The Gruenberg--Kegel graph (or the prime graph) GK(G) of a finite group G is a labelled graph with vertex set consisting of all prime divisors of the order of G in which different vertices p and q are adjacent if and only if G contains an element of order pq. Let GK(G) denote the abstract graph obtained from GK(G) by removing all labels. A finite group G is said to be recognizable by the isomorphism type of its Gruenberg--Kegel graph if there are no finite groups H $\ncong$ G with GK(H) isomorphic to GK(G). Are there infinitely many (pairwise non-isomorphic) finite groups which are recognizable by the isomorphism type of the Gruenberg--Kegel graph?

For what natural numbers n does the following equality hold: $$GL_n({\mathbb{R})=D_n({\mathbb{R})\cdot O_n({\mathbb{R})\cdot UT_n({\mathbb{R})\cdot GL_n({\mathbb{Z})? $$ For notation, see, for instance, (M. I. Kargapolov, Ju. I. Merzljakov, *Fundamentals of the Theory of Groups*, Springer, New York, 1979). For given n this equality implies the affirmative solution of Minkowski's problem on the product of n linear forms (A. M. Macbeath, *Proc. Glasgow Math. Assoc.*, **5**, no. 2 (1961), 86--89), which remains open for $n \geq 6$. It is known that the equality holds for $n \leq 3$ (Kh. N. Narzullayev, *Math. Notes*, **18** (1975), 713--719); on the other hand, it does not hold for all sufficiently large n (N. S. Akhmedov, *Zapiski Nauchn. Seminarov LOMI*, **67** (1977), 86--107 (Russian)).

Let k be a field of characteristic different from 2, and G_k the group of transformations $A = (a, \alpha) : x \rightarrow ax +\alpha$ \ ($a, \alpha \in k$, \ $a\ne 0$). Extend G_k to the projective plane by adjoining the symbols $ (0, \alpha)$ and a line at infinity. Then the lines are just the centralizers $C_G(A)$ of elements $A\in G_k$ and their cosets. Do there exist other groups G complementable to the projective plane such that the lines are just the cosets of the centralizers of elements of G?

(Y. Ihara). Consider the quaternion algebra Q with norm $f=x^2 - \tau y^2 - \rho z^2 + \rho \tau u^2$, $\rho , \tau \in {\mathbb{Z}}$. Assume that f is indefinite and of ${\mathbb{Q}}$-rank 0, i. e. $f=0$ for $x,y,z,u \in {\mathbb{Q}}$ implies $ x=y=z=u=0$. Consider Q as the algebra of the matrices $$X=\left(\!\!\begin{array}{cc}x+\sqrt{\tau}y&\rho (z+\sqrt{\tau }u)\cr z-\sqrt{\tau}u&x-\sqrt{\tau}y\end{array}\!\!\right)$$ with $x,y,z,u \in {\mathbb{Q}}$. Let p be a prime, $p\nmid \rho \tau$. Consider the group G of all X with $x,y,z,u \in {\mathbb{Z}^{(p)}}$, $\mathrm{det} X=1$, where ${\mathbb{Z}^{(p)}=\{ m/p^t\mid m,t \in {\mathbb{Z}}\} $.

Conjecture: G has the congruence subgroup property, i. e. every non-central normal subgroup N of G contains a full congruence subgroup $N({\mathfrak{A}})=\{ X \in G\mid X \equiv E (\mathrm{mod} {\mathfrak{A}})\} $ for some ${\mathfrak{A}}$. Notice that the congruence subgroup property is independent of the matrix representation of Q.

Let ${\mathfrak{L}}$ be the class of locally compact groups with no small subgroups (see D. Montgomery, L. Zippin, *Topological transformation groups*, New York, 1955; V. M. Glushkov, *Uspekhi Matem. Nauk*, **12**, no. 2 (1957), 3--41 (Russian)). Study extensions of groups in this class with the objective of giving a direct proof of the following: For each $G \in {\mathfrak{L}}$ there exists an $H \in {\mathfrak{L}}$ and a (continuous) homomorphism $\vartheta \!:G \rightarrow H$ with a discrete kernel and an image $\mathrm{Im} \vartheta$ satisfying $\mathrm{Im} \vartheta \cap Z(H)=1$ ($Z(H)$ is the center of H). This result follows from the Gleason--Montgomery--Zippin solution of Hilbert's 5th Problem (since ${\mathfrak{L}}$ is the class of finite-dimensional Lie groups and the latter are locally linear). On the other hand a direct proof of this result would give a substantially shorter proof of the 5th Problem since the adjoint representation of H is faithful on $\mathrm{Im} \vartheta$.

Kourovka Notebook Problem 7.25

O / open | Kourovka 群论问题集

We associate with words in the alphabet x, x^{-1}, y, y^{-1}, z, $z^{-1},\ldots $ operations which are understood as functions in variables $x, y, z,\ldots $. We say that a word A *is expressible in words $B_1,\ldots ,B_n$ on the group G* if A can be constructed from the words $B_1,\ldots ,B_n$ and variables by means of finitely many substitutions of words one into another and replacements of a word by another word which is identically equal to it on G. A list of words is said to be *functionally complete on G* if every word can be expressed on G in words from this list. A word B is called a *Schaeffer word on G* if every word can be expressed on G in B (compare with A. V. Kuznetsov, *Matem. Issledovaniya*, Kishin\"ev, **6**, no. 4 (1971), 75--122 (Russian)). Does there exist an algorithm which decides

a) by a word B, whether it is a Schaeffer word on every group? Compare with the problem of describing all such words in (A. G. Kurosh, *Theory of Groups*, Moscow, Nauka, 1967, p. 435 (Russian)); here are examples of such words: xy^{-1}, $x^{-1}y^2z$, $x^{-1}y^{-1}zx$.

b) by a list of words, whether it is functionally complete on every group?

c) by words $A, B_1,\ldots ,B_n$, whether A is expressible in $ B_1,\ldots ,B_n$ on every group? (This is a problem from A. V. Kuznetsov, *ibid.*, p. 112.)

d) the same for every finite group? (For finite groups, for example, x^{-1} is expressible in xy.) For a fixed finite group an algorithm exists (compare with A. V. Kuznetsov, *ibid.*, $\S$ 8).

(B. Amberg). Does a group satisfy the minimum (respectively, maximum) condition on subgroups if it is a product of two subgroups satisfying the minimum (respectively, maximum) condition on subgroups?

问题集入口：https://kourovkanotebookorg.wordpress.com/

04790 | KOU-7.57

Kourovka Notebook Problem 7.57

P / partially_solved | Kourovka 群论问题集

a) A set of generators of a finitely generated group G consisting of the least possible number $d(G)$ of elements is called a *basis of G*. Let $r_M(G)$ be the least number of relations necessary to define G in the basis M and let $r(G)$ be the minimum of the numbers $r_M(G)$ over all bases M of G. It is known that $r_M(G) \leq d(G) + r(G)$ for any basis M. Does there exist a finitely presented group G for which the inequality becomes equality for some basis M?

[Archived solved part(s) of 7.57:] A set of generators of a finitely presented group G that consists of the least possible number $d(G)$ of generators is called a *basis* for G. Let $r_M(G)$ be the least number of relations necessary to define G in the basis M, and $r(G)$ the minimum of $r_M(G)$ over all bases M for G. Let G_1, G_2 be any non-trivial groups.

b) Is it true that $r_{M_1\cup M_2}(G_1*G_2)= r_{M_1}G_1+r_{M_2}(G_2)$ for any bases M_1, M_2 of G_1, G_2, respectively?

c) Is it true that $r(G_1*G_2)=r(G_1)+r(G_2)$?

Kourovka Notebook Problem 7.58

O / open | Kourovka 群论问题集

Suppose that F is an absolutely free group, R a normal subgroup of F, and let ${\mathfrak{V}}$ be a variety of groups. It is well-known (H. Neumann, *Varieties of Groups*, Springer, Berlin, 1967) that the group $F/{\mathfrak{V}}(R)$ is isomorphically embeddable in the ${\mathfrak{V}} $-verbal wreath product of a ${\mathfrak{V}} $-free group of the same rank as F with F/R. Find a criterion indicating which elements of this wreath product belong to the image of this embedding. A criterion is known in the case where ${\mathfrak{V}}$ is the variety of all abelian groups (V. N. Remeslennikov, V. G. Sokolov, *Algebra and Logic*, **9**, no. 5 (1970), 342--349).

Kourovka Notebook Problem 8.3

O / open | Kourovka 群论问题集

Let m and n be positive integers and p a prime. Let $P_n({\mathbb{Z}_{p^m})$ be the group of all $n \times n$ matrices (a_{ij}) over the integers modulo p^m such that $a_{ii} \equiv 1$ for all i and $a_{ij} \equiv 0 (\mathrm{mod} p)$ for all $i > j$. The group $P_n({\mathbb{Z}_{p^m})$ is a finite p-group. For which m and n is it regular?

Editors' comment (2001): The group $P_{n}({\mathbb{Z}_{p^m})$ is known to be regular if $mn<p$ (Yu. I. Merzlyakov, *Algebra i Logika*, **3**, no. 4 (1964), 49--59 (Russian)). The case $m=1$ is completely done by A. V. Yagzhev in (*Math. Notes*, **56**, no. 5--6 (1995), 1283--1290), although this paper is erroneous for $m>1$. The case $m=2$ is completed in (S. G. Kolesnikov, *Issledovaniya in analysis and algebra*, no. 3, Tomsk Univ., Tomsk, 2001, 117--125 (Russian)). *Editors' comment (2009):* The group $P_{n}({\mathbb{Z}_{p^m})$ was shown to be regular for any m if $n^2<p$ (S. G. Kolesnikov, *Siberian Math. J.*, **47**, no. 6 (2006), 1054--1059).

04908 | KOU-9.39

Kourovka Notebook Problem 9.39

O / open | Kourovka 群论问题集

Let Ω be a countable set and ${\mathfrak{m}}$ a cardinal number such that $\aleph _0 \leq {\mathfrak{m}} \leq 2^{\aleph _0}$ (we assume Axiom of Choice but not Continuum Hypothesis). Does there exist a permutation group G on Ω that has exactly ${\mathfrak{m}}$ orbits on the power set ${\mathfrak{P}}(\Omega)$?

Comment of 2001: It is proved (S. Shelah, S. Thomas, *Bull. London Math. Soc.*, **20**, no. 4 (1988), 313--318) that the answer is positive in set theory with Martin's Axiom. The question is still open in ZFC.

Kourovka Notebook Problem 9.43

P / partially_solved | Kourovka 群论问题集

b) The group G indicated in (N. D. Podufalov, *Abstracts of the 9th All--Union Symp. on Group Theory*, Moscow, 1984, 113--114 (Russian)) allows us to construct a projective plane of order 3: one can take as lines any class of subgroups of order $2\cdot 5\cdot 11\cdot 17$ conjugate under $ S$ and add four more lines in a natural way. In a similar way, one can construct projective planes of order p^n for any prime p and any natural $ n$. Could this method be adapted for constructing new planes?

[Archived solved part(s) of 9.43:] a) The group G described in the solution of 8.73 (Archive) enables us to construct a projective plane of order 3 in which the lines are the elements of any conjugacy class of subgroups of order $2\cdot 5\cdot 7\cdot 11$ together with four lines added in a natural way. In a similar way, we can construct a projective plane of order p^n for any prime p and any positive integer n. Does the resulting projective plane have the Galois property?

04963 | AIM-GEOMETRIC_GROUP_THEORY-0157

Large-group transfer and parity obstructions for power quotients of Out(F_n)

P / partially_solved | AIM 研讨会问题汇编

Reconstructed Problem 3.6. Does there exist a positive integer \(p\) such that \[B_p(\operatorname{Out}(F_n)):= \operatorname{Out}(F_n)/ \left\langle\!\left\langle\gamma^p: \gamma\in\operatorname{Out}(F_n)\right\rangle\!\right\rangle \] is infinite?

