbb F)$ be a residual representation. For an inertial type τ and Hodge--Tate weights $(0,k-1)$, the Galois multiplicity $\mu_{\mathrm{Gal}}(k,\tau,\bar\rho)$ is the Hilbert--Samuel multiplicity of the special fibre of the relevant potentially semistable local deformation ring. Every irreducible mod-p representation of $\mathrm{GL}_2(\mathbb Z_p)$ is inflated from a Serre weight

\[\sigma_{n,m}=\operatorname{Sym}^n\mathbb F^2\otimes\det^m, \qquad 0\le n\le p-1,\quad 0\le m\le p-2. \]

If $L_{k,\tau}$ is a stable lattice in the characteristic-zero type, write

\[(L_{k,\tau}/\varpi L_{k,\tau})^{\mathrm{ss}} \cong \bigoplus_{n,m}\sigma_{n,m}^{\,a_{k,\tau}(n,m)}. \]

Breuil and Mézard define integers $\mu_{n,m}(\bar\rho)\ge0$ and

\[\mu_{\mathrm{Aut}}(k,\tau,\bar\rho) =\sum_{n,m}a_{k,\tau}(n,m)\mu_{n,m}(\bar\rho). \]

The recovered conjecture is therefore the numerical equality

\[\boxed{\ \mu_{\mathrm{Gal}}(k,\tau,\bar\rho) =\sum_{n,m}a_{k,\tau}(n,m)\mu_{n,m}(\bar\rho)\ }. \tag{BM} \]

The reducible fiber of the representation-to-pseudorepresentation map

P / partially_solved | AIM 研讨会问题汇编

\[V_{\mathbb F}=\omega _1\oplus\omega _2\longmapsto T_{\mathbb F}, \]

and the completion appearing later is \(\widehat R_x\). The final token “8.3.” belongs to the next subsection, whose separate problem asks for cohomological tools for pseudorepresentations; it is not part of Problem 2.

With those corrections, but without supplying definitions absent from the notes, the problem is the following. Let \(\mathbb F\) be a finite field, let \(\omega _1\ne\omega _2\) be characters, and let \(T_{\mathbb F}\) be the pseudorepresentation attached to the semisimple representation \(\omega _1\oplus\omega _2\). Study representations over \(W(\mathbb F)\)-algebras whose residual representation is a non-split extension of \(\omega _1\) by \(\omega _2\). The notes propose a morphism

\[X_{\omega _2}\longrightarrow \operatorname{Spec}R(T_{\mathbb F}) \]

whose special fiber involves

\[\bigl(\operatorname{Ext}^1(\omega _1,\omega _2)\setminus\{0\}\bigr) /\mathbb F^\times. \]

A point \(x\) of that fiber should determine an extension \(V_x\), and the completion \(\widehat R_x\) is suggested to be the universal deformation ring of \(V_x\). A universal rank-two bundle \(V_{\omega _2}\) on \(X_{\omega _2}\) is proposed, as is a bundle \(\pi^*V_{\omega _2}\) on the pseudodeformation space. The notes then put \(X_{\omega _2}\) and the opposite-extension space \(X_{\omega _1}\) over the same base and ask whether they can be glued “along the trivial extension,” perhaps into an algebraic stack. They also assert, without giving the construction of \(X_{\omega_i}\), that \(X_{\omega_2}\) is proper by the valuative criterion.

The square-energy bound is proved, while the proposed edge-addition monotonicities fail

P / partially_solved | AIM 研讨会问题汇编

Consider a connected graph G with adjacency eigenvalues $$ \lambda_1\geq\cdots\geq\lambda_s\geq0>\lambda_{s+1}\geq\cdots\geq\lambda_n $$ and $$ S^+(G)=\sum_{i=1}^s\lambda_i^2, \qquad S^-(G)=\sum_{i=s+1}^n\lambda_i^2. $$ It contains four items:

1. prove $\min\{S^+(G),S^-(G)\}\geq n-1$; 2. after ordering the complement edges as $e_1,\ldots,e_\ell$ and setting $G_i=G+\{e_1,\ldots,e_i\}$, prove that $S^+(G_i)$ is nondecreasing and $S^-(G_i)$ is unimodal; 3. ask whether $\sum_{t=1}^r\lambda_t(G_i)^2$ is nondecreasing for every $r\geq1$; 4. ask whether $\sum_{t:\lambda_t(G_i)\geq\tau}\lambda_t(G_i)^2$ is nondecreasing for a fixed threshold τ.

It defines the positive and negative square energies using strictly positive and strictly negative eigenvalues and records the $n-1$ conjecture and the one-edge S^+ conjecture.

Following the AIM report and all primary papers checked, graphs are taken to be finite, simple, undirected, and unweighted.

The natural and useful reading of item 2 is universal over complement-edge orderings. We set $G_0=G$. “Unimodal” means the standard peak convention: for some j, $$ a_0\leq\cdots\leq a_j\geq\cdots\geq a_\ell. $$ This is also the convention required by the source's claimed implication to item 1. The counterexamples below violate these statements in a prefix and therefore remain counterexamples after the remaining complement edges are appended in any order.

Let A,B be positive semidefinite, by Jensen's inequality, it is easy to see $[tr(A^s+B^s)]^{\frac{1}{s}}\leq [tr(A^r+B^r)]^{\frac{1}{r}}$, whenever $s>r>0$.

What about the $tr(A^s+B^s)^{\frac{1}{s}}\leq tr(A^r+B^r)^{\frac{1}{r}}$, is it still valid?

Waring rank of determinant

P / partially_solved | Open Problem Garden

Question What is the Waring rank of the determinant of a $d \times d$ generic matrix?

For simplicity say we work over the complex numbers. The $d \times d$ generic matrix is the matrix with entries $x_{i,j}$ for $1 \leq i,j \leq d$. Its determinant is a homogeneous form of degree d, in d^2 variables. If F is a homogeneous form of degree d, a power sum expression for F is an expression of the form $F = \ell_1^d+\dotsb+\ell_r^d$, the ℓ_i (homogeneous) linear forms. The Waring rank of F is the least number of terms r in any power sum expression for F. For example, the expression $xy = \frac{1}{4}(x+y)^2 - \frac{1}{4}(x-y)^2$ means that xy has Waring rank 2 (it can't be less than 2, as $xy \neq \ell_1^2$).

The 2×2 generic determinant $x_{1,1}x_{2,2}-x_{1,2}x_{2,1}$ (or $ad-bc$) has Waring rank 4. The Waring rank of the 3×3 generic determinant is at least 14 and no more than 20, see for instance Lower bound for ranks of invariant forms, Example 4.1. The Waring rank of the permanent is also of interest. The comparison between the determinant and permanent is potentially relevant to Valiant's "VP versus VNP" problem.

A coefficient-sampling reduction for lattice descent of rapid decay

P / partially_solved | AIM 研讨会问题汇编

The database record has accidentally concatenated all of Sections 1 and 2, page numbers, and the heading of Section 3.

- **Section 1, RD for cocompact lattices**, consists of items 1--7: the generalized Valette conjecture; invariance between two uniform lattices in one ambient group (and a measurable-topological-coupling version); the obstruction for many nonuniform lattices; a request for a relative version of RD; descent to a cocompact normal subgroup; permanence in a short exact sequence; and the proposed `(**)`-relative-hyperbolicity approach. - **Section 2, RD for unitary representations**, consists of Definition 2.1 and items 1--5, including Cowling's quasi-regular-representation remark. - The final words "3 RD for length functions" are only the next section heading. Section 3 is the next canonical corpus record (source index 166), and is not part of the mathematics considered here.

The principal question, quoted with only punctuation normalized, is:

The source calls this the generalized Valette conjecture. The original Valette conjecture asks for RD of uniform lattices in semisimple groups over local fields. The short-exact-sequence question is:

\[1\longrightarrow H\longrightarrow \Gamma\longrightarrow P \longrightarrow 1, \qquad P\text{ has RD}; \]

is \(\Gamma\) RD if and only if \(H\) is RD for the restriction of a word length of \(\Gamma\)?

1. "locally compact compactly generated" means "locally compact, compactly generated"; the word *compact* is not duplicated. 2. `S0(2,3)` is \(SO(2,3)\). The displayed equality with \(Sp(4,\mathbb R)\) is not literal: one should use the identity component and central isogeny, for example \(PSp(4,\mathbb R)\cong SO_0(2,3)\). 3. The notation \(SL(3,\mathbb O)\) is informal. The exceptional real case in Chatterji's theorem is the symmetric space associated with \(E_{6(-26)}\), alongside \(SL_3(\mathbb H)\). 4. The isolated `1`, `2`, and `22.` are page-number contamination, not mathematical exponents or item numbers. 5. The extracted Definition 2.1 loses the squared modulus and even retains the impossible phrase "and every \(g\)" after integrating over \(g\). The standard intended coefficient formulation, confirmed in Boyer's later paper, is: a unitary representation \(\pi\) has RD with respect to \(L\) if, for some \(s,C>0\), \[\int_G \frac{|\langle \pi(g)v,w\rangle|^2} {(1+L(g))^{2s}}\,d\mu(g)\le C \] for all unit vectors \(v,w\). Replacing \(2s\) by \(s\) is the same convention after renaming the exponent. The literal unsquared complex integral is not a usable definition of RD.

02698 | AIM-GEOMETRIC_GROUP_THEORY-0001

A finite height-kernel case of the quasiconvex-subgroup conjecture

P / partially_solved | AIM 研讨会问题汇编

A subgroup \(F\) of a group \(G\) is a *semi-fibre* if there exists an injective non-surjective homomorphism \(\varphi:F\to F\) such that \(G\) is the HNN extension \(G=F*_{\varphi}\). A subgroup \(F\) of \(G\) is a *virtual semi-fibre* if there exists a finite-index subgroup \(G'\) of \(G\) such that \(F\) is a semi-fibre of \(G'\).

Let \(G\) be a hyperbolic free-by-cyclic group and \(H\) a non-quasiconvex subgroup of \(G\). Then \(H\) contains a subgroup \(F\) which is a virtual fibre or a virtual semi-fibre of a free-by-cyclic subgroup of \(G\).

Its statement is:

There are two source issues that matter mathematically.

The AIM workshop report instead formulates the motivating problem for a **distorted** subgroup, and the later precise formulation in Linton's Conjecture 1.3 explicitly assumes that \(H\) is finitely generated. In a hyperbolic group, quasiconvex subgroups are finitely generated, so every infinitely generated subgroup is automatically non-quasiconvex. Thus omitting finite generation makes the literal statement substantially stronger, not merely stylistically different. All results below are stated for the intended finitely generated reading; no claim is made that the literal unrestricted statement is false.

The partial theorem below uses the still narrower atoroidal fully irreducible case exactly where an existing quasiconvexity theorem is needed. The height-kernel lemma itself has no irreducibility hypothesis.

Write \[G=F_n\rtimes_{\phi}\langle t\rangle, \qquad p:G\longrightarrow \mathbb Z, \] where \(p(t)=1\) and \(p(F_n)=0\). For \(H\leq G\), its **height kernel** is \[K_H=H\cap F_n=\ker(p|_H). \]

P / partially_solved | AIM 研讨会问题汇编

Is non-amenability of a topological full group preserved under taking restrictions?

To be more precise: let \(G\) act on a Cantor set \(C\) minimally. Assume \(G\) is equal to its full group and is non-amenable.

Take a clopen subset \(U\) of the Cantor set \(C\), let \(G_U\) be the restriction of \(G\) to \(U\). Is \(G_U\) also non-amenable?

whenever \(h\in\operatorname{Homeo}(C)\) has a finite clopen partition \(C=\bigsqcup_i C_i\) and elements \(g_i\in G\) such that \(h|_{C_i}=g_i|_{C_i}\), then \(h\in G\).

来源字段：http://aimpl.org/amenablediscrete/2/

02703 | AIM-GEOMETRIC_GROUP_THEORY-0018

A finite-index virtual-geometric nonvanishing criterion

P / partially_solved | AIM 研讨会问题汇编

Clay shows that \(\ell^2\)-torsion vanishes for free-by-cyclic groups with polynomially-growing monodromies (Clay 2017, MR3667215).

If \(G\) is a free-by-cyclic group with exponentially growing monodromy then it has non-vanishing \(\ell^2\)-torsion.

Thus the second sentence is the conjecture to be studied. Write \[G_\Phi=F_n\rtimes_\Phi\langle t\rangle =\langle F_n,t\mid t^{-1}xt=\Phi(x)\ (x\in F_n)\rangle, \] where \(\Phi\in\operatorname{Aut}(F_n)\), and put \(\phi=[\Phi]\in\operatorname{Out}(F_n)\). Following Clay's sign convention, it is useful to set \[\tau^{(2)}(G):=-\rho^{(2)}(G). \] For free-by-cyclic groups \(\tau^{(2)}(G)\geq 0\), so the conjecture asks whether exponential growth forces \(\tau^{(2)}(G)>0\).

02716 | AIM-GEOMETRIC_GROUP_THEORY-0020

A periodic non-geometric counterexample and a transfer obstruction

S / solved | AIM 研讨会问题汇编

Let G be a non-geometric free-by-cyclic group and A a finitely generated abelian group. Does there exist a finite index subgroup G' of G such that A is isomorphic to a direct summand of the abelianisation of G'?

It attributes the problem to Tam Cheetham-West and states, verbatim:

The page gives no remark, status, literature, definition of “non-geometric,” rank convention for the free kernel, or growth hypothesis on the monodromy.

There are two standard readings of “non-geometric”:

1. a specified splitting $G=F_n\rtimes_\phi\mathbb Z$ has a monodromy class $[\phi]\in\operatorname{Out}(F_n)$ that is not induced by a homeomorphism of a compact surface with boundary; 2. the abstract free-by-cyclic group is not the fundamental group of a compact surface mapping torus, equivalently in this setting is not a 3-manifold group.

The counterexample below satisfies both readings. It has a noncyclic free kernel F_3, so it is not a rank-one edge case. Its monodromy is periodic, however. If the workshop intended “exponentially growing non-geometric monodromy,” that restriction is absent from the literal source and the counterexample does not settle the strengthened version. This distinction matters because the two immediately preceding AIM problems explicitly say “exponentially growing monodromy” when that is intended.

The quantifier over finitely generated abelian A includes finite groups. This is also consistent with the surrounding literature on prescribed homological torsion. If “abelian” were intended to mean “free abelian,” the counterexample would not apply; indeed Proposition 5.5 below shows that every finite-rank free abelian group does occur in the counterexample's finite covers.

A rank transition for finite-index homomorphisms into mapping class groups

P / partially_solved | AIM 研讨会问题汇编

It is known, by Martin and Juan's results, that all the Poison groups in \(\operatorname{Out}(F_n)\) would give virtually abelian image under a homomorphism to \(\operatorname{MCG}(S)\). However, subgroups of finite index change the story.

Let \(\Gamma<\operatorname{Out}(F_n)\) have finite index. Determine \(\operatorname{Hom}(\Gamma,\operatorname{Mod}(S))\). Can such a map have infinite image, especially for \(n\geq4\)? Must its image be virtually abelian? What can be said about injectivity?