The PDF itself, not merely the JSON extraction, prints \[\text{“Does there exist }p\to0\text{ such that } \operatorname{Out}(F_n)/\langle\!\langle\gamma^p\rangle\!\rangle, \text{ all }\gamma\in\operatorname{Out}(F_n),\text{ is infinite?”} \] The superscript \(p\), the double normal-closure brackets, and the scope “all \(\gamma\in\operatorname{Out}(F_n)\)” are visible in the PDF. Thus the intended denominator is \[\left\langle\!\left\langle \gamma^p\mid\gamma\in\operatorname{Out}(F_n) \right\rangle\!\right\rangle. \] It is nevertheless not meaningful after the existential quantifier if \(p\) is an integer exponent. Taking \(p=0\) would make every relator \(\gamma^0=1\), leave \(\operatorname{Out}(F_n)\) unchanged, and fail to address the preceding sentence, which asks for an infinite torsion quotient. The source therefore contains an unresolved typo.

The mathematically coherent reconstruction used here is:

This is the maximal quotient of \(\operatorname{Out}(F_n)\) of exponent dividing \(p\), a Burnside-type quotient. Two plausible stronger repairs are “\(p\gg0\)” and “as \(p\to\infty\).” The results below also give infinitely many exponents in ranks two and three, so they address those readings partially. The literal printed reading has no nontrivial mathematical content and is not silently adopted.

Largeness of Out(F_n): complete rank classification and quantitative transfer consequences

P / partially_solved | AIM 研讨会问题汇编

Problem 3.5. Does there exist a finite-index subgroup \(\Gamma < \operatorname{Out}(F_n)\) such that \(\Gamma \to F_2\)?

It then records discussion about applicable techniques, train tracks, an infinite torsion quotient, non-bounded generation, and bounded cohomology.

Immediately before Problem 3.5 it says: “if \(n\ge4\), is \(\operatorname{Out}(F_n)\) large? Meaning, does there exist a finite-index subgroup which acts on a tree, thus maps onto a free group?” Therefore:

- the intended rank range is \(n\ge4\); - \(F_2\) is the nonabelian free group of rank two; - the arrow is intended to be an **epimorphism**, so the reconstructed formula is \(\Gamma\twoheadrightarrow F_2\).

This is the standard definition that \(\operatorname{Out}(F_n)\) is **large**. The phrase about acting on a tree is motivation, not a general equivalence: an epimorphism to \(F_2\) gives an action on its Cayley tree, but an arbitrary nontrivial tree action need not produce a free quotient.

Largest actions from universally elliptic Deligne stabilizers

P / partially_solved | AIM 研讨会问题汇编

Is there a ``largest'' acylindrically hyperbolic space on which these Artin groups act that sees all loxodromic elements?

The exact AIM record asks:

It is Problem 4.5 in the “Non-positive curvature” section of the AIM workshop list *Geometry and topology of Artin groups*. The immediately preceding records ask whether all irreducible nonspherical Artin groups are acylindrically hyperbolic and ask for a description of the hyperbolic space. Thus the broad reading concerns irreducible nonspherical Artin groups for which acylindrical hyperbolicity is known or expected.

There are two notions in the question that must be separated. In the terminology now standard after Abbott--Balasubramanya--Osin (ABO), “largest” means largest in the domination poset of **cobounded** acylindrical actions. “Sees all loxodromic elements” means **universal**: every element that is loxodromic in some acylindrical action is loxodromic in the chosen action. A largest action is universal, but universality alone does not prove largestness.

The broad Artin-group question remains beyond what is proved here. The main result below gives a positive answer, with an explicit natural space, for the two-dimensional hyperbolic-type class studied by Martin--Przytycki under their finite-neighbor hypothesis.

No atomless invariant measure on the perfect kernel of Sub(F)

S / solved | AIM 研讨会问题汇编

Is there an invariant \emph{continuous} probability measure for the action of \(F\) acting on its perfect kernel (by conjugation)?

The record is Problem 1.6 in the workshop section *Thompson group F and groups of homeomorphisms of the interval and the circle*. The immediately preceding Problem 1.5 defines transfinite Cantor--Bendixson derivatives and asks for the Cantor--Bendixson rank of the space of subgroups of \(F\). This fixes the intended object: “its perfect kernel” means the Cantor--Bendixson perfect kernel \[P\subseteq \operatorname{Sub}(F), \] not the derived group \(F'\), despite the fact that \(F'\) is itself a perfect group.

In this descriptive/topological setting, a *continuous probability measure* means an atomless (nonatomic) Borel probability measure: \(\mu(\{H\})=0\) for every subgroup \(H\). It cannot mean merely a measure defining a continuous functional on continuous functions, since every Borel probability on a compact metrizable space does so and a Dirac mass at an invariant subgroup would make the question trivial. “A measure on \(P\)” is taken to mean \(\mu(P)=1\), not that its topological support must equal all of \(P\). The negative result below is stronger and therefore also rules out the full-support version.

The current AIM workshop page still identifies the September 2016 workshop and links to its open-problem list.

Under this reconstruction, the answer is **no**.

Quantitative higher-commutator tails and an RD window for return probabilities

P / partially_solved | AIM 研讨会问题汇编

I checked the AIM source and recovered the following five questions.

Let \(\Gamma\) be a discrete group with a proper length function \(L\), let \[D\delta_g=L(g)\delta_g\qquad(g\in\Gamma), \] and let \(\tau\) be the canonical trace on \(C_r^*(\Gamma)\).

1. For which groups is \[\mathcal L=\{a\in C_r^*(\Gamma):\tau(a)=0,\ \|[D,a]\|\leq 1\} \] norm precompact? Rieffel's criterion says this is equivalent to the associated Connes metric inducing the weak-* topology on the state space. The source records the affirmative results for \(\mathbb Z^d\) and hyperbolic groups and asks particularly about RD groups. It also records Antonescu--Christensen's result that, for an RD group, the analogous ball \(\mathcal L_k\), defined using the \(k\)-fold commutator with \(D\), is precompact for all sufficiently large \(k\). 2. For which groups does Roe's equality \[C_r^*(\Gamma)=C_u^*(|\Gamma|)\cap L(\Gamma) \tag{ITAP} \] hold? Here \(C_u^*(|\Gamma|)\) is the uniform Roe algebra and \(L(\Gamma)\) is the group von Neumann algebra. The source observes that a Haagerup-style argument proves this when \(\Gamma\) has RD for a conditionally negative length. 3. Prove Kaplansky's zero-divisor conjecture, \(\mathbb C\Gamma\) is a domain for torsion-free finitely generated \(\Gamma\), under the additional hypothesis RD. 4. If \(\nu\) is a finitely supported symmetric probability measure, is \[\nu^{*(2n)}(e)\sim c(\nu)n^{-d(\nu)}\rho^{2n}, \tag{RW} \] where \(\rho\) is the spectral radius of convolution by \(\nu\) on \(\ell^2(\Gamma)\)? 5. Is there a relation between RD and entropy of ergodic actions?

P / partially_solved | AMR 问题清单汇编

(Swarup) Suppose G is a hyperbolic group which is a graph of hyperbolic groups such that all edge-to-vertex inclusions are quasi-isometric embeddings. Mitra shows that each vertex-group inclusion $V\hookrightarrow G$ induces a continuous Cannon-Thurston map $\partial V\to\partial G$. Describe its point-preimages; in particular, show that the map is finite-to-one.

(Swarup) Suppose G is a 1-ended finitely presented group that acts on a compact connected metric space X as a convergence group. What can be said about G if X has cut points? Does X have to be locally connected? The model theorem of Bowditch [Bow99] and Swarup [Swa96] says that if G is word hyperbolic, then X is locally connected and doesn’t have cut points. In another interesting case, when G is a geometrically finite Kleinian group and X its limit set, cut points can arise, for example if G splits over a parabolic subgroup.

05181 | AIM-GEOMETRIC_GROUP_THEORY-0029

Rank obstruction and a characteristic-fiber normalizer reduction

P / partially_solved | AIM 研讨会问题汇编

A group \(G\) is said to be of type \(VF\) if there exists a finite index subgroup \(G'\) of \(G\) which admits a finite classifying space.

If \(G\) is a free-by-cyclic group then \(\operatorname{Out}(G)\) is of type \(VF\).

The repository record itself is uncorrupted. More importantly, the workshop literature fixes the convention: a free-by-cyclic group is \[G=F_n\rtimes_\phi\mathbb Z \] with \(F_n\) of **finite rank** and the quotient infinite cyclic. Andrew--Martino use exactly this convention in the first sentence of their setup. Thus the intended conjecture concerns finite \(n\). If arbitrary-rank free fibers are allowed, the assertion is false (Proposition 5.1 below).

We use the presentation \[G_\phi=\langle F_n,t\mid txt^{-1}=\phi(x)\ (x\in F_n)\rangle \] and write \(\Phi=[\phi]\in\operatorname{Out}(F_n)\).

05183 | AIM-GEOMETRIC_GROUP_THEORY-0007

Rank-two verification and peripheral reductions for the relatively hyperbolic LERF conjecture

P / partially_solved | AIM 研讨会问题汇编

Relatively hyperbolic case. If \(G\) is a LERF relatively hyperbolic free-by-cyclic group which is not hyperbolic then \(G\) is the fundamental group of a hyperbolic 3-manifold.

Here “hyperbolic” in the hypothesis means word-hyperbolic, while “hyperbolic 3-manifold” in the conclusion means a manifold with a complete hyperbolic metric.

The workshop report supplies important intended context: it discusses free-by-cyclic groups hyperbolic relative to a **nonempty collection of \(\mathbb Z^2\) subgroups**, and identifies such groups as analogues of cusped finite-volume hyperbolic 3-manifold groups. Accordingly, throughout the mathematical results below, “relatively hyperbolic” means non-elementary strong relative hyperbolicity with respect to a finite nonempty family of proper subgroups isomorphic to \(\mathbb Z^2\). This convention is necessary: allowing the degenerate structure relative to the group itself would make the statement ill-posed. The intended conclusion is a finite-volume cusped hyperbolic 3-manifold. The source does not specify orientability, so none is silently imposed.

Write \[G_\phi=F_n\rtimes_\phi\mathbb Z =\langle F_n,t\mid txt^{-1}=\phi(x),\ x\in F_n\rangle, \] where \(\Phi=[\phi]\in\operatorname{Out}(F_n)\). The exact conclusion is an isomorphism \(G_\phi\cong\pi_1(M)\), not merely a virtual identification.

05190 | AIM-GEOMETRIC_GROUP_THEORY-0164

Recovering indecomposable vertex blocks from dual laminations

P / partially_solved | AIM 研讨会问题汇编

Relate a fine/graph-of-actions decomposition theory for \(F_N\)-trees to the tree's dual algebraic lamination, in both directions, and relate both descriptions to finite systems of partial isometries.

It contains the same unexplained string "GL-theory," the same conspicuous capitalization "FINE DECOMPOSITION," and the same horofunction prose. Three source-recovery conclusions are important.

1. **"GL" is not expanded in the source.** In the relevant literature it is genuinely ambiguous. Gaboriau--Levitt is the standard author pair behind the geometric index and a finite-tree/partial-isometry construction [GL95]. Guirardel--Levitt is another standard "GL" author pair in the Outer-space and JSJ literature, while Guirardel introduced the indecomposability notion used in later decomposition results. The exact phrase "fine decomposition" was not found as a named theorem in the primary sources checked. Later papers instead speak of Levitt's graph-of-actions or Levitt decomposition, transverse families, indecomposable trees, compact hearts, and Rips or splitting induction. Because the source itself does not decide between these usages, this report does not silently expand "GL." The strongest contextual evidence for the initials alone is Gaboriau--Levitt: [GL95] both has the conventional citation key GL and directly treats geometric index and systems of partial isometries. The decomposition language, however, is closer to Levitt's graph-of-actions theory and Guirardel's refinements. "FINE DECOMPOSITION" is therefore treated as unresolved workshop shorthand or an editorial placeholder, not as a verified proper noun.

2. **The horofunction paragraph introduces Problem 5.3.** The paragraph changes topic immediately after Problem 5.2 and defines the object whose closure is asked for in the next numbered problem: "Problem 5.3. What is the closure \(X\)? What is \(X\setminus X\), the horofunction boundary ...?" It is transitional prose for 5.3, not an additional clause of Problem 5.2.

3. **The mathematical reconstruction of its OCR is** \[x\longmapsto [d(\,\cdot\,,x)]\in C^0(X_n)/\mathbb R, \qquad f\sim g\iff f-g\text{ is constant}, \] with uniform convergence on compact sets. Thus "7 →" is a broken \(\mapsto\) glyph, \(C0\) is \(C^0\), and "homotopy to a constant" must be corrected to "differ by an additive constant." This is a mathematically compelled reconstruction, not literal source text. It is not used below because it belongs with Problem 5.3.

Accordingly, the recovered Problem 5.2 is the broad comparison problem:

05195 | AIM-GEOMETRIC_GROUP_THEORY-0136

Regularized determinant approximation and the zero-spectrum obstruction

P / partially_solved | AIM 研讨会问题汇编

The following is equivalent to the previous problem.

Let $A\in M_l(\mathbb{Z} \Gamma)$, denote $A_k=A/\Gamma_k$. Is it true that $$tr_{L\Gamma}(\log A^*A)=\lim \frac{tr(\log A_k^*A_k)}{|\Gamma:\Gamma_k|}?$$

Its exact problem text is:

The adjacent Problem 11.2 asks whether normalized Ray--Singer torsions of a tower $M_k=\widetilde M/\Gamma_k$ converge to the analytic L^2-torsion of $\widetilde M$. Thus the intended standing assumptions are a decreasing normal finite-index chain \[\Gamma=\Gamma_0\supseteq\Gamma_1\supseteq\cdots, \qquad \bigcap_k\Gamma_k=\{e\}, \] and $q_k=[\Gamma:\Gamma_k]$.

The notation A/Γ_k means entrywise application of $\mathbb Z\Gamma\to\mathbb Z[\Gamma/\Gamma_k]$.

There is one essential convention missing from the displayed formula. The ordinary functional-calculus logarithm has $\log 0=-\infty$, whereas torsion uses the **regular Fuglede--Kadison determinant**, i.e. the logarithmic integral over the positive spectrum with the kernel deleted. With a literal logarithm the displayed assertion is false (and often not a finite equality); with the regular/pseudodeterminant convention it is the standard determinant approximation conjecture.

Restriction Criteria for Endotrivial Modules

P / partially_solved | Oberwolfach 报告问题汇编

Let S be a Sylow p-subgroup of a finite group G and define $\rho_1(Q)=N_G(Q)'$ and $\rho_i(Q)=\langle N_G(Q)\cap\rho_{i-1}(R):1\ne R\subseteq S\rangle$, with $\rho^\infty(S)=\bigcup_i\rho_i(S)$. The conjecture is that a one-dimensional $kN_G(S)$-module L is the restriction, modulo projectives, of an endo-trivial kG-module if and only if $\rho^\infty(S)\subseteq\ker L$; equivalently, the image of $K(G)\to K(N_G(S))$ is the dual of $N_G(S)/\rho^\infty(S)$.

Stabilizer lengths and rapid decay for tree and hyperbolic-graph actions

P / partially_solved | AIM 研讨会问题汇编

This record is the four-question list in Section 5, “RD for groups acting on special metric spaces,” of the AIM workshop notes *The property of rapid decay*.

1. In the \(\widetilde A_2\)-building setting of RRS, for \(g\) supported on elements of shape \((m,n)\), their estimate is \[\|f*g\|_2\le p(m,n)\|f\|_2\|g\|_2, \qquad p(m,n)=\frac12(m+1)(n+1)(m+n+2)\sqrt{\max\{m,n\}+1}. \] Is the square-root factor necessary? 2. Does Wise's non-Hopfian group have property RD? The presentation intended in the source is \[W=\langle a,b,s,t\mid [a,b]=1,\; sas^{-1}=(ab)^2,\;tbt^{-1}=(ab)^2\rangle . \] 3. If \(\Gamma\) acts on a simplicial tree, what hypotheses on vertex and edge stabilizers characterize property RD? The workshop notes suggest RD of stabilizers for the lengths induced from \(\Gamma\), with HNN extensions as an intended application. 4. Can the tree be replaced by a bounded-degree \(\delta\)-hyperbolic graph?

The equivalent five-generator presentation used by Barré--Pichot is \[\langle a,b,c,s,t\mid c=ab=ba,\;c^2=sas^{-1}=tbt^{-1}\rangle . \] Changing both stable letters to their inverses accounts for the opposite conjugation convention sometimes seen in print.

The forward Lipschitz horoboundary and a rose-face orientation test

P / partially_solved | AIM 研讨会问题汇编

Problem 5.3. What is the closure X? What is X\X, the horofunction boundary of outer space in the Lipschitz metric?

Thierry Coulbois asked if we know the horofunction boundary in the simplicial metric, and also if it is reasonable Busemann points could be the whole thing. For the latter, Cormac said yes, as it is true for Teichmüller space. Specifically, a Busemann point \(B_\sigma\) is determined by a 'good' ray

\(\sigma:[0,\infty)\to X_n\) by \(B_\sigma(x)=\lim_{n\to\infty}(d(x,\sigma(n))-n)\). If \(X\) were CAT(0) or Teichmüller space 6 EDITED BY JOHANNA MANGAHAS

with the Lipschitz metric, then X\X would consist entirely of Busemann points. However, warned Cormac, even for normed spaces you can get points that are not Busemann points.

05274 | AIM-GEOMETRIC_GROUP_THEORY-0061

The positive-suffix order is a lattice exactly in spherical type

S / solved | AIM 研讨会问题汇编

Nearby items do not define a special group \(A\), and the page has no hidden introduction or attribution. The natural reconstruction is therefore that \(A=A_S\) is a finite-rank Artin group with its standard generating set \(S\), and “positive word” means an element of the standard Artin monoid \(M=A_S^+\).

Two ambiguities materially change the answer.

1. The empty word must be allowed. If “positive” means nonempty, then \(a\nleq a\) for every \(a\), so the relation is not reflexive and cannot define a join-semilattice. Standard monoid usage includes the empty word, representing \(1\); that is the convention used below. 2. The recorded domain is the group \(A\), not the monoid \(A^+\). On \(A^+\) the answer is always yes, by positive-monoid gcds. On the whole group the answer is yes exactly in spherical type.

The issue is under-specification, not damaged text.

05275 | AIM-GEOMETRIC_GROUP_THEORY-0108

The solved volume exponent of the first Grigorchuk group

S / solved | AIM 研讨会问题汇编

Does the limit \[\lim_{n\rightarrow\infty} \frac{\log \log (B_G(n))}{\log n} \] exist for the Grigorchuk group?

The notation requires recovery. A Wayback Machine snapshot of the actual AIM page dated 2023-12-08 contains the same TeX source `\log \log (B_G(n))`; there are no absolute-value bars in that archived HTML. On the other hand, a logarithm cannot be applied to a set. The immediately preceding AIM item writes $B_n(e)$ for a ball, while the standard scalar object in the literature is the volume growth \[v_{G,S}(n)=|B_{G,S}(n)|=\#\{g\in G:|g|_S\le n\}. \] The only mathematically coherent recovery is therefore \[\lim_{n\to\infty}\frac{\log\log |B_{G,S}(n)|}{\log n}. \tag{1.1} \]

The singular phrase “the Grigorchuk group,” together with the neighboring problems' notation G, means the **first Grigorchuk group** \[G=G_{(012)^\infty} \] with the canonical tree-automorphism generators $S=\{a,b,c,d\}$. This is also exactly the convention in Erschler--Zheng. The AIM record does not state S; Section 7 proves that the limit and its value are independent of the choice of finite generating set, so this omission does not affect the final answer.

A block formula and Morse-potential computation for compact monotone Fukaya categories

P / partially_solved | AIM 研讨会问题汇编

“Same questions as above for \(Fuk(X)\) where \(X\) is compact symplectic.”

Recovered question. For a well-defined split-closed derived Fukaya category of a compact symplectic manifold \(X\), determine its Rouquier dimension and its full Orlov spectrum, including the occurrence and size of gaps and consecutive sequences.

- 7.1: “What can be said about the Orlov spectrum of a toric variety (or any \(X\))? (e.g. about gaps, sequences, etc.)” - 7.2: “What about Rouquier dimension or Orlov spectrum of \(D^b(\operatorname{Sing}(X)) = D^b(\operatorname{Coh}(X))/D^b(\operatorname{Perf}(X))\)?”

Thus the conservative recovery of 7.3 is:

It takes from 7.1 and 7.2 only the explicitly shared invariants, Rouquier dimension and Orlov spectrum.

A boundary-frontier sieve for virtually abelian moduli bases

P / partially_solved | AIM 研讨会问题汇编

Problem 2.1 (Viehweg). Let \(M_H\) denote a moduli stack of canonically polarized manifolds. Can \(\pi_1(M_H)\) be almost abelian (almost abelian means having an abelian subgroup of finite index)? More precisely, if \(U\) is a nonsingular variety (not a point) mapping generically finitely to the moduli stack, can \(\pi_1(U)\) be almost abelian. The conjecture is no. The result is known for \(M_g\), and can be verified whenever some sort of local Torelli theorem holds. A \(U\) as above cannot be the complement in \(\mathbb P^n\) of a normal crossings divisor with fewer than \(n\) components. At present this is only known if the number of components of \(H\) is strictly smaller than \(n\) (see [VZ02]). The following two questions are motivated by work of Viehweg and Zuo [VZ02] and [VZ05].

A coefficient-ring shadow and coherence obstruction for the Pin(2)-Q8 Tate model

P / partially_solved | AIM 研讨会问题汇编

Equip \(\mathrm{Pin}(2)\) (resp. \(Q_8\)) with the canonical \(\mathbb Z/2\)-action (resp. the action given by conjugation by \(i\)). Then the \(E_\infty\)-map \[L^s(\mathbb Z)_{(2)}\longrightarrow L^n(\mathbb Z) \] can be identified by taking strict \(\mathbb Z/2\)-fixed points of the inclusion-induced map \[\mathbb Z_{(2)}^{t\mathrm{Pin}(2)}\longrightarrow \mathbb Z^{tQ_8}. \]

This is Conjecture 2.9, “\(L\)-theory of integers,” from the AIM workshop *Equivariant techniques in stable homotopy theory* (October 2022).

Write \[P=\mathrm{Pin}(2)=S^1\cup jS^1\subset \mathbb H^\times, \qquad Q=Q_8=\{\pm1,\pm i,\pm j,\pm k\}, \] and let \(C=\langle\tau\rangle\cong C_2\) act by \(\alpha=c_i\), conjugation by \(i\). This fixes \(S^1\), sends \(jz\) to \(-jz\), has order two because \(i^2=-1\) is central, and restricts to the stated action on \(Q\). For an extension \(1\to K\to K\rtimes_\alpha C\to C\to1\), the parametrized Tate construction produces a genuine \(C\)-spectrum whose underlying spectrum is the ordinary \(K\)-Tate construction. “Strict fixed points” is interpreted as derived categorical fixed points of this genuine spectrum, not geometric fixed points and not Borel homotopy fixed points. This is the interpretation on which the results below are conditional if the source intended a different model.