A rose-symmetry obstruction and finite-image genus range

P / partially_solved | AIM 研讨会问题汇编

Does every homomorphism \(\phi:\operatorname{Out}(F_n)\to \operatorname{MCG}(S)\) have virtually abelian image?

Its main question is:

\[W_n=(\mathbb Z/2)^n\rtimes S_n=(\mathbb Z/2)\wr S_n, \qquad |W_n|=2^n n!. \]

Thus `Z2 o S n` is the wreath product and `Zn · n!` is \(2^n\cdot n!\), not a product involving \(\mathbb Z^n\).

There is, however, a missing logical qualification. The trivial homomorphism exists for every surface, so a genus lower bound cannot apply to *every* homomorphism. The statement must concern an injective map, a map faithful on the finite rose stabilizer, or (as proved below) a map with infinite image. The PDF does not say whether \(S\) is closed, orientable, punctured, or has boundary, nor whether `MCG` includes orientation-reversing classes. The main result below uses the standard group \(\operatorname{Mod}(S_g)\) of orientation-preserving mapping classes of a closed connected orientable surface of genus \(g\ge2\).

A sharp free-product case of the Osin-Thom normal-rank inequality

P / partially_solved | AIM 研讨会问题汇编

It is known that for every finitely generated group we have \[\beta_1^{(2)}(\Gamma)\leq d(\Gamma)-1, \] where \(d\) stands for the minimal number of generators of \(\Gamma\). A group \(\Gamma\) is normally generated by \(S\subseteq\Gamma\) if the only normal subgroup of \(\Gamma\) containing \(S\) is \(\Gamma\) itself. Let \(nrk(\Gamma)\) be the normal rank of \(\Gamma\), i.e. the minimal number of normal generators.

Do we have \[\beta_1^{(2)}(\Gamma)\leq nrk(\Gamma)-1 \] for a torsion free group \(\Gamma\)?

来源字段：http://aimpl.org/l2invariantsgroups/3/

02726 | AIM-GEOMETRIC_GROUP_THEORY-0163

A simplexwise Patterson-Sullivan inequality and entropy-metric Hessian

P / partially_solved | AIM 研讨会问题汇编

For all T, T' in Xn as above, is it true i(T, mu of T') i(T', mu of T) >= 1? At least, where is the inequality true?

The immediately preceding paragraph in the source PDF supplies the omitted meaning of “as above”: \(T\) is a tree in Culler--Vogtmann Outer space \(X_n\), \(\mu_T\) is its Patterson--Sullivan current, and the representative of that projective current is normalized by

\[\langle T,\mu_T\rangle=1. \]

Thus the precise question is whether

\[I(T,S):=\langle S,\mu_T\rangle\langle T,\mu_S\rangle\geq 1 \tag{1.1} \]

for every \(T,S\in X_n\), and, failing that, on which pairs or subspaces it holds. I use the modern brackets \(\langle T,\nu\rangle\) for the continuous tree--current intersection form. This avoids confusing it with Guirardel's tree--tree intersection number, which is also often denoted \(i\).

The PDF was checked directly. The mathematical formulas above are present there. Most importantly, the paragraph beginning “The next question comes from Martin Lustig” and mentioning “Huber[?]” and Besson is the introduction to Problem 5.2. It is not a hypothesis or continuation of Problem 5.1. The bracketed uncertainty “Huber[?]” really occurs in the PDF and is preserved rather than silently reconstructed.

There are two common normalizations of Outer space: unit covolume and projectivized metrics. They cause no ambiguity here. If \(c>0\), then the projective Patterson--Sullivan current is unchanged on replacing \(T\) by \(cT\), while self-intersection normalization gives \(\mu_{cT}=c^{-1}\mu_T\). Consequently \(I(cT,dS)=I(T,S)\).

P / partially_solved | AIM 研讨会问题汇编

Problem 1.2. Do various candidate complexes satisfy the conditions of Problem 1.1-namely, constructing a δ-hyperbolic graph with an $\operatorname{Out}(F_n)$-action such that: (1) every irreducible-with-irreducible-powers (iwip) outer automorphism γ has positive translation distance ($|\gamma| > 0$); (2) polynomially growing γ are elliptic ($|\gamma| = 0$); (3) the construction is natural and useful; (4) the local structure permits inductive arguments; and (5) the graph is highly connected with highly connected links?

Specifically, investigate these properties for the following candidate complexes: 1. the free-factor complex; 2. the free-splitting complex (with trivial edge groups), quasi-isometric to the sphere complex; 3. variants of splitting complexes allowing non-trivial edge groups, such as splittings over $\mathbb{Z}^r$ or splittings of rank less than k; 4. a poset of commensurability classes of abelian subgroups consisting of linearly growing automorphisms; and 5. the Kapovich--Lustig graph.

Automaton Kernel Series and ℓ^2-Betti Values

P / partially_solved | Oberwolfach 报告问题汇编

Fix integers n and C, and let A be an automaton whose letters are $n\times n$ integer matrices with entries in $\{-C,-C+1,\ldots,C\}$. Say that a matrix M of dimension at least n is recognized by A if its entries vanish outside the n-neighborhood of the diagonal and A recognizes the word of consecutive $n\times n$ minors along the diagonal. Enumerate the recognized matrices as $M_1,M_2,\ldots$, and let $d(M)$ be the dimension of M. What values can $$F_A(x)=\sum_{i\geq1}\dim\ker(M_i)x^{d(M_i)}$$ take at rational x? In particular, can $F_A(q)$ be an irrational algebraic number for some automaton A and rational q?

BNS symmetry, separability, and a subgroup-tameness reduction

P / partially_solved | AIM 研讨会问题汇编

Hyperbolic case. If G is a hyperbolic free-by-cyclic group with irreducible monodromy then G is LERF if and only if the BNS invariant of every finite index subgroup of G is symmetric.

The adjacent AIM background page <http://aimpl.org/freebycyclic/6/> gives the Cayley-graph definition of the Bieri--Neumann--Strebel invariant. We write

\[S(V)=\bigl(\operatorname{Hom}(V,\mathbb R)\setminus\{0\}\bigr)/\mathbb R_{>0} \]

and interpret “symmetric” as antipodal symmetry \(\Sigma^1(V)=-\Sigma^1(V)\) in $S(V)$.

There is one important scope distinction. In current usage, an outer automorphism $\Phi\in\operatorname{Out}(F_n)$ is **irreducible** if it preserves no nontrivial free-factor system (equivalently, no free splitting of the form described by Hughes--Kudlinska). It is **fully irreducible** if every positive power is irreducible. The AIM hypothesis says irreducible, not fully irreducible. Hyperbolicity separately forces the monodromy to be atoroidal. The conditional theorem below is stated first in the fully irreducible subclass because the available subgroup-tameness conjecture has exactly that hypothesis; an explicitly analogous tameness assumption gives the same implication in the merely irreducible case.

Characteristic and generator defects in a residual p-tower

P / partially_solved | AIM 研讨会问题汇编

Let Γ be a finitely presented residually p-group. Let Γ_n be a normal p-chain with $\bigcap \Gamma_n=1$, then $$\lim \frac{b_{\mathbb Q}(\Gamma_n)}{|\Gamma:\Gamma_n|}\leq \lim \frac{b_{F_p}}{|\Gamma:\Gamma_n|}\leq \lim \frac{rk(\Gamma_n)}{|\Gamma:\Gamma_n|}.$$ Can these inequalities be strict?

The notation is repaired as follows, with every repair made explicit:

1. b_{F_p} in the middle numerator is $b_1(\Gamma_n;\mathbb F_p)$; the argument Γ_n was visibly dropped. 2. $b_{\mathbb Q}(\Gamma_n)$ is $b_1(\Gamma_n;\mathbb Q)$. 3. $rk(\Gamma_n)$ is the minimal number $d(\Gamma_n)$ of abstract generators. 4. A normal p-chain is a descending chain $\Gamma=\Gamma_0\geq \Gamma_1\geq\cdots$ of finite-index subgroups normal in Γ, with every $[\Gamma:\Gamma_n]$ a power of p (equivalently, Γ/Γ_n a finite p-group).

This reading is confirmed by the immediately preceding AIM problem 11.4, which asks about the mod-p first Betti gradient and the generator gradient, and by Ershov--Lück's definitions arising from the same workshop.

Deep fall: automatic regimes and a closed-range analytic counterexample

P / partially_solved | AIM 研讨会问题汇编

It asks for examples and nonexamples of the deep-fall property, its relation to the integral Atiyah conjecture, and analogues for nonfree ordered actions and matrices over \(\mathbb C\Gamma\).

The record needs four small but mathematically relevant corrections.

1. The paper cited as “Sumultiplicativity” and later as “Sumbmultiplicativity” is Igor Mineyev's *Submultiplicativity and the Hanna Neumann Conjecture* [Min12a]. 2. A free action and a left order on \(\Gamma\) do not by themselves produce a unique order on the cells. Mineyev chooses a fundamental domain \(\overline\Sigma_i\), orders it, identifies \(\Sigma_i=\Gamma\times\overline\Sigma_i\), and uses \[(g,\bar\sigma)<(h,\bar\tau) \quad\Longleftrightarrow\quad g<h\ \text{ or }\ (g=h\text{ and }\bar\sigma<\bar\tau). \] 3. The sets \(\mathbb E_i\) and \(\mathbb I_i\) consist of \(i\)-**cells**, not necessarily edges. “Edges” at this point of the published paper is itself a harmless dimension-one slip. 4. Mineyev introduces deep fall for a \(\Gamma\)-ordered complex of type F, meaning that \(\Gamma\backslash\widehat Y\) is finite. More generally, the formula makes analytic sense when the cellular boundary extends to a bounded map on \(\ell^2\); uniform local finiteness is a sufficient hypothesis. The AIM transcription omits this scope condition.

Let \[T=\partial_i:\ell^2(\Sigma_i)\longrightarrow \ell^2(\Sigma_{i-1}) \] be bounded, and put \(v_\sigma=T\delta_\sigma\). For \(S_{<\sigma}=\{\tau:\tau<\sigma\}\), call \(\sigma\) **order-essential** when \[v_\sigma\in M_{<\sigma}:=\overline{\operatorname{span}} \{v_\tau:\tau<\sigma\}; \] it is **order-inessential** otherwise. Write \(\mathbb E\) and \(\mathbb I\) for the two sets. Deep fall means \[v_\sigma\in \overline{\operatorname{span}} \{v_\tau:\tau<\sigma,\ \tau\in\mathbb I\} \qquad(\sigma\in\mathbb E). \tag{DF} \] The closure is taken in the codomain. The apparently counterintuitive word “essential” is faithful to Mineyev: an essential cell is the one whose boundary is already in the closed span of earlier boundaries.

Directed axes, power minsets, and the shortcut defect in Lipschitz Outer space

P / partially_solved | AIM 研讨会问题汇编

This is Problem 2.1 in the AIM workshop notes *The geometry of the outer automorphism group of a free group* (25--29 October 2010, edited by Johanna Mangahas). In normalized notation, it asks for analogies between Teichmüller/Weil--Petersson geodesics and geodesics in Culler--Vogtmann Outer space with the Lipschitz metric:

1. Which geodesics or lines have strongly contracting projection maps? 2. Is there a useful “thick part”? 3. How does geodesic behavior relate to boundary theory? 4. For an iwip \(\phi\), describe \[\operatorname{Min}(\phi)= \left\{X:d(X,\phi X)=\inf_Y d(Y,\phi Y)\right\}. \] Is it CAT(0), contained in a CAT(0) space, an axis bundle, or quasi-isometric to a line? 5. How close are \(\operatorname{Min}(\phi)\) and \(\operatorname{Min}(\phi^{-1})\)?

The discussion asks in addition whether thick geodesics are contracting, whether iwip axes are quantitatively thick, whether taking powers changes the minset, and how train-track points and axis bundles enter.

The all-caps line `THE GEOMETRY ... 3` is a running page header. The final `3. GROUP PROPERTIES` is the heading of the next section and is not part of Problem 2.1.

The metric belongs to Outer space \(CV_n\), not to \(\operatorname{Out}(F_n)\) itself. The group acts on \(CV_n\) by isometries. Crucially, the Lipschitz metric is asymmetric, so every claim below records its direction.

Explicit outer automorphisms for a RAAG join family and a free-product obstruction

P / partially_solved | AIM 研讨会问题汇编

For an Artin group \(A\), when is \(\operatorname{Out}(A)\) finite/finitely generated? Find explicit generators.

The record itself contains no qualifications on the Coxeter matrix. Thus it is a programmatic question about all finite-rank Artin groups, not a single yes/no conjecture. No corruption or ambiguity is visible in the source record. Throughout, an Artin group is assumed to have a finite standard generating set.

This report separates three logically different requests:

1. decide when \(\operatorname{Out}(A)\) is finite; 2. decide when it is finitely generated (or finitely presented); 3. give abstract group generators, which may be strictly more numerous than graph symmetries of a chosen Artin presentation.

The strongest new work in this attempt is a complete, elementary outer-automorphism calculation for a two-parameter family of right-angled Artin groups and a free-product obstruction to finiteness.

03128 | KOU-10.32

Kourovka Notebook Problem 10.32

O / open | Kourovka 群论问题集

A group word is said to be *universal on a group* G if its values on G run over the whole of G. For an arbitrary constant $c > 8/5$, J. L. Brenner, R. J. Evans, and D. M. Silberger (*Proc. Amer. Math. Soc.*, **96**, no. 1 (1986), 23--28) proved that there exists a number $N_0=N_0(c)$ such that the word x^ry^s, $rs \ne 0$, is universal on the alternating group ${\mathbb{A}_n$ for any $ n \geq \max \{ N_0, \; c\cdot \log m(r,s)\} $, where $m(r,s)$ is the product of all primes dividing rs if $r,s \not\in \{ -1, 1\} $, and $m(r,s)=1$ if $r,s \in \{ -1, 1\} $. For example, one can take $ N_0(5/2)=5$ and $ N_0(2)=29$. Find an analogous bound for the degree of the symmetric group ${\mathbb{S}_n$ under hypothesis that at least one of the r, s is odd: up to now, here only a more crude bound $ n \geq \max \{ 6, \; 4m(r,s) - 4\} $ is known (M. Droste, *Proc. Amer. Math. Soc.*, **96**, no. 1 (1986), 18--22).

Is it true that $SL_n({\mathbb{Z}[x_1,\ldots ,x_r])$, for n sufficiently large, is a group of type $(FP)_m$ (which is defined in the same way as $(FP)_{\infty}$ was defined in 6.3, but with that weakening that the condition of being finitely generated is not imposed on the terms of the resolution with numbers $ > m$). An affirmative answer is known for $m=0$, $n \geq 3$ (A. A. Suslin, *Math. USSR Izvestiya*, **11** (1977), 221--238) and for $m=1$, $n \geq 5$ (M. S. Tulenbayev, *Math. USSR Sbornik*, **45** (1983), 139--154; \ U. Rehmann, C. Soul\'e, in: *Algebraic K-theory, Proc. Conf., Northwestern Univ., Evanston, Ill., 1976, $($Lect. Notes Math.*, **551**), Springer, Berlin, 1976, 164--169).

(H. Bass). Let G be a group, e an idempotent matrix over ${\mathbb{Z}G$ and let $\mathrm{tr} e=\sum\limits_{g\in G}e_gg, e_g \in {\mathbb{Z}.$ *Strong conjecture:* for any non-trivial $x \in G$, the equation $\sum\limits_{g\sim x} e_g=0$ holds where $\sim $ denotes conjugacy in G. *Weak conjecture:* $\sum\limits_{g\in G} e_g=0$. The strong conjecture has been proved for finite, abelian and linear groups and the weak conjecture has been proved for residually finite groups.

H. Bass' Comment of 2005: Significant progress has been made; a good up-to-date account is in the paper (A. J. Berrick, I. Chatterji, G. Mislin, *Math. Ann.*, **329** (2004), 597--621).

03187 | KOU-11.104

Kourovka Notebook Problem 11.104

S / solved | Kourovka 群论问题集

Let G be a finite group of order $p^a\cdot q^b\cdots $, where $p, q, \ldots $ are distinct primes. Introduce distinct variables $x_p, x_q, \ldots $ corresponding to $p, q, \ldots $. Define functions f, φ from the lattice of subgroups of G to the polynomial ring ${\mathbb{Z}[x_p,x_q,\ldots]$ as follows:

(1) if H has order $p^{\alpha}\cdot q^{\beta }\cdots $, then $f(H)=x_p^{\alpha}\cdot x_q^{\beta}\cdots $;

(2) for all $H \leq G$, we have $\sum\limits_{K\leq H}\varphi (K)=f(H)$.

Then $f(G), \varphi (G)$ may be called the *order* and *Eulerian polynomials* of G. Substituting $p^m, q^m, \ldots $ for $x_p, x_q, \ldots $ in these polynomials we get the mth power of the order of G and the number of ordered m-tuples of elements that generate G respectively.

It is known that if G is $p $-solvable, then $\varphi (G)$ is a product of a polynomial in x_p and a polynomial in the remaining variables. Consequently, if G is solvable, $\varphi (G)$ is the product of a polynomial in x_p by a polynomial in x_q by $\ldots $. Are the converses of these statements true \ a) for solvable groups? \ b) for $p $-solvable groups?

Kourovka Notebook Problem 11.29

P / partially_solved | Kourovka 群论问题集

Let F be a free group and ${\mathfrak{f}}={\mathbb{Z}F(F - 1)$ the augmentation ideal of the integral group ring ${\mathbb{Z}F$. For any normal subgroup R of F define the corresponding ideal ${\mathfrak{r}}={\mathbb{Z}F(R - 1)= _{\mathrm{id}}} (r - 1\mid r \in R)$. One may identify, for instance, $F \cap (1 + {\mathfrak{r}} {\mathfrak{f}})=R'$, where F is naturally imbedded into ${\mathbb{Z}F$ and $1 + {\mathfrak{r}} {\mathfrak{f}}=\{ 1 + a\mid a \in {\mathfrak{r}}{\mathfrak{f}}\} $.

Identify in an analogous way in terms of corresponding subgroups of F

a) $F \cap (1 + {\mathfrak{r}}_1 {\mathfrak{r}_2}\cdot \cdot \cdot {\mathfrak{r}}_n)$, where R_i are normal subgroups of F, $i=1, 2,\ldots ,n$;

b) $F \cap (1 + {\mathfrak{r}}_1{\mathfrak{r}}_2{\mathfrak{r}}_3)$;

c) $F \cap (1 + {\mathfrak{f}} {\mathfrak{s}} + {\mathfrak{f}}^n)$, where F/S is finitely generated nilpotent;

d) $F \cap (1 + {\mathfrak{f}}{\mathfrak{s}}{\mathfrak{f}} + {\mathfrak{f}}^n)$;

e) $F \cap (1 + {\mathfrak{r}}(k) + {\mathfrak{f}}^n)$, $n > k \geq 2$, where ${\mathfrak{r}}(k)={\mathfrak{r}}{\mathfrak{f}}^{k-1} + {\mathfrak{f}}{\mathfrak{r}} {\mathfrak{f}}^{k-2} + \cdots + {\mathfrak{f}}^{k-1}{\mathfrak{r}}$.

[Archived solved part(s) of 11.29:] f) Let F be a free group and ${\mathfrak{f}}={\mathbb{Z}F(F - 1)$ the augmentation ideal of the integral group ring ${\mathbb{Z}F$. For any normal subgroup R of F define the corresponding ideal ${\mathfrak{r}}={\mathbb{Z}F(R - 1)= _{\mathrm{id}}} (r - 1\mid r \in R)$. One may identify, for instance, $F \cap (1 + {\mathfrak{r}} {\mathfrak{f}})=R'$, where F is naturally imbedded into ${\mathbb{Z}F$ and $1 + {\mathfrak{r}} {\mathfrak{f}}=\{ 1 + a\mid a \in {\mathfrak{r}}{\mathfrak{f}}\} $. Is the quotient group $(F \cap (1 + {\mathfrak{r}} + {\mathfrak{f}}^n))/R\cdot \gamma _n(F)$ always abelian?

A t-(v,k,λ) *design* ${\mathcal{D}}=(X,{\mathcal{B}})$ contains a set X of v points and a set ${\mathcal{B}}$ of k-element subsets of X called *blocks* such that each t-element subset of X is contained in λ blocks. Prove that there are no nontrivial block-transitive 6-designs. (We have shown that there are no nontrivial block-transitive 8-designs and there are certainly some block-transitive, even flag-transitive, 5-designs.)

Comment of 2009: In (*Finite Geometry and Combinatorics (Deinze 1992)*, Cambridge Univ. Press, 1993, 103--119) we showed that a block-transitive group G on a nontrivial 6-design is either an affine group $AGL(d,2)$ or is between $PSL(2,q)$ and $P\Gamma L(2,q)$; in (M. Huber, *J. Combin. Theory Ser. A*, **117**, no. 2 (2010), 196--203) it is shown that for the case $\lambda=1$ the group G may only be $P\Gamma L(2,p^e)$, where p is 2 or 3 and e is an odd prime power. *Comment of 2013:* In the case $\lambda=1$ there are no block-transitive 7-designs (M. Huber, *Discrete Math. Theor. Comput. Sci.*, **12**, no. 1 (2010), 123--132). *Comment of 2021:* There are no nontrivial 6-designs with $k\leq 10^4$ in the case where the automorphism group is almost simple (Q. Tan, W. Liu, J. Chen, *Algebra Colloq.*, **21**, no. 2 (2014), 231--234).

A group G acting on a set Ω will be said to be {\it \mathrm{1}-$\{ 2\}$-transitive} if it acts transitively on the set $ \Omega ^{1,\{ 2\}}=\{ (\alpha , \{ \beta ,\gamma \})\mid \alpha ,\beta ,\gamma \mbox{ distinct}\} .$ Thus G is 1-$\{ 2\}$-transitive if and only if it is transitive and a stabilizer G_{α} is 2-homogeneous on $\Omega \setminus \{ \alpha \} $. The problem is to classify all (infinite) permutation groups that are 1-$\{ 2\}$-transitive but not 3-transitive.

03277 | KOU-11.71

Kourovka Notebook Problem 11.71

O / open | Kourovka 群论问题集

Let A be a finite group with a normal subgroup H. A subgroup U of H is called an *A-covering subgroup* of H if $\bigcup\limits_{a\in A} U^a=H$. Is there a function $f\!: {\mathbb{N} \rightarrow {\mathbb{N}$ such that whenever $U< H < A$, where A is a finite group, H is a normal subgroup of $ A$ of index n, and U is an A-covering subgroup of H, the index $|H:U| \leq f(n)$? (We have shown that the answer is ``yes'' if U is a maximal subgroup of H.)

Comments of 2025: The conjecture is proved in the case where H acts innately transitively on the coset space $[H:U]$ (M. Fusari, A. Previtali, P. Spiga, *J. Group Theory*, **27** (2024), 929--965); \ for $n=3$ with $|H:U|\leq 10$ (L. Gogniat, P. Spiga, *Preprint*, 2025, https://arxiv.org/abs/2502.01287); and if $H=UL$ where L is a minimal A-invariant subgroup of H (M. Fusari, S. Harper, P. Spiga, *Bull. Austral. Math. Soc.*, 2025, https://doi.org/10.1017/S0004972725000176).

03287 | KOU-11.80

Kourovka Notebook Problem 11.80

O / open | Kourovka 群论问题集

Let G be a primitive permutation group on a finite set Ω and suppose that, for $\alpha \in \Omega $, G_{α} acts 2-transitively on one of its orbits in $\Omega \setminus \{ \alpha \} $. By (C. E. Praeger, *J. Austral. Math. Soc. (A)*, **45**, 1988, 66--77) either

(a) $T \leq G \leq \mathrm{Aut} T$ for some nonabelian simple group T, or

(b) G has a unique minimal normal subgroup which is regular on Ω.

For what classes of simple groups in (a) is a classification feasible? Describe the examples in as explicit a manner as possible. Classify all groups in (b).

Remark of 1999: Two papers by X. G. Fang and C. E. Praeger (*Commun. Algebra*, **27** (1999), 3727--3754 and 3755--3769) show that this is feasible for T a Suzuki and Ree simple group, and a paper of J. Wang and C. E. Praeger (*J. Algebra*, **180** (1996), 808--833) suggests that this may not be the case for T an alternating group. *Remark of 2001:* In (X. G. Fang, G. Havas, J. Wang, *European J. Combin.*, **20**, no. 6 (1999), 551--557) new examples are constructed with $G=PSU(3,q)$. *Remark of 2009:* It was shown in (D. Leemans, *J. Algebra*, **322**, no. 3 (2009), 882--892) that for part (a) classification is feasible for self-paired 2-transitive suborbits with T a sporadic simple group; in this case these suborbits correspond to 2-arc-transitive actions on undirected graphs.

Kourovka Notebook Problem 12.23

O / open | Kourovka 群论问题集

The *index of permutability* of a group G is defined to be the minimal integer $k \geq 2$ such that for each $k $-tuple $x_1,\ldots ,x_k$ of elements in G there is a non-identity permutation σ on k symbols such that $x_1\cdots x_k=x_{\sigma (1)}\cdots x_{\sigma (k)}$. Determine the index of permutability of the symmetric group ${\mathbb{S}_n$.

Given a ring R with identity, the automorphisms of $R[[x]]$ sending x to $x\left(1 + \sum_{i=1}^{\infty} a_ix^i\right) $, $a_i\in R$, form a group $N(R)$. We know that $N({\mathbb{Z})$ contains a copy of the free group F_2 of rank 2 and, from work of A. Weiss, that $N({\mathbb{Z}/p{\mathbb{Z})$ contains a copy of every finite $p $-group (but not of ${\mathbb{Z}_{p^{\infty}})$, p a prime. Does $N({\mathbb{Z}/p{\mathbb{Z})$ contain a copy of F_2?

Kourovka Notebook Problem 12.27

O / open | Kourovka 群论问题集

Let G be a simple locally finite group. We say that G is a *group of finite type* if there is a non-trivial permutational representation of G such that some finite subgroup of G has no regular orbits. Investigate and, perhaps, classify the simple locally finite groups of finite type. Partial results see in (B. Hartley, A. Zalesski, *Isr. J. Math.*, **82** (1993), 299--327, *J. London Math. Soc.*, **55** (1997), 210--230; \ F. Leinen, O. Puglisi, *Illinois J. Math.*, **47** (2003), 345--360).

03330 | KOU-12.28

Kourovka Notebook Problem 12.28

O / open | Kourovka 群论问题集

Let G be a group. A function $f\! : G \rightarrow {\mathbb{C}}$ is called \begin{enumerate}

\item[1)] *normed* if $f(1)=1$;

\item[2)] *central* if $f(gh)=f(hg)$ for all $g,h \in G$;

\item[3)] *positive-definite* if $\sum\limits_{k, l}f(g_k^{-1}g_l) \overline{\! c}_kc_l \geq 0$ for any $g_1,\ldots ,g_n \in G$ and any $c_1,\ldots ,c_n \in {\mathbb{C}}$. \end{enumerate}

Classify the infinite simple locally finite groups G which possess functions satisfying 1)--3). The simple Chevalley groups are known to have no such functions, while such functions exist on locally matrix (or stable) classical groups over finite fields. The question is motivated by the theory of $C^{\displaystyle{*}} $-algebras, see $\S$ 9 in (A. M. Vershik, S. V. Kerov, *J. Sov. Math.*, **38** (1987), 1701--1733). Partial results see in (F. Leinen, O. Puglisi, *J. Pure Appl. Algebra*, **208** (2007), 1003--1021, *J. London Math. Soc.*, **70** (2004), 678--690).

Kourovka Notebook Problem 14.104

S / solved | Kourovka 群论问题集

An infinite group G is called a *monster of the first kind* if it has elements of order > 2 and for any such an element a and for any proper subgroup H of G, there is an element g in $G\setminus H$, such that $\left< a, a^g\right> =G$. A. Yu. Olshanskii showed that there are continuously many monsters of the first kind (see Archive, 6.63). Does there exist, for any such a monster, a torsion-free group which is a central extension of a cyclic group by the given monster?

问题集入口：https://kourovkanotebookorg.wordpress.com/

03518 | KOU-14.46

Kourovka Notebook Problem 14.46

O / open | Kourovka 群论问题集

A finite group G is said to be *almost simple* if $T\leq G\leq \mathrm{Aut}(T)$ for some nonabelian simple group T. By definition, a *finite linear space* consists of a set V of points, together with a collection of k-element subsets of V, called *lines* ($k\geq 3$), such that every pair of points is contained in exactly one line. Classify the finite linear spaces which admit a line-transitive almost simple subgroup G of automorphisms which acts transitively on points.

A. Camina, P. Neumann and C. E. Praeger have solved this problem in the case where T is an alternating group. In (A. Camina, C. E. Praeger, *Aequat. Math.*, **61** (2001), 221--232) it is shown that a line-transitive group of automorphisms of a finite linear space which is point-*quasiprimitive* (i. e. all of whose non-trivial normal subgroups are point-transitive) is almost simple or affine. \

Remarks of 2005: \ The cases of the following groups, but not almost simple groups with this socle, were dealt with: $PSU(3,q)$ (W. Liu, *Linear Algebra Appl.*, **374** (2003), 291--305); $PSL(2,q)$ (W. Liu, *J. Combin. Theory (A)*, **103** (2003), 209--222); $Sz(q)$ (W. Liu, *Discrete Math.*, **269** (2003), 181--190); $Ree(q)$ (W. Liu, *Europ. J. Combin.*, **25** (2004), 311--325); sporadic simple groups were done in (A. R. Camina, F. Spiezia, *J. Combin. Des.*, **8** (2000), 353--362). \ *Remark of 2009:* It was shown (N. Gill, *Trans. Amer. Math. Soc.*, **368** (2016), 3017--3057) that for non-desarguesian projective planes a point-quasiprimitive group would be affine. \ *Remark of 2013:* The problem is solved for large-dimensional classical groups (A. Camina, N. Gill, A. E. Zalesski, *Bull. Belg. Math. Soc. Simon Stevin*, **15**, no. 4 (2008), 705--731).