05350 | AIM-ARITHMETIC_GEOMETRY-0066

A forbidden strip and a determinantal chart for ICM surfaces in P4

P / partially_solved | AIM 研讨会问题汇编

The AIM workshop list *Components of Hilbert schemes* asks in Problem 19:

The notation is \(\mathbb P^4\). A ``surface'' here is taken to be a closed, pure two-dimensional subscheme \(X\subset\mathbb P^4_k\) that is locally Cohen--Macaulay (ICM); it need not be reduced, irreducible, smooth, or nondegenerate. This interpretation is consistent with the surrounding workshop questions about Hilbert schemes and liaison. The ground field is algebraically closed. Results below involving only Hilbert polynomials and determinantal ideals work in arbitrary characteristic.

For a sufficiently general hyperplane \(H\), no associated component of \(X\) is contained in \(H\), so its equation is a nonzerodivisor on \(X\). The section \(C=X\cap H\subset H\simeq\mathbb P^3\) is therefore an ICM curve. Define \[d=\deg X=\deg C,\qquad \pi=p_a(C),\qquad \chi=\chi(\mathcal O_X). \] Taking the first difference of the Hilbert polynomial gives the convention \[P_X(n)=\chi(\mathcal O_X(n)) =\frac d2n^2+\left(\frac d2+1-\pi\right)n+\chi. \tag{1} \] Thus the first concrete geography problem is to determine which lattice triples \((d,\pi,\chi)\) occur. In the convention used by literature writing \(H(d,p,\pi)\), the surface arithmetic genus is \(p=p_a(X)=\chi-1\). For smooth integral surfaces one may further ask for \(K_X^2,c_2,q,p_g\), but smooth adjunction and the double-point formula cannot be applied without qualification to arbitrary reducible or nonreduced ICM schemes.

05351 | AIM-ALGEBRAIC_GEOMETRY-0336

A formal local model at a type-2b stable numerical quintic

P / partially_solved | AIM 研讨会问题汇编

Problem 4.2. Understand the geometry of the moduli space of stable surfaces better. Here it is probably necessary to find some nice components and study their geometry. In general, after fixing even the differentiable structure of the underlying four-manifolds, the moduli space is disconnected, its connected components are reducible, and its irreducible components may be everywhere nonreduced. In addition, the boundary may not be a divisor, and the next best substitute is not a normal crossings divisor. Also, Vakil shows that the moduli space of canonically polarized surfaces is arbitrarily singular (in a precise sense).

来源字段：https://aimath.org/WWN/birational/birational.pdf

05352 | AIM-ALGEBRAIC_GEOMETRY-0139

A four-dimensional repair for symmetric surface classes on Mbar_0,7

P / partially_solved | AIM 研讨会问题汇编

What is the effective cone of surfaces \[\operatorname{Eff}_2\!\left(\overline{\mathcal M}_{0,7}^{\mathfrak S_7}\right), \qquad \overline{\mathcal M}_{0,7}^{\mathfrak S_7} :=\overline{\mathcal M}_{0,7}/\mathfrak S_7? \]

The AIM record asks:

Throughout, \(X=\overline M_{0,7}\) over \(\mathbb C\), \(G=S_7\), \(Y=X/G\), and \(q:X\to Y\) is the finite coarse quotient. Since \(\dim X=4\), surfaces are both dimension-two and codimension-two cycles. We use real numerical classes and write \(\overline{\operatorname{Eff}}_2\) for the closure of the cone generated by effective surfaces. This is the convention called \(\operatorname{Eff}_2\) in Fulger--Lehmann.

There is an important convention warning. The invariant rational Chow/homology group upstairs, the rational Chow group of the quotient stack \([X/G]\), and the rational cycle group of the coarse quotient are related by finite-group transfer, but products of *symmetric divisors* detect only a three-dimensional quotient of the four-dimensional invariant surface space. The latter distinction is essential here.

A representation-framed stable locus and a type B2 obstruction

P / partially_solved | AIM 研讨会问题汇编

The space \(\mathscr{X}^{\mathrm{big}}\) and category \(\operatorname{MF}(\mathscr{X}^{\mathrm{big}},w)\) makes sense not just in type A. What is the analog of \((\mathscr{X}^{\mathrm{big}})^{\mathrm{stable}}\) in other types? What is the categorical analog of the map \(\operatorname{Br}_{\mathrm{ext}}\to\operatorname{Br}_{\mathrm{fin}}\).

Its exact text is:

The preceding AIM record specifies \[\mathscr X^{\mathrm{big}} =\mathfrak g\times G\times\mathfrak n\times G\times\mathfrak n. \] This agrees with the “non-reduced” two-fold space \(\mathcal X_2=\mathfrak g\times(G\times\mathfrak n)^2\) in Oblomkov--Rozansky. We work over \(\mathbb C\), take \(G\) to be a connected reductive group, \(B\subset G\) a Borel subgroup, and \(\mathfrak n=\operatorname{Lie}R_u(B)\). Fixing a nondegenerate \(G\)-invariant bilinear form \(\kappa\) on \(\mathfrak g\), the potential is \[w(X,g_1,Y_1,g_2,Y_2) =\kappa\!\left(X,\operatorname{Ad}_{g_1}Y_1-\operatorname{Ad}_{g_2}Y_2\right). \] No corruption of the source statement was found. “Stable” is interpreted through the type A construction in arXiv:1702.03569, Section 2.6.

05383 | AIM-ALGEBRAIC_GEOMETRY-0039

A restriction-truncation baseline for fixed-point Hurewicz images

P / partially_solved | AIM 研讨会问题汇编

The Hurewicz image of equivariant truncated Brown--Peterson spectra. What is the Hurewicz image of the truncated Brown--Peterson spectrum \(\mathrm{BP}^{((G))}\langle m\rangle\)?

The record comes from the 2022 AIM workshop *Equivariant techniques in stable homotopy theory*, section “Norms and the slice filtration,” Problem 4.3. The linked AIM problem-list page no longer resolves to the problem text. The wording by itself does not specify a map, so it is essential to reconstruct the intended meaning before doing mathematics.

The most strongly supported reconstruction is the **classical unit Hurewicz map into categorical fixed points**

\[h_{G,m}\colon \pi_k\mathbb S_{(2)}\longrightarrow \pi_k\bigl(\mathrm{BP}^{((G))}\langle m\rangle^G\bigr) =\pi_k^G\mathrm{BP}^{((G))}\langle m\rangle . \tag{1.1} \]

Here \(G=C_{2^n}\) is a cyclic 2-group, as in the surrounding problems and in the Hill--Hopkins--Ravenel construction, and fixed points are genuine/categorical fixed points, not homotopy fixed points. Three pieces of evidence make (1.1) substantially more than a guess:

1. the immediately preceding AIM problem asks for the image of \(J\) “in the fixed points” of the same spectrum; 2. Hill--Shi--Wang--Xu explicitly ask, after computing the slice spectral sequence, “What are the Hurewicz images of the \(C_4\)-fixed points of \(\mathrm{BP}^{((C_4))}\langle2\rangle\)?”; 3. Li--Shi--Wang--Xu use “Hurewicz image” for the unit maps \(\pi_*\mathbb S\to\pi_*BP_{\mathbb R}^{C_2}\) and related fixed-point spectra.

Because the target is 2-local, the unlocalized unit map factors uniquely through \(\mathbb S_{(2)}\), so using the 2-local sphere loses nothing.

Other plausible readings are genuinely different problems:

- the genuine \(RO(G)\)-graded unit map \(\pi_V^G\mathbb S\to\pi_V^G\mathrm{BP}^{((G))}\langle m\rangle\); - the unit into homotopy fixed points rather than categorical fixed points; - the ordinary homology Hurewicz map out of \(\pi_*\mathrm{BP}^{((G))}\langle m\rangle\).

The results below concern (1.1). In particular, the calculation for \(m=0\) below is only an integer-graded fixed-point calculation; it is not an \(RO(G)\)-graded calculation of \(H\underline{\mathbb Z}\).

05392 | AIM-ARITHMETIC_GEOMETRY-0064

A sharp uniqueness threshold and conductor-preserving flag criterion

P / partially_solved | AIM 研讨会问题汇编

The primary AIM PDF confirms that the broken expression is \(H_C\), not a product or a new invariant. It means an irreducible component of the Hilbert scheme of curves in \(\mathbb P^3\), with the Hilbert polynomial of \(C\), containing the point \([C]\).

The phrase “double curve, and triple points, pinch point, ...” is the classical description of a surface with **ordinary singularities**. The intended characteristic-zero local models are: two transverse smooth surface branches along the general point of a reduced curve \(D\), ordinary triple points analytically modeled by \(xyz=0\), and finitely many pinch points modeled by \(x^2-y^2z=0\). This interpretation agrees with the later formulation used by Hartshorne--Polini and Zhang.

Two qualifications are logically necessary.

1. If \([C]\) lies on several Hilbert components, “the component” is not defined. The conjecture must be read componentwise, or with the added hypothesis that \([C]\) is a smooth point of the Hilbert scheme (and hence lies on a unique component). 2. The degree of the double curve is not invariant in an arbitrary deformation of hypersurfaces: a ruled cubic with a double line can deform to a smooth cubic. Thus the conclusion concerns a conductor-preserving stratum, not the whole projective space of degree-\(d\) equations.

Throughout the new result below, \(k\) is algebraically closed of characteristic zero, a curve is pure of dimension one, and \(C\) is smooth. The elementary degree estimates themselves are valid over any algebraically closed field.

05395 | AIM-ALGEBRAIC_GEOMETRY-0007

A Sullivan-Milnor-Moore obstruction screen for Weinstein cocore algebras

P / partially_solved | AIM 研讨会问题汇编

Can the “looking glass” parallel/analogy between rational homotopy theory (= symplectic geometry of cotangent bundles) and local ring theory be generalized/further exploited to other symplectic manifolds (e.g. Weinstein manifolds)?

A) one can attach handles to Weinstein manifolds; there exists a natural “categorical compactification” of Fukaya categories via a stop or Lefschetz fibration.

B) Can rational homotopy theory, e.g. Sullivan minimal models, be used to construct resolutions?

This is Problem 3.1, “Symplectic geometry,” from the AIM workshop list *Syzygies and mirror symmetry*.

The record gives the motivating formulas \[C_*(\Omega_qM) =\operatorname{Ext}_{C^\bullet(M)}(k,k)=A, \qquad C_*(\Omega_qM)\simeq \operatorname{End}_{\operatorname{Fuk}(T^*M)}(T_q^*M,T_q^*M), \] with \(M\) simply connected.

The original AIM URL was attempted on 22 July 2026 but did not return usable content through the available web reader. No missing mathematical symbol had to be reconstructed. Two notational corrections are essential:

1. at chain level, \(\operatorname{Ext}\) must be replaced by the derived endomorphism dga/\(A_\infty\)-algebra \(\mathbb R\operatorname{Hom}\); \(\operatorname{Ext}\) ordinarily denotes its cohomology; 2. the Floer-theoretic statement is an \(A_\infty\) quasi-isomorphism, with grading, orientation/background-class, and coefficient conventions, not an equality of chain complexes.

With cohomological grading \(C_{-*}^i=C_{-i}\), the precise cotangent pattern used below is \[CW^*(T_q^*M,T_q^*M;k)\simeq_{A_\infty} C_{-*}(\Omega_qM;k) \simeq_{A_\infty} \mathbb R\operatorname{Hom}_{C^*(M;k)}(k,k). \tag{1} \] Abouzaid proves the first quasi-isomorphism for a closed smooth base (with the appropriate background class, or a corresponding local-system twist). Simple connectedness is not needed for that Floer/loop comparison. It is imposed here for the clean Eilenberg-Moore/Koszul-duality statement and for Sullivan rational homotopy theory.