Kourovka Notebook Problem 14.5

P / partially_solved | Kourovka 群论问题集

Let G be an infinite group admitting non-discrete Hausdorff group topologies, and ${\mathcal{L}}(G)$ the lattice of all group topologies on G.

a) Is it true that for any natural number k there exists a non-refinable chain $\tau_0 < \tau_1<\cdots < \tau_k$ of length k of Hausdorff topologies in ${\mathcal{L}}(G)$? (For countable nilpotent groups this is true (A. G. Topale, *Deposited in VINITI*, 25.12.98, no. 3849--V 98 (Russian)).)

b) Let k,m,n be natural numbers and let G be a nilpotent group of class k. Suppose that $\tau_0 <\tau_1 <\cdots < \tau_m$ and $\tau'_0 <\tau'_1 <\cdots < \tau'_n$ are non-refinable chains of Hausdorff topologies in ${\mathcal{L}}(G)$ such that $\tau_0 =\tau'_0$ and $\tau_m =\tau'_n$. Is it true that $m\leq n\cdot k$ and this inequality is best-possible? (This is true if $k=1$, since for G abelian the lattice ${\mathcal{L}}(G)$ is modular.)

c) Is it true that there exists a countable G such that in the lattice ${\mathcal{L}}(G)$ there are a finite non-refinable chain $\tau_0 <\tau_1 <\cdots < \tau_k$ of Hausdorff topologies and an infinite chain $\{\tau'_{\gamma}\mid \gamma\in\Gamma\}$ of topologies such that $\tau_0<\tau'_{\gamma} < \tau_k$ for any $\gamma\in\Gamma$?

d) Let G be an abelian group, k a natural number. Let A_k be the set of all those Hausdorff group topologies on G that, for every topology $\tau\in A_k$, any non-refinable chain of topologies starting from τ and terminating at the discrete topology has length k. Is it true that $A_k\bigcap \{\tau'_{\gamma}\mid \gamma\in\Gamma \}\neq\varnothing$ for any infinite non-refinable chain $\{\tau'_{\gamma}\mid \gamma\in\Gamma \}$ of Hausdorff topologies containing the discrete topology? (This is true for $k=1$.)

Conjecture: Let G be a profinite group such that the set of solutions of the equation $x^n=1$ has positive Haar measure. Then G has an open subgroup H and an element t such that all elements of the coset tH have order dividing n.

This is true in the case $n=2$. It would be interesting to see whether similar results hold for profinite groups in which the set of solutions of some equation has positive measure.

Comment of 2021: This is also proved for $n=3$ (A. Abdollahi, M. S. Malekan, *Adv. Group Theory Appl.*, **13** (2022), 71--81). *Comment of 2025*: Significant progress was obtained in (S. Kionke, N. Otmen, T. Toti, M. Vannacci, T. Weigel, *Preprint*, 2025, https://arxiv.org/pdf/2507.19086).

03533 | KOU-14.6

Kourovka Notebook Problem 14.6

O / open | Kourovka 群论问题集

A group Γ is said to have {\it Property $P_{\rm{nai}}$} if, for any finite subset F of $\Gamma \setminus \{1\},$ there exists an element $y_0 \in \Gamma$ of infinite order such that, for each $x \in F$, the canonical epimorphism from the free product $\langle x \rangle * \langle y_0\rangle$ onto the subgroup $\langle x , y_0 \rangle$ of Γ generated by x and y_0 is an isomorphism. For $n \in \{2, 3,\ldots\},$ does $PSL_n({\mathbb{Z})$ have Property $P_{\rm{nai}}$? More generally, if Γ is a lattice in a connected real Lie group G which is simple and with centre reduced to $\{ 1\},$ does Γ have Property $P_{\rm{nai}}$?

Answers are known to be " yes" \ if $n = 2$, and more generally if G has real rank 1 (M. Bekka, M. Cowling, P. de la Harpe, *Publ. Math. IHES*, **80** (1994), 117--134).

Comments of 2018: Property $P_{\rm{nai}}$ has been established for relatively hyperbolic groups (G. Arzhantseva, A. Minasyan, *J. Funct. Anal.*, **243**, no. 1 (2007), 345--351) and for groups acting on CAT(0) cube complexes with appropriate conditions (A. Kar, M. Sageev, *Comment. Math. Helv.*, **91** (2016), 543--561). Some progress has been made in the preprint (T. Poznansky, http://arxiv.org/abs/0812.2486).

Let Γ_g be the fundamental group of a closed surface of genus $g \geq 2.$ For each finite system S of generators of $\Gamma_g,$ let $\beta_S(n)$ denote the number of elements of $\Gamma _g$ which can be written as products of at most n elements of $S \cup S^{-1},$ and let $\omega (\Gamma _g,S) = \limsup_{n \to \infty}\root n \of {\beta _S(n)}$ be the growth rate of the sequence $\left(\beta _S(n) \right)_{n \geq 0}.$ Compute the infimum $\omega(\Gamma _g)$ of the $\omega (\Gamma _g,S)$ over all finite sets of generators of $\Gamma _g.$

It is easy to see that, for a free group F_k of rank $k \geq 2,$ the corresponding infimum is $\omega(F_k) = 2k-1$ (M. Gromov, *Structures m\'etriques pour les vari\'et\'es riemanniennes,* Cedic/F. Nathan, Paris, 1981, Ex. 5.13). As any generating set of Γ_g contains a subset of $2g-1$ elements generating a subgroup of infinite index in Γ_g with abelianization ${\mathbb{Z} ^{2g-1},$ hence a subgroup which is free of rank $2g-1,$ it follows that $\omega(\Gamma_g) \geq 4g-3.$

Kourovka Notebook Problem 14.71

S / solved | Kourovka 群论问题集

Consider a free group F of finite rank and an arbitrary group G. Define the *G-closure* $\mathrm{cl}_G(T)$ of any subset $T\subseteq F$ as the intersection of the kernels of all those homomorphisms $\mu:F \rightarrow G$ of F into G that vanish on T: \ $ \mathrm{cl}_G(T) = \bigcap \{ \mathrm{Ker} \mu \mid \mu :F \rightarrow G;\; T\subseteq \mathrm{Ker} \mu \}$. \ Groups G and H are called *geometrically equivalent* if for every free group F and every subset $T\subset F$ the G- and H-closures of T coincide: $\mathrm{cl}_G(T)=\mathrm{cl}_H(T)$. It is easy to see that if G and H are geometrically equivalent then they have the same quasiidentities. Is it true that if two groups have the same quasiidentities then they are geometrically equivalent? This is true for nilpotent groups.

Conjecture: There is a function f on the natural numbers such that, if Γ is a finite, vertex-transitive, locally-quasiprimitive graph of valency v, then the number of automorphisms fixing a given vertex is at most $f(v)$. (By definition, a vertex-transitive graph Γ is *locally-quasiprimitive* if the stabilizer in $Aut(\Gamma)$ of a vertex α is quasiprimitive (see 14.46) in its action on the set of vertices adjacent to α.)

To prove the conjecture above one need only consider the case where $Aut(\Gamma)$ has the property that every non-trivial normal subgroup has at most two orbits on vertices (C. E. Praeger, *Ars Combin.*, **19 A** (1985), 149--163). The analogous conjecture for finite, vertex-transitive, locally-primitive graphs was made by R. Weiss in 1978 and is still open. For non-bipartite graphs, there is a ``reduction'' of Weiss' conjecture to the case where the automorphism group is almost simple (see 14.46 for definition) (M. Conder, C. H. Li, C. E. Praeger, *Proc. Edinburgh Math. Soc. (2)*, **43**, no. 1 (2000), 129--138).

Comment of 2013: These conjectures have been proved in the case where there is an upper bound on the degree of any alternating group occurring as a quotient of a subgroup (C. E. Praeger, L. Pyber, P. Spiga, E. Szab\'{o}, *Proc. Amer. Math. Soc.*, **140**, no. 7 (2012), 2307--2318). *Comment of 2021:* This has been proved in the case where the group induced on the neighbourhood of a vertex has an abelian regular normal subgroup (P. Spiga, *Bull. London Math. Soc.*, **48**, no. 1 (2016), 12--18.)

Kourovka Notebook Problem 14.89

O / open | Kourovka 群论问题集

(E. A. O'Brien, A. Shalev). Let P be a finite p-group of order p^m and let $m=2n+e$ with $e=0$ or 1. By a theorem of P. Hall the number of conjugacy classes of P has the form $n(p^2-1) + p^e + a(p^2-1)(p-1)$ for some integer $a\geq 0$, which is called the *abundance* of P.

a) Is there a bound for the coclass of P which depends only on a? Note that $a=0$ implies coclass 1 and that all known examples with $a=1$ have coclass ≤ 3. (The group P has *coclass* r if $|P|=p^{c+r}$ where c is the nilpotency class of P.)

b) Is there an element $s\in P$ such that $|C_P(s)|\le p^{f(a)}$ for some $f(a)$ depending only on a? We already know that we can take $f(0)=2$ and it seems that $f(1)=3$.

Note that A. Jaikin-Zapirain (*J. Group Theory*, **3**, no. 3 (2000), 225--231) has proved that $|P|\le p^{f(p,a)}$ for some function f of p and a only.

Kourovka Notebook Problem 15.19

P / partially_solved | Kourovka 群论问题集

Let p be a prime, and ${\mathcal{F}}_p$ the class of finitely generated groups acting faithfully on a p-regular rooted tree by finite automata. Any group in ${\mathcal{F}}_p$ is residually-p (residually in the class of finite p-groups) and has word problem that is solvable in (at worst) exponential time. There exist therefore groups that are residually-p, have a solvable word problem, and do not belong to ${\mathcal{F}}_p$; though no concrete example is known. For instance:

a) Is it true that some (or even all) the groups given in (R. I. Grigorchuk, *Math. USSR--Sb.*, **54** (1986), 185--205) do not belong to ${\mathcal{F}}_p$ when the sequence ω is computable, but not periodic?

b) Does ${\mathbb{Z}\wr({\mathbb{Z}\wr {\mathbb{Z}})$ belong to ${\mathcal{F}}_2$? (Here the wreath products are restricted.)

See (A. M. Brunner, S. Sidki, *J. Algebra*, **257** (2002), 51--64) and (R. I. Grigorchuk, V. V. Nekrashevich, V. I. Sushchanskiĭ, *in: Dynamical systems, automata, and infinite groups. Proc. Steklov Inst. Math.*, **231** (2000), 128--203).

Kourovka Notebook Problem 15.2

O / open | Kourovka 群论问题集

By a theorem of W. Burnside, if $\chi \in \mathrm{Irr}(G)$ and $\chi(1) > 1$, then there exists $x \in G$ such that $\chi(x) = 0$, that is, only the linear characters are ``nonvanishing''. It is interesting to consider the dual notion of *nonvanishing elements* of a finite group G, that is, the elements $x \in G$ such that $\chi(x) \ne 0$ for all $\chi \in \mathrm{Irr}(G)$.

a) It is proved (I. M. Isaacs, G. Navarro, T. R. Wolf, *J. Algebra*, **222**, no. 2 (1999), 413--423) that if G is solvable and $x \in G$ is a nonvanishing element of odd order, then x belongs to the Fitting subgroup $**F**(G)$. Is this true for elements of even order too? (M. Miyamoto showed in 2008 that every nontrivial abelian normal subgroup of a finite group contains a nonvanishing element.)

b) Which nonabelian simple groups have nonidentity nonvanishing elements? (For example, ${\mathbb{A}_7$ has.)

03613 | KOU-15.39

Kourovka Notebook Problem 15.39

S / solved | Kourovka 群论问题集

Axiomatizing the basic properties of subnormal subgroups, we say that a functor τ associating with every finite group G some non-empty set $\tau (G) $ of its subgroups is an *ETP-functor* if

1) $ \tau (A) ^ {\varphi} \subseteq \tau (B) $ and $\tau (B) ^ {\varphi^ {-1}} \subseteq\tau (A) $ for any epimorphism $\varphi : A\longmapsto B$, as well as $\{ H\cap R\mid R\in\tau (G) \} \subseteq\tau (H) $ for any subgroup $H\leq G$;

2) $\tau (H) \subseteq\tau (G) $ for any subgroup $H\in\tau (G) $;

3) $\tau (G) $ is a sublattice of the lattice of all subgroups of G.

Let τ be an ETP-functor. Does there exist a hereditary formation $\mathfrak {F} $ such that $\tau (G) $ coincides with the set of all $\mathfrak {F} $-subnormal subgroups in any finite group G? This is true for finite soluble groups (A. F. Vasil'ev, S. F. Kamornikov, *Siberian Math. J.*, **42**, no. 1 (2001), 25--33).

Kourovka Notebook Problem 15.4

S / solved | Kourovka 群论问题集

Is it true that large growth implies non-amenability? More precisely, consider a number $\epsilon > 0$, an integer $k \geq 2$, a group Γ generated by a set S of k elements, and the corresponding exponential growth rate $\omega(\Gamma,S)$ defined as in 14.7. For ϵ small enough, does the inequality \ $\omega(\Gamma,S) \geq 2k-1-\epsilon$ \ imply that Γ is non-amenable?

If $\omega(\Gamma,S) = 2k-1$, it is easy to show that Γ is free on S, and in particular non-amenable; see Section 2 in (R. I. Grigorchuk, P. de la Harpe, *J. Dynam. Control Syst.*, **3**, no. 1 (1997), 51--89).

Kourovka Notebook Problem 15.41

O / open | Kourovka 群论问题集

Let $R(m,p)$ denote the largest finite m-generator group of prime exponent p.

a) Can the nilpotency class of $R(m,p)$ be bounded by a polynomial in m? (This is true for $p=2, 3, 5, 7$.)

b) Can the nilpotency class of $R(m,p)$ be bounded by a linear function in m? (This is true for $p=2, 3, 5$.)

c) In particular, can the nilpotency class of $R(m,7)$ be bounded by a linear function in m?

My guess is ``no'' to the first two questions for general $p$, but ``yes'' to the third. By contrast, a beautiful and simple argument of Mike Newman shows that if $m\geq 2$ and $k\geq 2$ ($k\geq 3$ for $p=2$), then the order of $R(m,p^k)$ is at least $p^{p^{.^{.^{.^{p^m}}}}}$, with p appearing k times in the tower; see (M. Vaughan-Lee, E. I. Zelmanov, *J. Austral. Math. Soc. (A)*, **67**, no. 2 (1999), 261--271).

03617 | KOU-15.42

Kourovka Notebook Problem 15.42

O / open | Kourovka 群论问题集

Is it true that the group algebra $k[F]$ of R. Thompson's group F (see 12.20) over a field k satisfies the Ore condition, that is, for any $a,b \in k[F]$ there exist $u,v \in k[F]$ such that $au=bv$ and either u or v is nonzero? If the answer is negative, then F is not amenable.

Comment of 2026: If the answer is positive, then F is amenable (so problem 15.42 is equivalent to 12.20), because the ``if and only if'' statement holds for groups satisfying Kaplansky's zero-divisor conjecture (D. Kielak, *Prepint*, 2026, https://arxiv.org/pdf/1605.09133v2), and F does satisfy it.

Kourovka Notebook Problem 15.45

P / partially_solved | Kourovka 群论问题集

We define the class of *hierarchically decomposable* groups in the following way. First, if ${\mathfrak{X}}$ is any class of groups, then let $**H**_1{\mathfrak{X}}$ denote the class of groups which admit an admissible action on a finite-dimensional contractible complex in such a way that every cell stabilizer belongs to ${\mathfrak{X}}$. Then the ``big'' class $**H**{\mathfrak{X}}$ is defined to be the smallest $**H**_1$-closed class containing ${\mathfrak{X}}$.

a) Let ${\mathfrak{F}}$ be the class of all finite groups. Find an example of an $**H**{\mathfrak{F}}$ group which is not in $**H**_3{\mathfrak{F}}$ $(=**H**_1**H**_1**H**_1F)$.

b) Prove or disprove that there is an ordinal α such that $**H**_{\alpha}{\mathfrak{F}}=**H**{\mathfrak{F}}$, where $**H**_{\alpha}$ is the operator on classes of groups defined by transfinite induction in the obvious way starting from $**H**_1$. \ *Editor's comment*: It is proved that such an ordinal cannot be countable (T. Januszkiewicz, P. H. Kropholler, I. J. Leary, *Bull. London Math. Soc.*, **42**, No. 5 (2010), 896--904).

Kourovka Notebook Problem 15.66

O / open | Kourovka 群论问题集

For a class $\mathfrak{X}$ of groups let $g_{\mathfrak{X}}(n)$ be the number of groups of order n in the class $\mathfrak{X}$ (up to isomorphism). Many years ago I formulated the following problem: find good upper bounds for the quotient $g_{\mathfrak{V}}(n)/g_{\mathfrak{U}}(n)$, where $\mathfrak{V}$ is a variety that is defined by its finite groups and $\mathfrak{U}$ is a subvariety of $\mathfrak{V}$. (This quotient is not defined for all n but only for those for which there are groups of order n in $\mathfrak{U}$.) Some progress has been made by G. Venkataraman (*Quart. J. Math. Oxford (2)*, **48**, no. 189 (1997), 107--125) when $\mathfrak{V}$ is a variety generated by finite groups all of whose Sylow subgroups are abelian. *Conjecture:* if $\mathfrak{V}$ is a locally finite variety of $p $-groups and $\mathfrak{U}$ is a non-abelian subvariety of ${\mathfrak{V}}$, then $g_{\mathfrak{V}}(p^m)/g_{\mathfrak{U}}(p^m) < p^{O(m^2)}$.

Moreover, this seems a possible way to attack the Sims Conjecture that when we write the number of groups of order p^m as $p^{{2\over27}m^3 + \varepsilon(m)}$ the error term $\varepsilon(m)$ is $O(m^2)$.

More precisely, suppose that P is a 2-generator finite $p $-group whose lower central quotients $\gamma _i(P)/\gamma _{i+1}(P)$ are cyclic for all $i\geq 2$. Is it true that P contains a normal subgroup N of nilpotency class ≤ 2 such that the rank of P/N is bounded in terms of p only?

问题集入口：https://kourovkanotebookorg.wordpress.com/

03686 | KOU-16.104

Kourovka Notebook Problem 16.104

S / solved | Kourovka 群论问题集

If \(G \) is a finite group, then every element \(a \) of the rational group algebra \({\mathbb{Q}}[G] \) has a unique Jordan decomposition \(a =a _{s}+a _{n} \), where \(a _{n}\in {\mathbb{Q}}[G] \) is nilpotent, \(a _{s}\in {\mathbb{Q}}[G] \) is semisimple over \(\mathbb{Q} \), and \(a _{s}a _{n}=a _{n}a _{s} \). The integral group ring \({\mathbb{Z}}[G] \) is said to have the *additive Jordan decomposition* property (AJD) if \(a _{s}, a _{n} \in {\mathbb{Z}}[G] \) for every \(a \in {\mathbb{Z}}[G] \). If \(a \in {\mathbb{Q}}[G] \) is invertible, then \(a _{s} \) is also invertible and so \(a =a _{s}a _{u} \) with \(a _{u}=1+a _{s}^{-1}a _{n} \) unipotent and \(a _{s}a _{u}=a _{u}a _{s} \). Such a decomposition is again unique. We say that \({\mathbb{Z}}[G] \) has *multiplicative Jordan decomposition* property (MJD) if \(a _{s}, a _{u} \in {\mathbb{Z}}[G] \) for every invertible \(a \in {\mathbb{Z}}[G] \). See the survey (A. W. Hales, I. B. S. Passi, in: *Algebra, Some Recent Advances*, Birkh\"{a}user, Basel, 1999, 75--87).

Is it true that there are only finitely many isomorphism classes of finite 2-groups G such that ${\mathbb{Z}}[G]$ has MJD but not AJD?

问题集入口：https://kourovkanotebookorg.wordpress.com/

03703 | KOU-16.2

Kourovka Notebook Problem 16.2

S / solved | Kourovka 群论问题集

A group G is *subgroup-separable* if for any subgroup $H\leq G$ and element $x\in G\setminus H$ there is a homomorphism to a finite group $f: G\rightarrow F$ such that $f(x)\not\in f(H)$. Is it true that a finitely generated solvable group is locally subgroup-separable if and only if it does not contain a solvable Baumslag--Solitar group? Solvable Baumslag--Solitar groups are $BS(1,n)= \left< a, b \mid bab^{-1}=a^n\right>$ for $n>1$.

Background: It is known that a finitely generated solvable group is subgroup-separable if and only if it is polycyclic (R. C. Alperin, in: *Groups--Korea'98 (Pusan)*, de Gruyter, Berlin, 2000, 1--5).

Kourovka Notebook Problem 16.29

O / open | Kourovka 群论问题集

Which finite simple groups of Lie type G have the following property: for every semisimple abelian subgroup A and proper subgroup H of G there exists $x\in G$ such that $A^x\cap H=1$?

This property holds when A is a cyclic subgroup (J. Siemons, A. Zalesskii, *J. Algebra*, **256** (2002), 611--625), as well as when A is contained in some maximal torus and $G=PSL_n(q)$ (J. Siemons, A. Zalesskii, *J. Algebra*, **226** (2000), 451--478). Note that if $G=L_2(5)$, $A=2\times 2$, and $H=5:2$ (in Atlas notation), then $A^x\cap H>1$ for every $x\in G$ (this example was communicated to the author by V. I. Zenkov).

03771 | KOU-16.82

Kourovka Notebook Problem 16.82

S / solved | Kourovka 群论问题集

Let $\mathcal{X}$ be a non-empty class of finite groups closed under taking homomorphic images, subgroups, and direct products. With every group $G\in\mathcal{X}$ we associate some set $\tau(G)$ of subgroups of G. We say that τ is a *subgroup functor on* $\mathcal{X}$ if:

1) $G\in\tau(G)$ for all $G\in\mathcal{X}$, and

2) for each epimorphism $\varphi :A\mapsto B$, where $A,B\in\mathcal{X}$, and for any $H\in\tau(A)$ and

$T\in\tau(B)$ we have $H^{\varphi}\in\tau(B)$ and $T^{\varphi^{-1}}\in\tau(A)$.

A subgroup functor τ is *closed* if for each group $G\in{\mathcal{X}}$ and for every subgroup $H\in {\mathcal{X}} \cap \tau (G)$ we have $\tau (H)\subseteq \tau (G)$. The set $F(\mathcal {X})$ consisting of all closed subgroup functors on $\mathcal{X}$ is a lattice (in which $\tau _1 \leq \tau _2$ if and only if $\tau_1 (G) \subseteq \tau_2 (G)$ for every group $G\in\mathcal{X}$). It is known that $F(\mathcal {X})$ is a chain if and only if $\mathcal{X}$ a class of p-groups for some prime p (Theorem 1.5.17 in S. F. Kamornikov and M. V. Sel'kin, *Subgroups functors and classes of finite groups*, Belaruskaya Navuka, Minsk, 2001 (Russian)).

Is there a non-nilpotent class $\mathcal{X}$ such that the width of the lattice $F(\mathcal {X})$ is at most $|\pi(\mathcal{X})|$ where $\pi (\mathcal{X})$ is the set of all prime divisors of the orders of the groups in $\mathcal{X}$?

Kourovka Notebook Problem 16.99

O / open | Kourovka 群论问题集

Suppose that G is a finite solvable group, $A \leq \mathrm{Aut} G$, \ $C_G(A)=1$, the orders of G and A are coprime, and let $l(A)$ be the length of the longest chain of nested subgroups of A. Is the Fitting height of G bounded above by $l(A)$?

For A solvable the question coincides with 5.30. It is proved that for any finite group A, first, there exist G with $h(G)=l(A)$ and, second, there is a finite set of primes π (depending on A) such that if $|G|$ is coprime to each prime in π, then $h(G)\leq l(A)$. See (A. Turull, *Math. Z.*, **187** (1984), 491--503).

Conjecture: A finite group is not simple if it has an irreducible complex character of odd degree vanishing on a class of odd length.

If true, this implies the solvability of groups of odd order, so a proof independent of CFSG is of special interest.

问题集入口：https://kourovkanotebookorg.wordpress.com/

03793 | KOU-17.101

Kourovka Notebook Problem 17.101

O / open | Kourovka 群论问题集

According to P. Hall, a group G is said to be *homogeneous* if every isomorphism of its finitely generated subgroups is induced by an automorphism of G. It is known (Higman--Neumann--Neumann) that every group is embeddable into a homogeneous one. Is the same true for the category of representations of groups? A representation (V,G) is finitely generated if G is a finitely generated group, and V a finitely generated module over the group algebra of G.

03800 | KOU-17.109

Kourovka Notebook Problem 17.109

O / open | Kourovka 群论问题集

A non-trivial group word w is *uniformly elliptic* in a class $\mathcal{C}$ if there is a function $f:\mathbb{N}\rightarrow\mathbb{N}$ such that the width of w in every d-generator $\mathcal{C}$-group G is bounded by $f(d)$ (i. e. every element of the verbal subgroup $w(G)$ is equal to a product of $f(d)$ values of w or their inverses). If $\mathcal{C}$ is a class of finite groups, this is equivalent to saying that in every finitely generated pro-$\mathcal{C}$ group G the verbal subgroup $w(G)$ is closed. A. Jaikin-Zapirain (*Revista Mat. Iberoamericana*, **24** (2008), 617--630) proved that w is uniformly elliptic in finite p-groups if and only if $w\notin F^{\prime\prime}(F^{\prime})^{p}$, where F is the free group on the variables of w. Is it true that w is uniformly elliptic in $\mathcal{C}$ if and only if $w\notin F^{\prime\prime}(F^{\prime})^{p}$ for every prime p in the case where $\mathcal{C}$ is the class of all

a) finite soluble groups?

b) finite groups?

See also Ch. 4 of (D. Segal, *Words: notes on verbal width in groups*, LMS Lect. Note Series, **361**, Cambridge Univ. Press, 2009.

a) Is it true that for each word w, there is a function $h:\mathbb{N}\times \mathbb{N}\rightarrow\mathbb{N}$ such that the width of w in every finite p-group of Pr\"{u}fer rank r is bounded by $h(p,r)$?

b) If so, can $h(p,r)$ be made independent of p?

An affirmative answer to a) would imply A. Jaikin-Zapirain's result (*ibid.*) that every word has finite width in each p-adic analytic pro-p group, since a pro-p group is p-adic analytic if and only if the Pr\"{u}fer ranks of all its finite quotients are uniformly bounded.

Kourovka Notebook Problem 17.35

S / solved | Kourovka 群论问题集

Suppose we have a finite two-colourable triangulation of the sphere, with triangles each coloured either black or white so that no pair of triangles with the same colour share an edge. On each vertex we write a generator, and we assume the generators commute. We use these generators to generate an abelian group G_W with relations stating that the generators around each white triangle add to zero. Doing the same thing with the black triangles, we generate a group G_B.

Conjecture: G_W is isomorphic to G_B.

Let G be a finite simple group of Lie type defined over a field of characteristic p whose Lie rank is at least three, and V an absolutely irreducible G-module over a field of characteristic that does not divide p. It is true that the split extension of V by G must contain an element whose order is distinct from the order of any element of G? The case of $G=U_n(p^m)$ is of special interest.

Given normal subgroups $R_1,\dots, R_n$ of a group G, let $\displaystyle [[R_1,\dots, R_n]]:=\prod \Big[\bigcap_{i\in I}R_i,\bigcap_{j\in J}R_j\Big] $, where the product is over all $I\cup J=\{1,\dots,n\}$, $ I\cap J=\varnothing$. Let G be a free group, and let $R_i=\langle r_i\rangle^G$ be the normal closures of elements $r_i\in G$. It is known (B. Hartley, Yu. Kuzmin, *J. Pure Appl. Algebra*, **74** (1991), 247--256) that the quotient $(R_1\cap R_2)/{[R_1, R_2]}$ is a free abelian group. On the other hand, the quotient $(R_1\cap \dots \cap R_n)/[[R_1,\dots, R_n]] $ has, in general, non-trivial torsion for $n\geq 4$. Is this quotient always torsion-free for $n=3$? This is known to be true if r_1,r_2,r_3 are not proper powers in G.

A group G is said to have *property (τ)* if its trivial representation is an isolated point in the subspace of irreducible representations with finite images (in the topological unitary dual space of G). Is it true that there exists a finitely generated group satisfying property (τ) that homomorphically maps onto every finite simple group?

The motivation is the theorem in (E. Breuillard, B. Green, M. Kassabov, A. Lubotzky, N. Nikolov, T. Tao) saying that there are $\epsilon>0$ and k such that every finite simple group G contains a generating set S with at most k elements such that the Cayley graph of G with respect to S is an ϵ-expander. In (M. Ershov, A. Jaikin-Zapirain, M. Kassabov, *Mem. Amer. Math. Soc.*, **1186**, 2017) it is proved that there exists a group with Kazhdan's property (T) that maps onto every simple group of Lie type of rank ${}\geq 2$. (A group G is said to have *Kazhdan's property* (T) if its trivial representation is an isolated point in the unitary dual space of G.)

(D. B. A. Epstein). Is it true that the group $ H = (\mathbb{Z}_3 \times \mathbb{Z}) * (\mathbb{Z}_2 \times \mathbb{Z}) = \langle x, y, z, t \mid x^3 = z^2 = [x, y] = [z, t] = 1 \rangle$ cannot be defined by three relators in the generators x, y, z, t?

It is known that the relation module of the group H has rank 3 \ (K. W. Gruenberg, P. A. Linnell, *J. Group Theory*, **11**, no. 5 (2008), 587--608). An affirmative answer would give a solution of the relation gap problem.

03952 | KOU-18.23

Kourovka Notebook Problem 18.23

S / solved | Kourovka 群论问题集

The normal covering number of the symmetric group S_n of degree n is the minimum number $\gamma(S_n)$ of proper subgroups $H_1,\ldots,H_{\gamma(S_n)}$ of S_n such that every element of S_n is conjugate to an element of H_i, for some $i=1,\dots, \gamma(S_n)$. Write $n=p_1^{\alpha_1}\cdots p_r^{\alpha_r}$ for primes $p_1<\cdots<p_r$ and positive integers $\alpha_1,\ldots,\alpha_r$.