A two-source specialization-defect formula and the post-2025 status of plurigenera

P / partially_solved | AIM 研讨会问题汇编

Invariance of plurigenera. What is the status of invariance of plurigenera?

It is known that \(h^0(mK_X)\) need not be constant in flat families if \(m=1\). For \(m\geq 2\) it remains a possibility.

Recovered present-day answer. The optimistic \(m\geq2\) statement is false in general. It is false logarithmically already for smooth families of surface pairs in every residue characteristic, by Brivio's published 2023 examples. A June 2025 revision of a separate Brivio preprint states that it is also false without boundary for smooth projective families of threefolds with semiample canonical divisor and residue characteristic \(p>2\). Important positive regimes remain, particularly in characteristic zero, for many surface families, and for stable families satisfying base-change and vanishing conditions.

Does $\pi_*[\overline{M}_g(X,\beta)]^{\operatorname{vir}}\in H^*(\overline{M}_g)$ lie in the tautological ring in cohomology?

Q2. When does $\pi_*[\overline{M}_g(X,\beta)]^{\operatorname{vir}}\in A^*(\overline{M}_g)$ lie in the tautological ring in Chow?

I would guess the answer to $**Q1**$ is yes. If X is a curve, an affirmative answer to $**Q1**$ follows from the results of [fabp]. We know $\pi_*[\overline{M}_g(X,\beta)]^{\operatorname{vir}}$ does not always lie in the tautological ring in Chow --- counterexamples can be found when X is a curve. A wild speculation, motivated by the Bloch-Beilinson conjecture, is that the answer to **Q2** is yes when X is defined over over $\overline{\mathbb{Q}}$.

Donaldson--Thomas invariants are defined only in dimension 3 because a virtual fundamental class for the moduli space of sheaves is required. Deformations are given by $\operatorname{Ext}^1(E,E)$, obstructions by $\operatorname{Ext}^2(E,E)$, and to define the virtual fundamental class we need (roughly) the vanishing $$\operatorname{Ext}^i(E,E)=0 \ \ \text{for}\ \ i>2 \ .$$ On 3-folds, the vanishing can often be obtained using Serre duality and stability. However, there are parallel examples of enumerative computations in higher dimensions in Gromov-Witten theory [klp,pz]. Moreover, many aspects of Joyce's counting theory are valid in higher dimensions [J].

Define Donaldson--Thomas invariants in dimensions >3.

An explicit smooth locus for the coprime-degree cubic family

P / partially_solved | AIM 研讨会问题汇编

Does there exist an irrational unirational variety with unirational parametrizations of coprime degrees?

Recovered answer. Yes. In August 2025, Song Yang, Xun Yu, and Zigang Zhu produced a two-dimensional family of smooth cubic threefolds with parametrizations of degrees 2 and 3. Every smooth complex cubic threefold is irrational by Clemens--Griffiths. Thus their examples answer the AIM question affirmatively.

05467 | AIM-ALGEBRAIC_GEOMETRY-0059

An oriented preservation calculus for categorical representability in codimension two

P / partially_solved | AIM 研讨会问题汇编

Which birational transformations preserve the following property?

\[D(X)=\langle \mathscr A_1,\ldots,\mathscr A_m\rangle \] has a semiorthogonal decomposition with \(\mathscr A_i\hookrightarrow D(Y_i)\) such that \({\rm dim}\,Y_i\leq {\rm dim}\,X-2\). For future reference, we call this property (*).

Its problem text is:

The standard precise reading is the following. For a smooth projective variety \(X\), \(D(X)\) means \(D^b_{\mathrm{coh}}(X)\). Each \(\mathscr A_i\) is an admissible component, and \(\mathscr A_i\hookrightarrow D(Y_i)\) means that \(\mathscr A_i\) is equivalent to an admissible subcategory of \(D^b_{\mathrm{coh}}(Y_i)\), where \(Y_i\) is smooth and projective. This is categorical representability in dimension at most \(\dim X-2\), or in codimension at least two. Without admissibility the stated property is too weak for the usual formalism and does not agree with the cited definition.

Throughout the mathematical result below, the ground field is \(\mathbb C\), varieties are smooth and projective, and \(n=\dim X\geq2\). The categorical preservation statements themselves work over any field for which the invoked semiorthogonal decompositions hold; \(\mathbb C\) is used for the Hochschild--Hodge interpretation and avoids field qualifications.

Boundedness after fixing the birational model

S / solved | AIM 研讨会问题汇编

Problem 1.4 (Alexeev). Are the following classes of varieties bounded? Here bounded means that all members of the class can be put into a family over a base of finite type.

1. Semi-log canonical varieties of general type with fixed \(K^n\). 2. \(\epsilon\)-log terminal Fano varieties.

The words “1.3. Positive characteristic issues” begin the following subsection and are not part of Problem 1.4.

Two parameters have to be regarded as fixed: the dimension \(n\), and in (2) the real number \(\epsilon>0\). Without fixed dimension even the smooth projective spaces would make (2) unbounded. The source does not explicitly state a ground field in this sentence. Its placement immediately before the positive-characteristic subsection, and the later theorems that resolved it, support the usual characteristic-zero reading.

Brauer lifts and Beauville--Mukai torsors

P / partially_solved | AIM 研讨会问题汇编

Let X be a K3 surface of degree $2d$. Consider the Hilbert scheme $\mathscr{H}$ of length $d+1$ zero-dimensional subschemes of X. $\mathrm{Br}(X)=\mathrm{Br}(\mathscr{H})$. There is a map $\mathscr{H}\to\mathbb P^{d+1}$ with generic fiber an abelian variety. Does every $\alpha\in\mathrm{Br}(X)$ be correspond to a torsor for the relative Jacobian of this vibration in such a way that the order of the torsor associated to α times the order of α is the order of the torsor $\mathscr H$? In this question we are using the same correspondence between principal homogeneous spaces and Brauer classes as in Bianca's talk.

If we consider the moduli space of α-twisted sheaves on X of dimension 0 and length $d+1$, does this realize the torsors of the previous part of this question?

Characteristic-zero specialization and an odd-index theorem for cubic fourfolds

P / partially_solved | AIM 研讨会问题汇编

“If the general member of a family of smooth cubic is rational, is the special fiber also rational?”

The statement leaves four mathematically important choices unspecified:

1. “cubic” could mean a cubic curve, surface, threefold, fourfold, or an arbitrary cubic hypersurface; 2. “general” could mean the generic fiber, the geometric generic fiber, every point of a dense open set, a very general point, or merely a dense set of points; 3. rationality could mean rationality over the stated residue field or geometric rationality after algebraic closure; 4. the base could be a curve over a field or a mixed-characteristic trait.

The immediately preceding AIM Problem 3.07 explicitly concerns reductions of a cubic fourfold, and the workshop is about positive characteristic. It is therefore plausible that cubic fourfolds in positive or mixed characteristic were intended, but the source does not verify this. This report treats the two most useful precise readings:

- a smooth proper family over a characteristic-zero curve whose (geometric) generic fiber is rational; - a DVR family of smooth cubic fourfolds, possibly in positive or mixed characteristic, for which rationality is witnessed by projection from a plane and an odd-degree multisection.

Dimension checks confirm why the fourfold reading is natural. A smooth plane cubic is geometrically a genus-one curve and is not rational. A smooth cubic surface over an algebraically closed field is rational, so the geometric question is automatic in dimension two. Over \(\mathbb C\), every smooth cubic threefold is irrational. Cubic fourfold rationality is the first classical case in this sequence for which the general rationality problem remains genuinely subtle.

Characteristic-zero status and a fixed-volume bridge for stable n-folds

S / solved | AIM 研讨会问题汇编

Problem 1.3 (Higher dimensions). In [Kar00], Karu proves that the semistable minimal model program in dimension \(n+1\) can be used (together with the weak semistable reduction of Abramovich and Karu) to construct the moduli space of smoothable stable \(n\)-folds. See the previous problem for problems with this approach. This is what needs to be done to avoid the MMP:

1. Prove boundedness of slc \(n\)-folds with fixed \(K^n\) (see Alexeev's problems below). The semistable MMP is not strong enough to do this for non-smoothable \(n\)-folds anyway. 2. Prove that small \(\mathbb Q\)-Gorenstein deformations of slc singularities are slc. It is true that small \(\mathbb Q\)-Gorenstein deformations of slt singularities are slt. Again, the MMP in one dimension higher would verify this. 3. Verify the valuative criterion for properness for non-smoothable \(n\)-folds. The MMP gives the valuative criterion in the smoothable case.

Cohomological Dimension of Meromorphic Function Fields

P / partially_solved | Oberwolfach 报告问题汇编

Let S be a connected normal Stein space of complex dimension n. Is the cohomological dimension of its field of meromorphic functions equal to n, that is, does $\operatorname{cd}(\mathcal M(S))=n$ hold? The question remains open in dimensions $n\geq 3$.

Cubic maximal rank after the classical theorem

S / solved | AIM 研讨会问题汇编

Problem 8

(Suggested by David Jensen) The Maximal Rank Conjecture predicts the Hilbert fuction of a general curve (for fixed g, r, d such that ρ(g, r, d) ≥ 0 and r ≥ 3). The Hilbert function measures the rank of the map Sym m H0(X, L) → H0(X, L⊗m). The Maximal Rank Conjecture predicts that this has maximal rank for general X and L.Concretely, this means that it is either injective or surjective. We proposed a combinatorial approach via the notion of tropical independence. How-ever, we can only solve the combinatorial problem for h(2) (the case of quadrics). The next step would be h(3), i.e. cubics.

Recovered Problem 8. Determine \(h_V(3)\) for a general Brill-Noether curve/linear series with \(r\geq3\), and, in the direction proposed at the workshop, prove the predicted maximal-rank statement by a tropical-independence certificate.

Duality, epipoles, and a Segre cubic from four correspondences

P / partially_solved | AIM 研讨会问题汇编

For any of the standard varieties considered it might be possible to study the projective dual. What can we learn from studying these objects?

Source: <http://aimpl.org/algvision/2/>. The live page was checked on 2026-07-23; it has exactly this wording and no status, introduction, or remarks.

“The standard varieties” is not enumerated on that page. Nearby records in the preceding “Reconstruction” section explicitly mention the essential variety, the trifocal tensor variety, the fundamental matrix, and the Hurwitz form of the essential variety. I therefore interpret the prompt as a program for such camera and tensor varieties, not as a request about every projective variety.

To obtain a rigorous result rather than a broad catalogue, this report focuses on the uncalibrated two-view **fundamental-matrix variety** \[X=\{[F]\in\mathbb P(\operatorname{Mat}_{3\times3}(\mathbb C)): \det F=0\}\subset\mathbb P^8. \] Its projective dual can be determined completely. More importantly, its dual points are exactly the rank-one coefficient matrices of point-correspondence constraints. This leads to an explicit theorem: four point correspondences that form projective frames cut \(X\) in a Segre cubic threefold with ten ordinary double points, split canonically into six rank-one inherited nodes and four rank-two dual-contact nodes.

This is a developed special case and not a solution of the entire open-ended program for essential, trifocal, quadrifocal, and multiview varieties.

05713 | AIM-ALGEBRAIC_GEOMETRY-0233

Euler parity and complete cubic cancellation profiles for plane Welschinger counts

P / partially_solved | AIM 研讨会问题汇编

Recovered statement. Fix a generic conjugation-invariant configuration \(\boldsymbol p\subset \mathbb P^2\) consisting of \(d_1\) real points and \(d_2\) pairs of complex-conjugate points, where \[d_1+2d_2=3d-1. \] Let \(\mathcal R_d(\boldsymbol p)\) be the finite set of irreducible real rational degree-\(d\) plane curves through \(\boldsymbol p\). For generic constraints these curves are nodal. If \(s(C)\) is the number of solitary (elliptic) real nodes of \(C\), define \[W_2(d,d_2)=\sum_{C\in\mathcal R_d(\boldsymbol p)}(-1)^{s(C)}. \] Welschinger's theorem makes this signed count independent of the generic configuration. The question in Remark 9.1 is to understand its sign as a function of \(d_1,d_2\); the source suggests a sign-reversing injection as a possible explanation.

Extreme effective cones and stable Schubert bounds for Plucker hypersurfaces

P / partially_solved | AIM 研讨会问题汇编

Recovered question. If \(X\subset Gr(m,n)\) is a very general hypersurface, what is \(\operatorname{Eff}_k(X)\)?

Its final sentence is

There is no object \(K\) in the record. The preceding clause introduces \(X\), and the question asks for cycles on the hypersurface. Thus the only coherent recovery is

The replacement \(K\rightsquigarrow X\) is a correction of an apparent typo, not a change to the mathematical question. The source also does not specify whether \(Gr(m,n)\) parametrizes projective \(m\)-planes or \(m\)-dimensional vector subspaces. In this report \[G=\operatorname{Gr}(r,V)=\operatorname{Gr}(r,n) \] parametrizes \(r\)-dimensional vector subspaces of an \(n\)-dimensional complex vector space, with \(1\leq r\leq n-1\). Thus \[g:=\dim G=r(n-r). \] Write \(H=c_1(\mathcal O_G(1))\) for the Plücker hyperplane class. A degree-\(d\) hypersurface means a divisor \[X\in |dH|,\qquad d\geq 1. \] We assume that \(X\) is smooth and put \(m=\dim X=g-1\). The conclusions below hold for every smooth member, and hence for a very general member when the smooth locus of the linear system is nonempty.

The word “effective cone” is interpreted as the **closed pseudoeffective cone** \[\overline{\operatorname{Eff}}_k(X)\subset N_k(X)_{\mathbb R}, \] the closure of the cone generated by effective \(k\)-dimensional algebraic cycles. This is the convention used in the modern higher-cycle literature. For all cones computed exactly below, taking the closure makes no difference.

05774 | AIM-ALGEBRAIC_GEOMETRY-0202

Finite algebraic certificates for recognition by invariant signatures

P / partially_solved | AIM 研讨会问题汇编

How can we use these signatures for object recognition?

The archived section introduction says: "From a differential geometry perspective we can assign invariants to a smooth curve or surface. This allows us to assign a signature curve to each curve." The neighboring questions ask about completeness, degree, automorphism groups, realizability, and moduli of signature curves. The workshop report identifies the relevant day as "Shapes, silhouettes, and contours," with talks by Matthew Trager, Peter Olver, and Irina Kogan. Thus "these signatures" means invariant signature curves of geometric boundaries, especially differential signatures, with algebraic signatures as a central workshop specialization.

For an oriented regular planar curve under the proper Euclidean group \(SE(2)\), the classical smooth signature is \[s\longmapsto \bigl(\kappa(s),\kappa_s(s)\bigr), \] where \(s\) is Euclidean arc length. Analogous signatures use equi-affine or projective differential invariants. For algebraic curves it is advantageous to use a *rational classifying pair*. For example, Kogan--Ruddy--Vinzant use \((\kappa^2,\kappa_s)\) for the complexified \(SE(2)\)-action. They also give rational pairs for \(SA(2)\), \(A(2)\), and \(PGL(3)\).

"Recognition" is interpreted mathematically as deciding whether two boundary curves lie in the same orbit of a specified transformation group \(G\). This is not the same as assigning a semantic label such as "car" or "chair." A semantic classifier may use invariant signatures as features, but its statistical generalization is a separate question.

The original live `aimpl.org` URL now redirects to a missing page.

05775 | AIM-ALGEBRAIC_GEOMETRY-0141

Finite complete-intersection mobility bounds for the line class in projective three-space

P / partially_solved | AIM 研讨会问题汇编

Let \(X\) be an \(n\)-dimensional variety. Given an effective integral \(k\)-cycle \(\alpha\in N_k(X)_{\mathbb Z}\), the mobility count \(mc(\alpha)\) is the maximum number of general points that can be imposed on an effective cycle of class \(\alpha\). It then displays formulas for mobility and an Iitaka-type exponent and asks, after introducing the line class \([\ell]\in N_1(\mathbb P^3)_{\mathbb Z}\), “What is \(\operatorname{mob}([\alpha])\)?”

Over \(\mathbb C\), let \(\ell\) be the numerical class of a line in \(\mathbb P^3\). Determine \[\operatorname{mob}(\ell) =\limsup_{m\to\infty}\frac{6\,mc(m\ell)}{m^{3/2}}. \]

1. The displayed mobility formula in the record has no limiting operation. The standard definition in [Leh16, Definition 1.1] is \[\operatorname{mob}(\alpha) := \limsup_{m\to\infty} \frac{mc(m\alpha)} {m^{\,n/(n-k)}/n!} = \limsup_{m\to\infty} \frac{n!\,mc(m\alpha)}{m^{\,n/(n-k)}}. \tag{1.1} \] The denominator \(m^{n/(n-k)}/n!\) is the standard normalization. 2. The last \([\alpha]\) is reconstructed as \([\ell]\). This is confirmed by the fuller AIM problem-list transcript, which asks for the mobility when \(\alpha\) is the line class on \(\mathbb P^3\). 3. The AIM record calls the unrescaled growth exponent \[K_{\mathrm{src}}(\alpha) := \sup\left\{r\geq0: \limsup_{m\to\infty}\frac{mc(m\alpha)}{m^r}>0 \right\}. \tag{1.2} \] Lehmann's later convention [Leh19] multiplies this exponent by the codimension: \[\kappa(\alpha)=(n-k)K_{\mathrm{src}}(\alpha). \tag{1.3} \] Both conventions will be reported explicitly.

Thus the recovered problem is:

Finite-jet detection of log canonical thresholds with quantitative bounds

S / solved | AIM 研讨会问题汇编

3. (Mustaţă) We have the ACC conjecture for log canonical thresholds (Conjecture 2.5 of [6], see also [3]). When we consider only smooth varieties, the conjecture is equivalent to the following question:

Fix \(n\). \(\forall c\in\mathbb R\), does there exist \(k=k(c)\) such that \[\{f\in\mathbb C[[x_1,\ldots,x_n]]\mid \operatorname{lct}(f)\geq c\} \] depends on \(k\)-th truncations of \(f\)?

A weaker question is: Does there exist \(k=k(f)\) such that \(\operatorname{lct}(f+g)\geq\operatorname{lct}(f)\) for all \(g\) with \(\operatorname{ord}(g)\geq k\)?

Gauss-inseparability strata and a Frobenius plane-curve family

P / partially_solved | AIM 研讨会问题汇编

Fix \(d,g,r,e>0\) in characteristic \(p\). Let \[\operatorname{Hilb}^{\mathrm{sm}}_{d,g}(\mathbb P^r) \subset \operatorname{Hilb}_{d,g}(\mathbb P^r) \] be the open subscheme parametrizing smooth curves. For \([C]\in\operatorname{Hilb}^{\mathrm{sm}}_{d,g}(\mathbb P^r)\), let \[\gamma_C:C\longrightarrow \operatorname{Gr}(1,r) \] be the Gauss map sending a point to its embedded tangent line, and define \[Z_e=\left\{[C]\in\operatorname{Hilb}^{\mathrm{sm}}_{d,g}(\mathbb P^r): \deg_{\mathrm{ins}}(\gamma_C)=p^e\right\}. \] Then \[\bigcup_{e\ge 0}Z_e=\operatorname{Hilb}^{\mathrm{sm}}_{d,g}(\mathbb P^r). \] The questions are: what can be said about \(Z_e\); can this stratification construct exotic components existing only in characteristic \(p\); and how does \[\operatorname{Gal}(\overline{\mathbb F}_p/\mathbb F_p) \] act? The source also suggests stratification by the topological type of the ramification divisor.

The phrase “smooth curves” is interpreted below as smooth, geometrically integral, nondegenerate curves. This is the standard setting in which the Gauss map has one function-field extension and hence one inseparable degree. For a disconnected smooth curve the definition must instead be made componentwise.

Question (Anastasia Stavrova). When \(G\) is a linear reduced/algebraic group, in a large number of cases, it is known on a case-by-case basis that \(\Pi^{\mathbb A^1}_0(G)\) is abelian. Is this always true? Can this be obtained in a uniform way when it is true?

Remark (Madhav Nori). This is not always true e.g. \(G=SU(2,\mathbb R)\). In fact, the same reasoning should show that \(\Pi^{\mathbb A^1}_0(G)\) is not abelian for any anisotropic group \(G\) over \(\mathbb R\).

05847 | AIM-ALGEBRAIC_GEOMETRY-0042

Geometric-fixed-point sparsity in the orbit--Koszul Bockstein filtration

P / partially_solved | AIM 研讨会问题汇编

The $(G\cdot\overline v_n)$-Bockstein spectral sequence for $\mathrm{BP}^{((G))}\langle n\rangle$. $\mathrm{BP}^{((G))}\langle n-1\rangle$ is the quotient of $\mathrm{BP}^{((G))}\langle n\rangle$ by $(G\cdot\overline v_n)$. Can one understand the $(G\cdot\overline v_n)$-Bockstein spectral sequence for this quotient map?

The preceding problem in the same source section explicitly works with C_{2^r}. Accordingly, and consistently with the primary literature, I recover $G=C_{2^r}$, with $r\geq 1$. I use m for the truncation index so that it is not confused with the exponent r in the group order. Put

$$ q=[G:C_2]=2^{r-1},\qquad R_m=\mathrm{BP}^{((G))}\langle m\rangle. $$

$$ \mathrm{BP}^{((G))}=N_{C_2}^G\mathrm{BP}_{\mathbb R} $$

and one can choose classes

$$ \bar t_i^G\in \pi_{(2^i-1)\rho_2}^{C_2}\mathrm{BP}^{((G))} $$

whose restrictions t_i^G give polynomial generators. Modern papers often write $\bar t_i^G$, while the AIM record writes $\bar v_i$. The precise construction below only requires a chosen generator of the corresponding permutation summand; it does not require identifying every possible choice of $\bar v_i$ with $\bar t_i^G$.

If γ generates G, then

$$ G\cdot\bar t_i^G= \{\bar t_i^G,\gamma\bar t_i^G,\ldots,\gamma^{q-1}\bar t_i^G\}. $$

This notation denotes a **list of q orbit generators**, not their product. The signed relation is $\gamma^q\bar t_i^G=-\bar t_i^G$, so it does not add another polynomial generator. By contrast, $N_{C_2}^G(\bar t_i^G)$ denotes the multiplicative norm, whose underlying class is the product of the orbit elements up to the standard norm conventions.

The consistent truncation convention is

$$ R_m=\mathrm{BP}^{((G))}/ \bigl(G\cdot\bar t_{m+1}^G,G\cdot\bar t_{m+2}^G,\ldots\bigr), \qquad R_{m-1}\simeq R_m/(G\cdot\bar t_m^G). \tag{1.1} $$

Carrick--Hill, arXiv:2507.07051v1, gives (1.1) in its introductory definition and again states the quotient relation after Definition 4.3. The displayed formula inside Definition 4.3 itself starts the colimit at $\bar t_m^G$; this is an apparent off-by-one typo, since it contradicts both the earlier definition and the immediately following quotient relation. I use the internally consistent convention (1.1).