Conjecture: \[\gamma(S_n)=\left\{ \begin{array}{lcl} \frac{n}{2}\left(1-\frac{1}{p_1}\right)&&\textrm{if }r=1 \textrm{and} \alpha_1=1\\ \frac{n}{2}\left(1-\frac{1}{p_1}\right)+1&&\textrm{if }r=1 \textrm{and} \alpha_1\geq 2\\ \frac{n}{2}\left(1-\frac{1}{p_1}\right)\left(1-\frac{1}{p_2}\right)+1&&\textrm{if }r=2 \textrm{and} \alpha_1+\alpha_2=2\\ \frac{n}{2}\left(1-\frac{1}{p_1}\right)\left(1-\frac{1}{p_2}\right)+2&&\textrm{if }r\geq 2 \textrm{and} \alpha_1+\cdots+\alpha_r\geq 3\\ \end{array} \right. \] This is the strongest form of the conjecture. We would be also interested in a proof that this holds for n sufficiently large. The result for $r\leq 2$, which includes the first three cases above, is proved for n odd (D. Bubboloni, C. E. Praeger, *J. Combin. Theory (A)*, **118** (2011), 2000--2024). When $r\geq3$ we know that $cn\leq \gamma(S_n)\leq \frac{2}{3}n$ for some positive constant c (D. Bubboloni, C. E. Praeger, P. Spiga, *J. Algebra*, **390** (2013) 199--215). We showed that the conjectured value for $\gamma(S_n)$ is an upper bound, by constructing a normal covering for S_n with this number of conjugacy classes of maximal subgroups, and gave further evidence for the truth of the conjecture in other cases (D. Bubboloni, C. E. Praeger, P. Spiga, *Int. J. Group Theory*, **3**, no. 2 (2014), 57--75).

Kourovka Notebook Problem 18.34

O / open | Kourovka 群论问题集

Let G be a topological group and $S={G_0\leq \dots \leq G_n=G}$ a subnormal series of closed subgroups. The *infinite-length* of S is the cardinality of the set of infinite factors G_i/G_{i-1}. The *virtual length* of G is the supremum of the infinite lengths taken over all such series of G. It is known that if G is a pronilpotent group with finite virtual length then every closed subnormal subgroup is topologically finitely generated (N. Gavioli, V. Monti, C. M. Scoppola, *J. Austral. Math. Soc.*, **95**, no. 3 (2013), 343--355). Let G be a pro-p group (or more generally a pronilpotent group). If every closed subnormal subgroup of G is tolopologically finitely generated, is it true that G has finite virtual length?

问题集入口：https://kourovkanotebookorg.wordpress.com/

03965 | KOU-18.35

Kourovka Notebook Problem 18.35

O / open | Kourovka 群论问题集

A family ${\mathscr F}$ of group homomorphisms $A\to B$ is *separating* if for every nontrivial $a\in A$ there is $f\in {\mathscr F}$ such that $f(a)\ne 1$, and *discriminating* if for any finitely many nontrivial elements $a_1,\dots ,a_n\in A$ there is $f\in {\mathscr F}$ such that $f(a_i)\ne 1$ for all $i=1,\dots , n$. Let G be a relatively free group of rank 2 in the variety of metabelian groups. Let T be a metabelian group in which the centralizer of every nontrivial element is abelian. If T admits a separating family of surjective homomorphisms $T\to G$ must it also admit a discriminating family of surjective homomorphisms $T\to G$?

A positive answer would give a metabelian analogue of a classical theorem of B. Baumslag.

问题集入口：https://kourovkanotebookorg.wordpress.com/

03966 | KOU-18.36

Kourovka Notebook Problem 18.36

S / solved | Kourovka 群论问题集

There are groups of cardinality at most $2^{\aleph_{0}}$, even nilpotent of class 2, that cannot be embedded in $S:=Sym(\mathbb{N})$ (V. A. Churkin, *Algebra and model theory* (Novosibirsk State Tech. Univ.), **5** (2005), 39--43 (Russian)). One condition which might characterize subgroups of S is the following. Consider the metric d on S where for all $x\neq y$ we define $d(x,y):=2^{-k}$ when k is the least element of the set $\mathbb{N}$ such that $k^{x}\neq k^{y}$. Then (S,d) is a separable topological group, and so each subgroup of S (not necessarily a closed subgroup of (S,d)) is a separable topological group under the induced metric. Is it true that every group G for which there is a metric $d^{\prime}$ such that $(G,d^{\prime})$ is a separable topological group is (abstractly) embeddable in S?

Note that any such group G can be embedded as a *section* in S.

b) Are there any intervals J in ${\mathbb{R}}$ such that the set of values of scl on $[F,F]$ is dense in J?

c) Is there some $T\in {\mathbb{R}}$ such that every rational number ${}\ge T$ is a value of $scl(g)$ for $g\in [F,F]$?

问题集入口：https://kourovkanotebookorg.wordpress.com/

03973 | KOU-18.42

Kourovka Notebook Problem 18.42

O / open | Kourovka 群论问题集

For an orientation-preserving homeomorphism $f:S^1\to S^1$ of a unit circle S^1, let $\tilde f$ be its lifting to a homeomorphism of ${\mathbb{R}}$; then the *rotation number* of f is defined to be the limit $\lim _{n\to \infty} (\tilde f^n(x)-x)/n$ (which is independent of the point $x\in S^1$). Let F be a free group of rank 2 with generators a,b. For $ w\in F$ and $r,s\in {\mathbb{R}}$, let $R(w,r,s)$ denote the maximum value of the (real-valued) rotation number of w, under all representations from F to the universal central extension of $Homeo^+(S^1)$ for which the rotation number of a is r, and the rotation number of b is s.

a) If r,s are rational, must $R(w,r,s)$ be rational?

b) Let $R(w,r-,s-)$ denote the supremum of the rotation number of w (as above) under all representations for which a and b are conjugate to rotations through r and s, respectively (in the universal central extension of $Homeo^+(S^1)$). Is $R(w,r-,s-)$ always rational if r and s are rational?

c) *Weak Slippery Conjecture*: Let w be a word containing only positive powers of a and b. A pair of values (r,s) is *slippery* if there is a strict inequality $R(w,r',s') < R(w,r-,s-)$ for all $r'<r$, $s'<s$. Is it true that then $R(w,r-,s-) = h_a(w)r + h_b(w)s$, where $h_a(w)$ counts the number of a's in w, and $h_b(w)$ counts the number of b's in w?

d) *Slippery Conjecture*: More precisely, is it always (without assuming (r,s) being slippery) true that if w has the form $w=a^{\alpha_1}b^{\beta_1}\cdots a^{\alpha_m}b^{\beta_m}$ (all positive) and $R(w,r,s) = p/q$ where p/q is reduced, then $|p/q - h_a(w)r - h_b(w)s| \le m/q$?

Kourovka Notebook Problem 18.9

S / solved | Kourovka 群论问题集

Does there exist a subgroup-closed saturated formation $\mathfrak{F}$ of finite groups properly contained in $\mathfrak{E}_{\pi}$, where $\pi = char(\mathcal{F})$, satisfying the following property: if $G \in \mathfrak{F}$, then there exists a prime p (depending on the group G) such that the wreath product $C_p\wr G$ belongs to $\mathfrak{F}$, where C_p is the cyclic group of order p?

问题集入口：https://kourovkanotebookorg.wordpress.com/

04026 | KOU-18.90

Kourovka Notebook Problem 18.90

O / open | Kourovka 群论问题集

Prove that the group $Y(m,n) =\langle a_{1},a_{2},\dots,a_{m} \mid a_{k}^{n} =1 \text{ }(1\leq k\leq m)\text{, } (a_{k}^{i}a_{l}^{i}) ^{2} =e\text{ }(1\leq k<l\leq m\text{, } 1\leq i\leq \frac{n}{2})\rangle $ is finite for every pair $(m,n) $.

Some known cases are (where C_n denotes a cyclic group of order n): $Y(m,2)=C_{2}^{m}$; $Y(m;3)={A}_{m+2}$ (presentation by Carmichael); $Y(m;4)$ has order $2^{\frac{m(m+3)}{2}}$, nilpotency class 3 and exponent 4; \ $Y(2,n)$ is the natural extension of the augmentation ideal $\omega (C_{n})$ of $GF(2)[C_{n}]$ by C_{n} (presentation by Coxeter); $Y(3,n)\cong SL(2,\omega (C_{n}))$.

These groups have connections with classical groups in characteristic 2. When n is odd, the group $Y(m,n)$ has the following presentation, where $\tau _{ij}$ are transpositions: $y(m,n) =\langle a,\text{ }{\mathbb{S}}_{m}\text{ }\mid a^{n}=e, [\tau _{12}^{a^{i}},\tau _{12}] =e\; (1\leq i\leq \frac{n}{2}) , \tau _{12}^{1+a+\dots+a^{n-1}} =e,\text{ } \tau _{i,i+1}a\tau _{i,i+1} =a^{-1}\text{ }(2\leq i\leq m-1) \rangle$, and it is known that, for example, $y(3,5) \cong SL(2,16)\cong \Omega ^{-}(4,4)$, $y(4,5)\cong Sp(2,16)\cong \Omega (5,4)$, $y(5,5) \cong SU(4,16)\cong \Omega ^{-}(6,4)$, $y(6,5)\cong 4^{6}\Omega ^{-}(6,4)$, $ y(3,7) \cong SL(2,8)^{2}\cong \Omega ^{+}(4,8)$, $y(4,7)\cong Sp(4,8)\cong \Omega (5,8)$. Extensive computations by Felsch, Neub\"user and O'Brien confirm this trend. Different types reveal Bott periodicity and a connection with Clifford algebras.

Kourovka Notebook Problem 19.1

O / open | Kourovka 群论问题集

An element g of a group G is a *non-near generator* of G if for every subset $S\subseteq G$ such that $|G:\langle g,S\rangle|<\infty$ it follows that $|G:\langle S\rangle|<\infty$. The set of all non-near generators of G forms a characteristic subgroup of G called the *lower near Frattini subgroup* of G, denoted by $\lambda(G)$. A subgroup $M\leq G$ is *nearly maximal* in G if it is maximal with respect to being of infinite index in G. The intersection of all nearly maximal subgroups forms a characteristic subgroup called the *upper near Frattini subgroup* of G, denoted by $\mu(G)$. In general, $\lambda(G)\leq\mu(G)$. If $\lambda(G)=\mu(G)$, then this subgroup is called the *near Frattini subgroup* of G, denoted by $\psi(G)$.

a) Is it true that $\psi(G)=1$ if G is the knot group of any product of knots?

b) Is it true that $\psi(G)=1$ if G is a cable knot group?

Does there exist a constant c such that the number of conjugacy classes in a finite group G is always at least $c \log_2 |G|$?

Editors' comment of 2021: It is proved that every group G contains at least $\varepsilon \log |G|/(\log \log |G|)^8$ conjugacy classes for some fixed $\varepsilon > 0$ (L. Pyber, *J. London Math. Soc. (2)*, **46**, no. 2 (1992), 239--249). It is also proved that for every $\varepsilon > 0$ there exists $\delta > 0$ such that every finite group G of order at least 3 has at least $\delta \log _2|G|/(\log_2 \log _2|G|)^{3+\varepsilon}$ conjugacy classes (B. Baumeister, A. Mar\'oti, H. P. Tong-Viet, *Forum Math.*, **29**, no. 2 (2017), 259--275).

(Well-known problem). Suppose that G is a finitely presented group such that the set of first Betti numbers over all the finite index subgroups of G is unbounded above. (Here, the first Betti number is the maximum n for which there is a surjective homomorphism onto $\mathbb{Z}^n$.)

a) Must G have a finite index subgroup with a surjective homomorphism to a non-abelian free group?

b) Can G even be soluble?

问题集入口：https://kourovkanotebookorg.wordpress.com/

04057 | KOU-19.18

Kourovka Notebook Problem 19.18

O / open | Kourovka 群论问题集

Given an infinite set Ω, define an algebra A (the *reduced incidence algebra of finite subsets*) as follows. Let V_n be the set of functions from the set of $n $-element subsets of Ω to the rationals $\mathbb{Q}$. Now let $A=\bigoplus V_n$, with multiplication as follows: for $f\in V_n$, $g\in V_m$, and $|X|=m+n$, let $(fg)(X)=\sum f(Y)g(X\setminus Y)$, where the sum is over the $n $-element subsets Y of X. If G is a permutation group on Ω, let A^G be the algebra of $G $-invariants in A.

Suppose that G has no finite orbits on Ω. It is known that then A^G is an integral domain (M. Pouzet, *Theor. Inf. App.* **42**, no. 1 (2008), 83--103). Is it true that the quotient of A^G by the ideal generated by constant functions is also an integral domain?

问题集入口：https://kourovkanotebookorg.wordpress.com/

04058 | KOU-19.19

Kourovka Notebook Problem 19.19

O / open | Kourovka 群论问题集

A finite transitive permutation group G is said to have the *road closure property* if, given any orbit O of G on 2-sets, and any proper block of imprimitivity for G acting on O, the graph with edge set $O\setminus B$ is connected. Such a group must be primitive, and basic (not contained in a wreath product with the product action); it cannot have an imprimitive subgroup of index 2. In addition, such a group cannot be one of the permutation groups arising from triality (whose socle is $D_4(q)$ and intersects the point stabiliser in the parabolic subgroup corresponding to the three leaves in the Coxeter--Dynkin diagram for D_4).

Classify the basic primitive groups G which do not have the road closure property. In particular, is it true that such a group either has a subgroup of index at most 3 or is almost simple?

Kourovka Notebook Problem 19.27

O / open | Kourovka 群论问题集

(Well-known question). A finitely generated group G that acts on a tree in such a way that all vertex and edge stabilizers are infinite cyclic groups is called a generalized Baumslag--Solitar group. The Bass--Serre theory gives finite presentations of such groups. Is the isomorphism problem soluble for generalized Baumslag--Solitar groups?

问题集入口：https://kourovkanotebookorg.wordpress.com/

04068 | KOU-19.28

Kourovka Notebook Problem 19.28

O / open | Kourovka 群论问题集

Let G be a group, and φ an automorphism of G. Elements $x,y\in G$ are said to be φ-conjugate if $x=z^{-1}y\varphi (z)$ for some $z\in G$. The φ-conjugacy is an equivalence relation; the number of φ-conjugacy classes is denoted by $R(\varphi)$.

Conjecture: If a finitely generated residually finite group G has an automorphism φ such that $R(\varphi)$ is finite, then G has a soluble subgroup of finite index.

The conjecture is proved if φ has prime order (E. Jabara, *J. Algebra*, **320**, no. 10 (2008), 3671--3679). If G is infinitely generated, then G does not have to be almost solvable (K. Dekimpe, D. Gonçalves, *Bull. London Math. Soc.*, **46**, no. 4 (2014), 737--746), but if it is of finite upper rank, then it has to be almost solvable (E. Troitsky, *J. Group Theory*, **28**, no. 1 (2025), 151--164).