Hirzebruch's 1954 Problem List - Problem 1

O / open | AMR 问题清单汇编

At the beginning of June,1953, Hirzebruch proved what he then called the ``index theorem'': $$ \tau (M) = \langle L(p_1,\ldots,p_k),[M]\rangle \ , $$ where $M$ is any closed smooth oriented manifold, $\tau (M)$ is its index or signature, and $L(p_1,\ldots,p_k)$ is the $L$-polynomial in the Pontrygain classes of $M$. Later on the term ``index'' became monopolized by the Fredholm index appearing in the Atiyah--Singer index theorem, and so $\tau (M)$ is now usually called the signature, and the ``index theorem'' has become the Hirzebruch signature theorem.

Give an elementary proof of the index theorem and explain the geometrical meaning of the functional equation valid for τ.

\mathrm{a)} Let L be a nontrivial nef line bundle on X with $q(L)=0$. There exists a Lagrangian fibration $f:X\rightarrow \mathbb{P}^r$ such that $L=f^*\mathcal{O}_{\mathbb{P}^r}(k)$ for some $k\geq 1$. \mathrm{b)} There exists a hyperk\"ahler manifold X' bimeromorphic to X and a Lagrangian fibration $X'\rightarrow \mathbb{P}^r$ if and only if X admits a line bundle $L\neq \mathcal{O}_S$ with $q(L)=0$.

背景链接：https://arxiv.org/abs/1002.4321

05920 | AMR-118-0001

Holomorphic Symplectic Geometry - Question 1

O / open | AMR 问题清单汇编

In the two last examples it would seem simpler to start with a moduli space $\mathcal{M}$ for which the natural compactification $\overline{\mathcal{M}}$ is smooth; in that case $\overline{\mathcal{M}}$ is a hyperk\"ahler manifold [M], but it turns out that it is a deformation of $S^{[r]}$ or $K_r(T)$ (G\"ottsche-Huybrechts, O'Grady, Yoshioka ...). On the other hand, when $\overline{\mathcal{M}}$ is singular, it admits a hyperk\"ahler desingularization only in the two cases considered by O'Grady [KLS]. Thus it seems that a new idea is required to answer our first problem:

Find new examples of hyperk\"ahler manifolds.

Let X, X' be two hyperk\"ahler manifolds of the same dimension. If there is a Hodge isometry $\lambda :H^2(X,\mathbb{Z})\vbox{\hbox to .8cm{\hfill{$\scriptstyle\sim$}\hfill} \nointerlineskip\hbox to .8cm{{\hfill$\longrightarrow $\hfill}} } H^2(X',\mathbb{Z})$, what can we say of X and X'? Can we conclude that X and X' are isomorphic by imposing that $\lambda $ preserves some extra structure?

背景链接：https://arxiv.org/abs/1002.4321

05922 | AMR-118-0003

Holomorphic Symplectic Geometry - Question 3

O / open | AMR 问题清单汇编

Thus the subalgebra $\mathcal{H}$ is completely determined by the form q and the dimension of X. In contrast, not much is known about the $\mathcal{H}$-module $\mathcal{H}^\perp$. Note that it is nonzero for the examples $a)$ and $b)$ of 1.2, with the exception of $S^{[2]}$ for a K3 surface S. We do not know much about the quadratic form q either. For the two infinite series of (1.2) we have lattice isomorphisms [B1] \[H^2(S^{[r]},\mathbb{Z})=H^2(S,\mathbb{Z}) \buildrel {\scriptscriptstyle\perp}\over {\oplus} \langle 2-2r\rangle\qquad H^2(K_r(T),\mathbb{Z})=H^2(T,\mathbb{Z}) \buildrel {\scriptscriptstyle\perp}\over {\oplus} \langle -2-2r\rangle\ ; \] The lattices of O'Grady's two examples are computed in [R]; they are also even.

Is the quadratic form q always even? More generally, what are the possibilities for q? What are the possibilities for the Fujiki index f_X (see 1.3)?

Iterated differential signatures as a quotient tower

P / partially_solved | AIM 研讨会问题汇编

AIM Problem 3.4 (Invariants). “What can we say about the signature of the signature of a curve?”

The workshop schedule places talks by Peter Olver and Irina Kogan on the same day, and the participant compilation records Olver's interest in differential-invariant signatures; this supports the reconstructed setting without identifying an author for the problem.

The following reconstruction is therefore used.

Let \(G\subset \operatorname{PGL}_3(\mathbb C)\) be a positive-dimensional closed algebraic group acting rationally on the affine plane. Let \[I=(K_1,K_2) \] be a rational classifying pair of differential invariants for the prolonged \(G\)-action. For a suitable irreducible plane curve \(X\), restriction gives the rational signature map \[\sigma_X=(K_1|_X,K_2|_X):X\dashrightarrow \mathbb A^2, \] and the Zariski closure \[\mathcal S_I(X)=\overline{\sigma_X(X)} \] is its signature curve. The question asks what happens when the signature construction is applied again to \(\mathcal S_I(X)\).

Linear-center effective cones and the vertical exceptional face

P / partially_solved | AIM 研讨会问题汇编

Let \(Z\subset \mathbb P^n\) be a smooth subvariety with \(1\leq \dim Z\leq n-2\). What is the effective cone of \(k\)-cycles \(\operatorname{Eff}_k(X)\)?

Its mathematical prompt is:

The immediately preceding sentences ask for the relationship between the effective cones of a variety and “its blowup,” and then discuss a positive-dimensional blowup center in \(\mathbb P^n\). Thus throughout this report the reconstructed meaning is

\[X=\operatorname{Bl}_Z(\mathbb P^n),\qquad \pi:X\longrightarrow \mathbb P^n. \]

This reconstruction is necessary and is not silently attributed to the source. The source remark proposes as first examples a small union of lines and low-degree, low-codimension complete intersections. A union of pairwise disjoint lines is a smooth disconnected center; a union of intersecting lines is singular and lies outside the displayed smooth-center hypothesis.

Unless otherwise stated, varieties are over an algebraically closed field. The comparison with the complex literature is made over \(\mathbb C\). The linear-center calculation below is characteristic-independent.

Matroid classification and a sharp four-factor Cohen-Macaulay obstruction

P / partially_solved | AIM 研讨会问题汇编

Let X be a variety in a generalized flag manifold G/P, with Schubert varieties X_w ($w \in W/W_P$). Say that X is *multiplicity-free* if in cohomology $[X] = \sum_{s \in S} [X_s]$ for a subset $S \subset W/W_P$. By a theorem of Brion, if X is reduced, irreducible, and multiplicity-free, then X admits a flat degeneration to the reduced union $\bigcup_{s \in S} X_s$, and this union is Cohen--Macaulay.

Problem 2.2 (Knutson). Classify subsets $S \subset W/W_P$ that deform to irreducibles (i.e., such that $\bigcup_{s \in S} X_s$ is the special fiber of a flat degeneration of an irreducible subvariety $X \subset G/P$). For example, is it sufficient that $\bigcup_{s \in S} X_s$ be Cohen--Macaulay? The first case to try is $G/P \cong (\mathbb{P}^1)^n$.

Monomial signatures distinguish components through affine length eight

P / partially_solved | AIM 研讨会问题汇编

The AIM record (Problem 16 in *Components of Hilbert schemes*) asks:

For an irreducible component \(C\), define its full monomial signature by \[\operatorname{Mon}(C)=\{I:[I]\in C\text{ and }I\text{ is monomial}\}. \] The question is whether \(C\mapsto\operatorname{Mon}(C)\) is injective. It is important that the question concerns equality of the entire sets, not whether two components share one monomial ideal.

The source remarks that Richard Liebling might have given a counterexample for a Hilbert scheme of curves in his 1996 thesis. The thesis and later citations were identified, but accessible sources did not verify this precise assertion. A statement about generic initial ideals would not by itself establish equality of the full monomial signatures.

Movable versus divisorial canonicity in degrees four and five

P / partially_solved | AIM 研讨会问题汇编

The record comes from Problem 17 (Cheltsov) in the AIM workshop list *Numerical invariants of singularities and higher-dimensional algebraic varieties*.

Let \(X\) be a smooth Fano variety with \(\operatorname{Pic}X=\mathbb Z\). Is birational superrigidity equivalent to

\[\tag{1} \text{for every movable }\mathcal M\subset |-mK_X|,\qquad \left(X,\frac1m\mathcal M\right)\text{ is canonical} \]

for every \(m>0\)? Here “movable” is the phrase “with no fixed components” in the source. A second condition is

\[\tag{2} \text{for every }D\in |-mK_X|,\qquad \left(X,\frac1mD\right)\text{ is canonical (or plt)} \]

for every \(m>0\). The note then says that if (1) and (2) hold, the only Mori fibre structures on \(X\times\mathbb P^1\) are the two projections, and adds: “More precisely, every birational map from \(X\times\mathbb P^1\) to another Mori fiber space is an isomorphism.” Finally it cites Pukhlikov for (1) and (2) on a sufficiently general hypersurface

\[X_N\subset\mathbb P^N,\qquad \deg X_N=N,\qquad N\geq 6, \]

and asks what happens for \(N=4\) and \(N=5\). Thus \(X_4\) is a quartic threefold and \(X_5\) is a quintic fourfold.

They are treated separately below. All varieties are over \(\mathbb C\).

06087 | AIM-ARITHMETIC_GEOMETRY-0027

No essential transcendental Brauer-Manin obstruction on abelian torsors

S / solved | AIM 研讨会问题汇编

Does any Abelian variety have a transcendental Brauer class which obstructs the existence of rational points?

A theorem of Manin says that if an Abelian variety has a transcendental Brauer class, and $\mathrm{Sha}(A)$ is finite, E a torsor for A, and $E(\mathbb{A})^{\mathrm{Br}_{\mathrm{alg}}} \neq \emptyset$, then $E(K) \neq \emptyset$. Can we show that the existence of a transcendental obstruction implies the existence of algebraic obstructions which rule out the same adelic points as coming from global points?

The stored source URL is http://aimpl.org/brauermoduli/2/; the surviving official workshop page is https://aimath.org/pastworkshops/brauermoduli.html.

The text needs two repairs before it becomes a coherent mathematical question.

1. An abelian variety A/k, as opposed to a torsor under it, has its identity $0\in A(k)$. Therefore no Brauer class can obstruct the *existence* of a rational point on A. The diagonal adelic identity is orthogonal to every Brauer class. 2. The clause “if an Abelian variety has a transcendental Brauer class” plays no role in the Manin statement. The intended non-pointed object is a torsor X (called E in the record) under an abelian variety A over a number field k.

The intended problem has three logically different readings.

- **Essential transcendental obstruction:** can \[X(\mathbb A_k)^{\operatorname{Br}_1X}\ne\varnothing \quad\text{but}\quad X(\mathbb A_k)^{\operatorname{Br}X}=\varnothing? \] - **Obstruction-level replacement:** if one or more possibly transcendental classes make a Brauer--Manin set empty, is there an algebraic class (or algebraic subgroup) that also makes it empty? - **Pointwise/classwise simulation:** can the Brauer--Manin evaluation function or the zero set of each individual transcendental class always be reproduced by algebraic classes?

The first two readings are solved affirmatively in the desired direction: essential transcendental obstructions do not occur, and an emptiness obstruction is captured by a single locally constant algebraic class. The third, much stronger reading is not what the known theorem says.

All results below concern number fields. For a genuine Brauer--Manin obstruction to the Hasse principle we assume $X(\mathbb A_k)\ne\varnothing$.