Suppose that H is a word-hyperbolic subgroup of a word-hyperbolic group G such that the inclusion of H to G extends to a continuous H-equivariant map $j:\partial H\to \partial G$ between their hyperbolic boundaries. If such an extension exists, it is unique and j is called the *Cannon--Thurston map*.

a) Is it true that for every point $p\in \partial G$ its full preimage $j^{-1}(p)$ is finite?

b) Moreover, is it true that there is a number $N=N(G,H)<\infty$ such that for every $p\in \partial G$ the full preimage $j^{-1}(p)$ consists of at most N points?

The answer to both questions is ``yes'' in all the cases where the Cannon--Thurston map is known to exist and where it has been possible to analyze the multiplicity of this map. This includes the original set-up considered by Cannon and Thurston where H is the surface group, and G is the fundamental group of a closed hyperbolic 3-manifold fibering over the circle with that surface as a fiber. In this case, $j:\mathbb{S}^1\to\mathbb{S}^2$ is a uniformly finite-to-one continuous surjective `Peano curve'.

Let \(G\) be a group generated by 3 class transpositions (see the definition in 17.57), and let \(m\) be the least common multiple of the moduli of the residue classes interchanged by the generators of \(G\). Assume that \(G\) does not setwisely stabilize any union of residue classes modulo \(m\) except for \(\varnothing\) and \(\mathbb{Z}\), and assume that the integers \(0, 1, \dots, 42\) all lie in the same orbit under the action of \(G\) on \(\mathbb{Z}\). Is the action of \(G\) on \(\mathbb{N}\cup \{0\}\) necessarily transitive?

The bound 42 cannot be replaced by a smaller number, since the finite group \(\langle \tau_{0(2),1(2)}, \tau_{0(3),2(3)}, \tau_{0(7),6(7)} \rangle\) acts transitively on the set \(\{0, \dots, 41\}\), as well as on the set of residue classes modulo 42.

Let K be a finite extension of degree n of a field k of odd characteristic. The multiplicative group K^{*} embeds into the group of all k-linear automorphisms $\mathrm{Aut}_{k}(K)$ by the rule $t(x) = tx$ for all $x\in K$. For a fixed basis of K over k, the group $\mathrm{Aut}_k(K)$ is isomorphic to $GL(n,k)$. The image of K^{*} is called a *nonsplit maximal torus* corresponding to the extension K/k and is denoted by $T(K/k)$. A subgroup of $GL(n,k)$ is said to be *rich in transvections* if it contains all elementary transvections.

Let H be a subgroup of $GL(n, k)$ which contains $T(K/k)$ and a one-dimensional transformation. Is H rich in transvections?

04108 | KOU-19.64

Kourovka Notebook Problem 19.64

O / open | Kourovka 群论问题集

Let G be a group, and $(g_1, \ldots , g_n)$ a tuple of its elements. The *type* of this tuple in G, denoted $Tp^G(g_1, \ldots , g_n)$, is the set of all first order formulas in free variables $x_1, \ldots ,x_n$ in the standard group theory language which are true on $(g_1, \ldots , g_n)$ in G. Two groups G and H are called *isotypic* if for every tuple of elements $\bar h=(h_1,\ldots,h_n)$ in H there is a tuple $\bar g =(g_1,\ldots,g_n)$ in G, such that $Tp(\bar h)=Tp(\bar g)$ and vice versa, for every tuple $\bar g$ in G there is a tuple $\bar h$ in H such that $Tp(\bar h)=Tp(\bar g)$.

Is it true that every two isotypic finitely generated groups are isomorphic?

The answer is positive if one of the finitely generated groups is free (R. Sklinos), abelian (G. Zhitomirski), virtually polycyclic, metabelian, free solvable (A. Myasnikov, N. Romanovskii), co-Hopfian (in particular homogeneous), finitely presented Hopfian or geometrically Noetherian Hopfian (R. Sklinos). In particular, torsion-free hyperbolic groups, braid groups, linear groups, mapping class groups of compact surfaces, limit groups, quasi-cyclic groups, $Out(F_n)$, $n > 2$, irreducible arithmetic lattices (which are not virtually free groups) in semi-simple Lie groups, are of such kind (R. Sklinos).

A word in an alphabet $A = \{ a_1, a_2, \ldots, a_n \}$ is called a palindrome if it reads the same from left to right and from right to left. Let k a non-negative integer. A word in the alphabet A is called an *almost k-palindrome* if it can be transformed into a palindrome by changing $\leq k$ letters in it. (So an almost 0-palindrome is a palindrome.) Let elements of a free group $F_2 = \langle x, y \rangle$ be represented as words in the alphabet $\{ x^{\pm 1}, y^{\pm 1} \}$. Do there exist positive integers m and c such that every element in F_2 is a product of $\leq c$ almost m-palindromes?

It is known that for $m=0$ there is no such a number c.

04129 | KOU-19.83

Kourovka Notebook Problem 19.83

O / open | Kourovka 群论问题集

An element g of a group G is almost Engel if there is a finite set ${\mathscr E}(g)$ such that for every $x\in G$ all sufficiently long commutators $[x, {}_n g]$ belong to ${\mathscr E}(g)$, that is, for every $x\in G$ there is a positive integer $n(x,g)$ such that $[x, {}_n g]\in {\mathscr E}(g)$ whenever $n\geq n(x,g)$. By a linear group we understand a subgroup of $GL(m,F)$ for some field F and a positive integer m.

Is the set of almost Engel elements in a linear group always a subgroup?

S / solved | Kourovka 群论问题集

Let $\mathbb{P}$ be the set of all primes, and let $\sigma =\{\sigma_{i} \mid i\in I\}$ be some partition of $\mathbb{P}$ into disjoint subsets. A finite group G is said to be *σ-primary* if G is a σ_{i}-group for some i; *σ-nilpotent* if G is a direct product of σ-primary groups; *σ-soluble* if every chief factor of G is σ-primary. A subgroup A of a finite group G is said to be \emph{${\sigma}$-subnormal in G} if there is a chain $A=A_{0} \leq A_{1} \leq \cdots \leq A_{n}=G$ such that for every i either $A_{i-1} \trianglelefteq A_{i}$ or $A_{i}/(A_{i-1})_{A_{i}}$ is ${\sigma}$-primary, where $(A_{i-1})_{A_{i}}$ is the largest normal subgroup of A_{i} contained in A_{i-1}.

Suppose that a subgroup A of a finite group G is ${\sigma}$-subnormal in $\langle A, A^{x} \rangle$ for all $x\in G$. Is it true that then A is ${\sigma}$-subnormal in G?

An affirmative answer is known if $\sigma =\{\{2\}, \{3 \}, \ldots \}$ (Wielandt).

Kourovka Notebook Problem 19.91

O / open | Kourovka 群论问题集

Let G be a finite group with an abelian Sylow p-subgroup A. Suppose that B is a strongly closed elementary abelian subgroup of A. Without invoking the Classification Theorem for Finite Simple Groups (CFSG), prove that G has a normal subgroup N such that $B =\Omega _1(A\cap N)$.

For $p = 2$, this is a corollary of a theorem of Goldschmidt. For p odd, this has been proved by Flores and Foote (*Adv. Math.*, **222** (2009), 453--484), but their proof relies on CFSG. A CFSG-free proof in the special case when $p = 3$ and A has 3-rank 3 would already be quite interesting. This case arises in Aschbacher's treatment of the $e(G) = 3$ problem, and a proof would provide an alternative to part of his argument. (For this application, one could assume that all proper simple sections of G are known.)

04178 | KOU-2.43

Kourovka Notebook Problem 2.43

S / solved | Kourovka 群论问题集

A group G is called an *FN-group* if the groups $\gamma_ iG/\gamma _{i+1}G$ are free abelian and $\bigcap_{i=1}^{\infty} \gamma _iG = 1$, where $\gamma _{i+1}G=[\gamma _{i}G, G]$. A variety of groups ${\mathfrak{M}}$ is called a *Σ-variety* (where Σ is an abstract property) if the ${\mathfrak{M}}$-free groups have the property Σ.

a) Which properties Σ are preserved under multiplication and intersection of varieties? Is the FN property preserved under these operations?

b) Are all varieties obtained by multiplication and intersection from the nilpotent varieties ${\mathfrak{N}}_1$, ${\mathfrak{N}}_2, \ldots $ (where ${\mathfrak{N}}_1$ is the variety of abelian groups) FN-varieties?

问题集入口：https://kourovkanotebookorg.wordpress.com/

a) Does there exist an axiomatizable class of lattices ${\mathfrak{K}}$ such that the lattice of all subsemigroups of a semigroup S is isomorphic to some lattice in ${\mathfrak{K}}$ if and only if S is a free group?

b) The same question for free abelian groups.

Analogous questions have affirmative answers for torsion-free groups, for non-periodic groups, for abelian torsion-free groups, for abelian non-periodic groups, for orderable groups (the corresponding classes of lattices are even finitely axiomatizable). Thus, in posed questions one may assume from the outset that the semigroup S is a torsion-free group (respectively, a torsion-free abelian group).

问题集入口：https://kourovkanotebookorg.wordpress.com/

04218 | KOU-2.82

Kourovka Notebook Problem 2.82

O / open | Kourovka 群论问题集

Can the class of groups with the $n $th Engel condition $[x,\underbrace{y,\ldots ,y}_{n}]=1$ be defined by identical relations of the form $u=v$, where u and v are words without negative powers of variables? This can be done for $n=1, 2, 3$ (A. I. Shirshov, *Algebra i Logika*, **2**, no. 5 (1963), 5--18 (Russian)).

Editors' comment: This has also been done for $n=4$ (G. Traustason, *J. Group Theory*, **2**, no. 1 (1999), 39--46). As remarked by O. Macedo\'nska, this is also true for the class of locally graded n-Engel groups because by (Y. Kim, A. Rhemtulla, in *Groups--Korea'94*, de Gruyter, Berlin, 1995, 189--197) such a group is locally nilpotent and then by (R. G. Burns, Yu. Medvedev, *J. Austral. Math. Soc.*, **64** (1998), 92--100) such a group is an extension of a nilpotent group of n-bounded class by a group of n-bounded exponent; then a classical result of Mal'cev implies that such groups satisfy a positive law.

For $k\geq1$, a group G is said to be *totally k-closed* if in each of its faithful permutation representations, say on a set Ω, G is the largest subgroup of $\mathrm{Sym}(\Omega)$ which leaves invariant each of the G-orbits in the induced action on the set of ordered k-tuples Ω^k.

Are there any finite insoluble totally 2-closed groups with nontrivial Fitting subgroup?

The finite totally 2-closed groups which are either soluble or have trivial Fitting subgroup are known.

问题集入口：https://kourovkanotebookorg.wordpress.com/

04224 | KOU-20.10

Kourovka Notebook Problem 20.10

P / partially_solved | Kourovka 群论问题集

(a) If ${\mathscr U}$ and ${\mathscr U'}$ are nonprincipal ultrafilters on $\mathbb{N}$, can every group which can be written as a homomorphic image of an ultraproduct of groups with respect to ${\mathscr U}$ also be written as a homomorphic image of an ultraproduct of groups with respect to ${\mathscr U'}$?

(b) If the answer to (a) is negative, is it at least true that for any two nonprincipal ultrafilters ${\mathscr U}$ and ${\mathscr U'}$ on $\mathbb{N}$, there exists a nonprincipal ultrafilter ${\mathscr U''}$ on $\mathbb{N}$ such that every group which can be written as a homomorphic image of an ultraproduct of groups with respect to ${\mathscr U}$ or with respect to ${\mathscr U'}$ can be written as a homomorphic image of an ultraproduct with respect to ${\mathscr U''}$?

A positive answer to (b) would imply that the class of groups which can be written as homomorphic images of nonprincipal countable ultraproducts of groups is closed under finite direct products. See (G. M. Bergman, *Pacific J. Math.*, **274** (2015), 451--495).

Let $F \leq H$ be free groups such that there exists a free group G of finite rank with $F\leq G\leq H$, and let r be the least of the ranks of such groups G. Which, if any, of the following statements must hold?

(i) There is a largest G of rank r between F and H.

(i$'$) For any two G_1, G_2 of rank r between F and H, the subgroup $\langle G_1, G_2\rangle$ has rank r.

(ii) There is a smallest G of rank r between F and H.

(ii$'$) For any two G_1, G_2 of rank r between F and H, the subgroup $G_1\cap G_2$ has rank r.

If (i) holds for all such F and H, then so does (i$'$). If (ii) holds for all F, H, then so does (ii$'$). The converse of the former implication holds because subgroups of a free group of any fixed finite rank satisfy ACC, but I don't see a way to get the converse of the other implication.

Let $H(q,c) = \langle a,b,c,d \mid [b,a]=[d,c], \text{ of exponent } q, \text{ nilpotent of class } c\rangle$.

a) Is it true that the Schur multiplier $M(H(8,12))$ has exponent 32?

b) Is it true that the Schur multiplier $M(H(7,13))$ has exponent 49?

The difficulty is that these groups are too big to compute using current versions of the p-Quotient Algorithm, which use 32 bit arithmetic. So to tackle these groups it would help to have a version of the p-Quotient Algorithm using 64 bit arithmetic.

{(a)} If an abelian group can be written as a homomorphic image of a nonprincipal countable ultraproduct of *not necessarily* abelian groups G_i, must it be a homomorphic image of a nonprincipal countable ultraproduct of abelian groups? See (G. M. Bergman, *Pacific J. Math.*, **274** (2015), 451--495).

(b) If an abelian group can be written as a homomorphic image of a *direct product* of an infinite family of not necessarily abelian *finite* groups, can it be written as a homomorphic image of a direct product of finite abelian groups?

To see that neither question is trivial, choose for each $n > 0$ a finite group G_n which is perfect but has elements which cannot be written as products of fewer than n commutators. Then both the direct product of the G_n and any nonprincipal ultraproduct of those groups will have elements which are not products of commutators; hence its abelianization A will be nontrivial. There is no evident family of abelian groups from which to obtain A as an image of a nonprincipal ultraproduct, nor a family of finite abelian groups from which to obtain A as an image of a direct product.

04255 | KOU-20.14

Kourovka Notebook Problem 20.14

O / open | Kourovka 群论问题集

(a) Do there exist a variety $\mathfrak{V}$ of groups and a group $G\in \mathfrak{V}$ such that the coproduct in $\mathfrak{V}$ of two copies of G is embeddable in G, but the coproduct of three such copies is not? See (G. M. Bergman, *Indag. Math.*, **18** (2007), 349--403).

Given an embedding $G *_\mathfrak{V} G \to G$, one might expect the induced map \begin{center} $G*_\mathfrak{V} (G *_\mathfrak{V} G) \to G *_\mathfrak{V} G \to G $ \end{center} to be an embedding. But this is not automatic, because in a general group variety $\mathfrak{V}$, a map $G *_\mathfrak{V} A \to G *_\mathfrak{V} B$ induced by an embedding $A\to B$ is not necessarily again an embedding.

(b) If there exist $\mathfrak{V}$ and G as in (a), does there in fact exist an example with $\mathfrak{V}$ the variety of groups generated by G? For this and related questions, see (G. M. Bergman, *Algebra Number Theory*, **3** (2009), 847--879).

Let κ be an infinite cardinal. If a residually finite group G is embeddable in the full permutation group of a set of cardinality κ, must it be embeddable in the direct product of κ finite groups? See (G. M. Bergman, *Indag. Math.*, **18** (2007), 349--403).

The converse is true: any such direct product is residually finite and embeddable in the indicated permutation group. Also, the statement asked for becomes true if one replaces ``direct product of $\kappa$ finite groups'' by ``direct product of 2^κ finite groups'', since G has cardinality at most 2^κ, hence homomorphisms to that many finite groups can be chosen which, together, separate each element of G from e.

Kourovka Notebook Problem 20.36

O / open | Kourovka 群论问题集

The free Burnside group of exponent four on three generators, $B(3,4)$, has order 2^{69} as shown by Bayes, Kautsky, and Wamsley (1974). Their proof is based on a theorem of Sanov (1940) which shows that $B(n,4)$ is finite. Sanov's proof for $B(3,4)$ uses more than 2^{32} fourth powers, because the subgroup of $B(3,4)$ generated by two of its generators and the square of the third has order 2^{32}. It is also known that $B(3,4)$ needs at least 105 relations to define it, as shown by Havas and Newman (1980).

a) Can $B(3,4)$ be defined with fewer than a million fourth powers?

b) Can $B(3,4)$ be defined with fewer than a thousand fourth powers?

c) What is the smallest number of fourth powers which define $B(3,4)$?

A finite group G is said to be *cut* (or *inverse semi-rational*) if $\langle x \rangle = \langle y \rangle$ implies that x is conjugate to y or to y^{-1} for all $x, y \in G$.

a) Let $\mathbb{Q}(G)$ denote the field extension of the rationals obtained by adjoining all entries of the ordinary character table of G. Is there $c > 0$ such that $|\mathbb{Q}(G):\mathbb{Q}| \leqslant c$ for all cut groups? This is true if one assumes in addition that G is solvable (J. F. Tent, *J. Algebra*, **363** (2012), 73--82).

b) Is a Sylow 3-subgroup of a cut group also a cut group?

c) Let $\operatorname{O}_p(G)$ denote the largest normal p-subgroup of G. Let G be a solvable cut group. Is it true that for $p \in \{5, 7\}$ the exponent of $\operatorname{O}_p(G)$ divides p?

For additional information and some positive results see (*Adv. Group Theory Appl.*, **8**B, 2020, 157--160 or \texttt{https://arxiv.org/abs/2001.02637}).

For an irreducible complex character χ of a finite group G, the *codegree* of χ is defined by $\mathrm{cod}(\chi)=|G:\ker\chi|/\chi(1)$. Let $\mathrm{Cod}(G)$ be the set of irreducible character codegrees of G. *Conjecture*: If G has an element of order m, then m divides some member of $\mathrm{Cod}(G)$.

The conjecture is proved when m is a prime power (G. Qian, *Arch. Math.*, **97** (2011), 99--103); when m is square-free (I. M. Isaacs, *Arch. Math.*, **97** (2011), 499--501); or when G is solvable (G. Qian, *Bull. London Math. Soc.*, **53** (2021) 820--824); or when G is a symmetric or alternating group (E. Giannelli (*J. Algebra Appl.*, **23**, no. 9 (2024), article ID 2450144); or when G is an almost simple group (S. Y. Madanha, *Commun. Algebra*, **51**, no. 7 (2023), 3143--3151); or when $\mathbf{F}(G)=1$ (Z. Akhlaghi, E. Pacifici, L. Sanus, *J. Algebra*, **644** (2024), 428--441).

Let G be a finite group, and χ an irreducible complex character of G. We call χ a $\mathcal{P}$-character if χ is a constituent of $(1_H)^G$ for some maximal subgroup H of G; and χ is said to be monomial if χ is induced by a linear character of a subgroup of G.

Conjecture: G is solvable if and only if all its $\mathcal{P}$-characters are monomial.

The necessity part of the conjecture is true (G. Qian, Y. Yang, *Commun. Algebra*, **46**, no. 1 (2018), 167--175).

Does there exist a class $\mathfrak{X}$ of finite groups satisfying the following conditions:

(1) $\mathfrak{X}$ is closed with respect to taking subgroups and homomorphic images;

(2) the product of two normal $\mathfrak{X}$-subgroups of an arbitrary group is always an $\mathfrak{X}$-group;

(3) for every positive integer n, there exist a finite group and its conjugacy class D such that any n elements of D generate an $\mathfrak{X}$-subgroup, whereas $\langle D\rangle\notin\mathfrak{X}$.

It is known that there are no classes $\mathfrak{X}$ satisfying (1)--(3) that are closed with respect to extensions (D. O. Revin, *Algebra i Analiz*, **37**, no. 1 (2025), 141--176 (Russian)).

Let $\mathfrak{X}$ be a class of finite groups that is closed with respect to taking subgroups, homomorphic images, and extensions. A subgroup H of a finite group G is said to be \emph{$\mathfrak{X}$-submaximal} if there exists an embedding of G into a group G^* such that G is subnormal in G^* and H coincides with the intersection of G and an $\mathfrak{X}$-maximal subgroup of G^*. Suppose that all $\mathfrak{X}$-submaximal subgroups of a characteristic subgroup N of a finite group G are conjugate in N. Does it follow that HN/N is an $\mathfrak{X}$-submaximal subgroup of G/N for every $\mathfrak{X}$-submaximal subgroup H of G?

For normal subgroups N, this is not true even if N is an $\mathfrak{X}$-group or if N does not contain nontrivial $\mathfrak{X}$-subgroups. A positive answer is known in the case where N coincides with the $\mathfrak{F}$-radical of G for a Fitting class $\mathfrak{F}$.

Let F be a free group. An element $\omega\in F$ is said to be *primitive* if there is a minimal generating system of F that contains ω, *almost primitive* if it is primitive in each finitely generated proper subgroup of F containing ω, *tame almost primitive* if, whenever ω^α is contained in a subgroup H of F with $\alpha\ge 1$ minimal, either ω^α is primitive in H or the index of H in F is just α. In (B. Fine, A. Moldenhauer, G. Rosenberger, L. Wienke, *Topics in Infinite Group Theory: Nielsen Methods, Covering Spaces, and Hyperbolic Groups*, De Gruyter, Berlin, 2021) it is shown that $u=[a_1,b_1][a_2,b_2]\cdots [a_g,b_g]$ is tame almost primitive in the free group on $a_1, b_1,\dots ,a_g,b_g$ with $g\ge 1$, and $v=c_1 ^2\cdots c_p ^2$ is tame almost primitive in the free group on $c_1,\dots,c_p$ with $p\ge 2$.

Are there tame almost primitive elements in free groups other than u, v, and their product uv in the free group on $a_1, b_1,\dots ,a_g,b_g,c_1,\dots,c_p$?

Suppose G is a finite group and p a prime such that the number $s_p(G)=1+kp$ of Sylow p-subgroups P of G is greater than 1. By a theorem of Frobenius the set G_p of all p-elements in G has cardinality $|G_p|=|P|\cdot f_p(G)$ for some positive integer $f_p(G)$, and one easily gets that $f_p(G)=1+\ell(p-1)\le k-{k-1\over p-1}$. Usually, $\ell <k$ (but $\ell =k$ if $k<p$). Is always $\ell^p\ge k^{p-1}$?

Recently P. Gheri showed that $f_p(G)^p\ge s_p(G)^{p-1}$ if G is p-solvable (*Ann. Mat. Pura Appl. (4)*, **200** (2021), 1231--1243).

A group G is said to be *stable* if for any first-order formula $\phi(\bar{x}, \bar{y})$ (in the first-order language of groups $\{ \cdot , {}^{-1}, 1\}$) there exists a natural number n such that whenever there exist sequences of tuples of G, $(a_i)_{i<m}$, $(b_i)_{i<m}$ with $G\models \phi(a_i, b_j)$ if and only if $i<j$, then $m\leq n$. Sela proved that all torsion-free hyperbolic groups are stable.

a) Is there a non-stable hyperbolic group?

b) Is there a non-stable virtually free group?

c) Is $SL_2(\mathbb{Z})$ non-stable?

问题集入口：https://kourovkanotebookorg.wordpress.com/

04340 | KOU-20.92

Kourovka Notebook Problem 20.92

P / partially_solved | Kourovka 群论问题集

This question is about existence of an analogue of the Lazard correspondence for pre-Lie algebras and braces. A *pre-Lie algebra* A is a vector space with a bilinear operation $(x, y) \rightarrow xy$ satisfying $(xy)z -x(yz) = (yx)z - y(xz)$ for every $x,y,z\in A$. A pre-Lie algebra A is said to be *left nilpotent* if, for some $n\in \mathbb{N}$, $A\cdot (A\cdot(A\cdots A)))=0$ where A appears n times in the product. Recall that a set A with binary operations $+$ and $\circ $ is a *left brace* if $(A, +)$ is an abelian group, $(A, \circ)$ is a group, and $a\circ (b+c)+a=a\circ b+a\circ c$ for every $a,b,c\in A$. Let p be a prime, and $\mathbb{F}_{p}$ the field of p elements. A left brace A is called an $\mathbb{F}_p$-brace if its additive group is an $\mathbb{F}_p$-vector space such that $a*({\alpha }b)={\alpha }(a* b)$ for all $a,b\in A$, $ {\alpha }\in \mathbb{F}_p$, where $ a*b=a \circ b -a -b$. The idea of a connection between braces and pre-Lie algebras comes from a paper by W. Rump (2014).

a) Let A be an $\mathbb{F}_{p}$-brace of cardinality p^{k} for some k. Is it true that when p is sufficiently large relative to k, the set A with the same additive operation $+$ and with the operation $\cdot $ defined as $a\cdot b=-\sum_{i=0}^{p-2}{\frac 1{2^{i}}}((2^{i}a)* b)$ is a pre-Lie algebra?

Comment of 2025: If $2\equiv \xi ^{p^{n-1}}$ when $\xi $ is a primitive root modulo p, and if A is strongly nilpotent of nilpotency index less than p, then the result follows by (A. Smoktunowicz, *Adv. Math.*, **409**, part B (2022), 108683). It is not known if the result follows when A is not strongly nilpotent. b) Let k be a natural number, and let p be a prime number such that $p>2^{k}$. Is there a bijective correspondence between $\mathbb{F}_{p}$-braces of cardinality p^{k} and left nilpotent pre-Lie algebras over ${\mathbb{F}}_{p}$ of cardinality p^{k}?

An affirmative answer to any of the above questions would have consequences for the theory of set-theoretic solutions of the Yang--Baxter equation and for the theory of Hopf--Galois extensions.

Let G be a finite group and p be a prime. Let $\Psi_{p,G}$ be the class function of G which vanishes on all p-singular elements of G and whose value at each p-regular element x of G is the number of p-elements of $C_G(x)$.

(a) Is it true that $\Psi_{p,G}$ is a character of G?

(b) If yes, can $\Psi_{p,G}$ be afforded by a projective RG-module, where R is a complete discrete valuation ring of characteristic zero such that the field of fractions of R is a splitting field for G and its subgroups, and the residue field $R/J(R)$ is a splitting field of characteristic p for G and its subgroups?

Let p be a prime number. A group Γ is called p-Jordan if there exist constants J and e such that any finite subgroup $G\subset\Gamma$ contains a normal abelian subgroup of order coprime to p and of index at most $J\cdot |G(p)|^e$. (For example by the results of Brauer--Feit and Larsen--Pink, for any field K of characteristic p the group $\operatorname{GL}_n(K)$ is p-Jordan with $e=3$.) Let the p-Jordan exponent $e(\Gamma)$ of the group Γ be the infimum of all constants e for which the above bound holds for some constant $J=J(e)$.

a) Is it true that this infimum is always attained?

b) Is it true that $e(\Gamma)\leqslant 3$ for any p-Jordan group Γ?

Let p be a prime and let G be a pro-p group. Suppose that all of the (continuous Galois) cohomology groups $H^n(G,\mathbb F_p)$ of G with coefficients in the field of p elements are finite. Does it necessarily follow that the cohomology ring $H^*(G,\mathbb F_p)$ is finitely generated?

O / open | Kourovka 群论问题集

Let G be a finitely generated group with a fixed finite generating set S and the corresponding word metric $L_S(*)$. An element g is said to be distorted in G if $L_S(g^n)/n\to 0$ as $n\to\infty$; this notion is independent of the choice of the generating set S. For any, not necessarily finitely generated, group H, an element $g\in H$ is said to be distorted if there is a finitely generated subgroup G of H containing g in which g is distorted. Do there exist finitely generated left-orderable groups in which every nontrivial element is distorted?

S / solved | Kourovka 群论问题集

As in 17.57, let $r(m)=\{r+km\mid k\in\mathbb Z\}$ for integers $0\leqslant r<m$; for $r_1(m_1)\cap r_2(m_2)=\emptyset$ let the class transposition $\tau_{r_1(m_1),r_2(m_2)}$ be the involution which interchanges r_1+tm_1 and r_2+tm_2 for each integer t and fixes everything else, and let $\operatorname{CT}(\mathbb Z)$ be the group generated by all class transpositions. Let CT_k be the subgroup of $\operatorname{CT}(\mathbb Z)$ generated by the class transpositions $\tau_{r_1(k),r_2(k)}$ for $0\leqslant r_1\ne r_2<k$. Since $\tau_{r_1(k),r_2(k)}$ permutes the residue classes modulo k, the group CT_k is isomorphic to the symmetric group S_k. Let $\operatorname{CT}(k)=\langle\operatorname{CT}_2,\operatorname{CT}_3,\ldots,\operatorname{CT}_k\rangle$. Is it true that for $k>3$ the group $\operatorname{CT}(k)$ is isomorphic to the symmetric group S_N, where N is the least common multiple of the numbers $2,3,\ldots,k$?

Let Γ be a finite simple group and let $N_n(\Gamma)$ denote the set of normal subgroups of the free group F_n of rank n whose quotient is isomorphic to Γ.

Conjecture: $\operatorname{Aut}(F_n)$ acts transitively on $N_n(\Gamma)$ for $n\geqslant 3$.

For $\sigma\in S_n$ and $\tau\in S_m$, where $n\leqslant m$, let $d_n^{\mathrm{flex}}(\sigma,\tau)=(1/n)\cdot(|\{x\in\{1,\ldots,n\}\mid \sigma(x)\ne\tau(x)\}|+(m-n))$. An almost-homomorphism $\{f_n\}$ is said to be flexibly close to a homomorphism if there is a sequence of group homomorphisms $\rho_n:G\to S_{m_n}$ with $n\leqslant m_n$ such that $d_n^{\mathrm{flex}}(\rho_n(g),f_n(g))\to 0$ as $n\to\infty$ for all $g\in G$. The group G is said to be flexibly permutation stable if every almost-homomorphism of G is flexibly close to a homomorphism. Is $\operatorname{SL}_n(\mathbb Z)$ flexibly permutation-stable?