Nonstabilization of pluricanonical GIT and a finite-wall diagnostic

S / solved | AIM 研讨会问题汇编

Problem 3.1 (from Kollár's lecture). Fix a class of (pluri)canonically embedded manifolds in \(\mathbf P^n\). There is a notion of GIT semistability for Hilbert points in the closure of the Hilbert points of the class of manifolds considered. Now embed the family in another \(\mathbf P^m\) using a higher power of \(K_X\) and consider the GIT semistability conditions in that projective space. Is there an integer \(N\) such that the class of GIT semistable surfaces stabilizes for embeddings by \(M K_X\) for \(M>N\)? This problem is fundamental, and the answer for curves is that \(N=5\).

06115 | AIM-ALGEBRAIC_GEOMETRY-0029

Odd-prime solution and completion-transfer reduction

P / partially_solved | AIM 研讨会问题汇编

Fix a prime \(p\). Let \[j_p=\tau_{\geq 0}L_{K(1)}\mathbb S. \] Is there an equivalence \[\operatorname{TP}(\mathbb Z_p)\simeq (j_p^{\mathrm{triv}})^{tS^1}, \] where the circle acts trivially on \(j_p\)?

The record adds that this would follow, for example, from \(\operatorname{TR}(\mathbb Z_p)\simeq j_p\). There is no visible corruption in the record. The citation `MR1317575` is Hesselholt--Madsen, *The \(S^1\)-Tate spectrum for \(J\)*.

There is one convention that must be made explicit. In this fixed-prime context, the natural modern reading is continuous (or \(p\)-complete) periodic topological cyclic homology \[\operatorname{TP}(R;\mathbb Z_p) :=\bigl(\operatorname{THH}(R)^{tS^1}\bigr)^\wedge_p. \] The right side is built from the \(p\)-complete image-of-\(J\) spectrum. The theorem below proves the conjecture under this reading. If the displayed source statement is read as an assertion about *uncompleted* \(\operatorname{TP}(H\mathbb Z_p)\), only its \(p\)-completion is addressed by the available theorem.

Phantoms on projective space and the failure of a surface rationality criterion

P / partially_solved | AIM 研讨会问题汇编

Consider $D^b(\mathbb{P}^n)$. Take an admissible thick subcategory, $\mathcal{A}$, i.e. a triangulated subcategory closed under taking summands and such that the inclusion has a left (equivalently right) adjoint. If $K_0(\mathcal{A})=0$, is $\mathcal{A}=0$? Such an $\mathcal{A}$ is called a phantom. When $n=1$, it is known that there is no such phantom subcategory. This is related to Caldararu's conjecture on the existence of exceptional collections on projective homogeneous varieties. The answer is no if we replace $\mathbb{P}^n$ by an arbitrary variety (there is a surface counterexample).

If we replace $\mathbb{P}^n$ by another regular surface, is the condition of not having phantom subcategories equivalent to rationality? What if we take $K_0(X) \otimes \mathbb{Q}$?

Positively Curved Projective Varieties - Conjecture 12

O / open | AMR 问题清单汇编

The MRC fibration is defined only by X, and thus it does not reflect information on the boundary Δ. On the other hand, the slope rationally connected quotient (sRC quotient for short), introduced in [Cam16], gives a generalization of MRC fibrations reflecting the boundary Δ (see [Cam04, Cam16]). The following conjecture concerns a structure theorem for sRC quotients. This conjecture was solved when (X, Δ) is a log smooth surface in [CCM19, Theorem 1.6], but it is still open in the general case.

[{[CCM19, Conjecture 1.5]}]

Let (X, Δ) be a klt pair such that X is smooth and $-(K_X +\Delta)$ is nef. Then there exists an orbifold morphism $\rho : (X, \Delta)\rightarrow (R, \Delta_R)$ with the following properties$:$

$\bullet$ (R, Δ_R) is a klt pair such that R is smooth and $c_1(K_R+ \Delta_R)=0$.

$\bullet$ General orbifold fibers (X_r, Δ_r) are slope rationally connected.

$\bullet$ The fibration is locally trivial with respect to pairs, namely, for any small open set $U \subset R$, we have the isomorphism over $U \subset Y$$:$ $$ (\rho^{-1} (U), \Delta)\cong (U, \Delta_R |_U) \times (X_r, \Delta_{X_r}), $$ where X_r is a general fiber of ρ.

Positively Curved Projective Varieties - Conjecture 2

O / open | AMR 问题清单汇编

The following conjecture posed by Yau can be regarded as an analogy of Mok's result for holomorphic sectional curvature.

[Yau's conjecture, {[Yau82, Problem 47]}] If a compact K\"ahler manifold X has positive holomorphic sectional curvature, then X is projective and rationally connected.

背景链接：https://arxiv.org/abs/2211.09153

06169 | AMR-140-0001

Positively Curved Projective Varieties - Problem 1

O / open | AMR 问题清单汇编

MRC fibrations are almost holomorphic by definition, but they are not necessarily represented by holomorphic maps. In fact, there is a projective variety Z with Picard number one, such that Z is uniruled but not rationally connected, which was constructed by Fujita (see [EIM20, Example 6.5] for details). The variety Z admits no non-trivial fibrations (in particular, no holomorphic MRC fibrations) since the Picard number of Z is one. Note that Z has bad singularities: Z is neither log canonical nor $\mathbb{Q}$-factorial. The author does not know an example of smooth projective varieties (or varieties with mild singularities) admitting no holomorphic MRC fibration. Now we suggest the following problem:

When do we choose an MRC fibration to be holomorphic from the ambiguities in the choices of Y?

06177 | AMR-140-0008

Positively Curved Projective Varieties - Problem 8

O / open | AMR 问题清单汇编

The second difference concerns the positivity of fibers F of $\phi:X \to Y$. It was proved in [DPS94] that rationally connected manifolds with nef tangent bundle are always Fano manifolds. However, the same conclusion does not hold for pseudo-effective tangent bundles, since the tangent bundle of the Hirzebruch surfaces is pseudo-effective (see [HIM19, Proposition 4.5]). Then we suggest the following problem:

[{[HIM19, Problem 3.13]}]

Let X be a rationally connected manifold with pseudo-effective tangent bundle. Then is the anti-canonical divisor $-K_X$ big?

Q-Cartierness versus pluricanonical base change

P / partially_solved | AIM 研讨会问题汇编

Let \(f:X\to B\) be a family of surfaces. For a base change \(q:B'\to B\), with \(q_X:X'=X\times_BB'\to X\), say that \(\omega_{X/B}^{[m]}\) commutes with base change if the natural pluricanonical comparison is an isomorphism. Equivalently (using base change for \(\omega\) on the relative Gorenstein locus), \[(q_X^*\omega_{X/B})^{[m]}\ \cong\ q_X^*(\omega_{X/B}^{[m]}). \] Here \(\mathcal F^{[m]}=(\mathcal F^{\otimes m})^{**}\). Kollár's condition asks for this for every \(m>0\) and every base change. Is it equivalent to \(\omega_{X/B}\) being \(\mathbb Q\)-Cartier?

The displayed question itself says only “a family of surfaces,” however. This omitted hypothesis matters. It is also essential to distinguish:

1. the assumption that the original base \(B\) is reduced; and 2. the quantifier over test morphisms \(B'\to B\), where \(B'\) may be nonreduced.

The answer below treats these readings separately. Throughout the characteristic-zero assertions, schemes are locally Noetherian and the families are flat and of finite type.

06227 | AIM-ALGEBRAIC_GEOMETRY-0103

Rational reduction and a prime-to-characteristic sieve for CTO examples

P / partially_solved | AIM 研讨会问题汇编

Plausible reconstruction. Can an irrational variety over a **number field** have a rational specialization in characteristic \(p>0\)? What happens for the examples of Colliot-Thélène and Ojanguren?

It is Problem 3.78 in the section “Rationality in a family” of the AIM workshop list *Rational subvarieties in positive characteristic*. The immediately preceding Problem 3.72 asks about cubic fourfolds “defined over number fields” and their reductions. On that contextual evidence, the most plausible reconstruction is:

This reconstruction is not source-verified, so the exact wording above is preserved. There is a second important ambiguity. “Irrational over a number field” can mean either:

1. not rational over the number field, perhaps becoming rational over its algebraic closure (arithmetic irrationality); or 2. geometrically irrational, and in the parenthetical CTO setting, not even stably rational after base change to an algebraic closure.

The first reading has an elementary affirmative answer. The second is the mathematically substantive reading suggested by the parenthesis.

Throughout the main result below, specialization means a smooth proper model \(\mathcal X\to\operatorname{Spec}R\) over a mixed-characteristic valuation ring, or a smooth proper spread over an open subscheme of the ring of integers of a number field. Rationality of a geometric fiber means rationality after base change to an algebraic closure of its residue field.

Schubert-cycle mobility exponents and general incidence lower bounds

P / partially_solved | AIM 研讨会问题汇编

What is \(K(\alpha)\) for \(\alpha\in N_k(\operatorname{Gr}(k,n))\) a Schubert cycle?

The preceding record on the same AIM page defines \[\operatorname{mc}(\alpha) = \max\{\text{number of general points imposed on an effective cycle of class }\alpha\} \] and displays \[K_{\mathrm{AIM}}(\alpha) = \max\left\{a\in\mathbb R: \limsup_{m\to\infty}\frac{\operatorname{mc}(m\alpha)}{m^a}>0 \right\}. \tag{1} \] For logical safety, throughout this report “max” in (1) is interpreted as “sup”; the endpoint need not be attained for an arbitrary sequence. This does not alter any exact value proved below.

There are two source ambiguities.

1. The symbol \(k\) is used both for the dimension of the planes parametrized by the Grassmannian and for the dimension of the numerical cycles. These are independent quantities. I write \[G=\operatorname{Gr}(d,V)=\operatorname{Gr}(d,N),\qquad \dim V=N,\qquad q=N-d,\qquad D=\dim G=dq, \] and use \(p\) for the dimension of a cycle. 2. The nearby AIM Problem 2.4 says that \(K\) is known to be integral for curves and for \(\operatorname{Gr}(2,N)\). That statement is incompatible with the unscaled exponent (1): for example a big curve on a \(D\)-fold has exponent \(D/(D-1)\). It agrees instead with Brian Lehmann's later normalized cycle Iitaka dimension \[\kappa_{\mathrm L}(\alpha) =(D-p)\sup\left\{a\geq 0: \limsup_{m\to\infty}\frac{\operatorname{mc}(m\alpha)}{m^a}>0 \right\}. \tag{2} \]

Thus, if \(c=D-p>0\) is the codimension, \[\boxed{\kappa_{\mathrm L}(\alpha) =cK_{\mathrm{AIM}}(\alpha)\}. \tag{3} \] Both conventions are reported below. Formula (3), rather than an unacknowledged change of definition, resolves the discrepancy.

The full-dimensional class is exceptional: a positive multiple of \([G]\) contains arbitrarily many points, so its mobility count is infinite. All finite-exponent statements below concern \(0\leq p<D\).

The page currently has the same wording and the same displayed definition (1).

Sharp factoriality threshold and defect-one equality cases

P / partially_solved | AIM 研讨会问题汇编

It comes from Problem 8 (Cheltsov) in the AIM workshop list *Numerical invariants of singularities and higher-dimensional algebraic varieties*.

Let \[X_n\subset \mathbf P^4 \] be a hypersurface of degree \(n\) with finitely many isolated ordinary double points. The record asks:

1. When is \(X_n\) factorial, equivalently \(\operatorname{Cl}(X_n)=\mathbf Z\)? 2. Is \(X_n\) factorial when \[|\operatorname{Sing}X_n|<(n-1)^2? \] 3. For a general projection \[\varphi:\mathbf P^4\dashrightarrow\mathbf P^2, \] can at most \(k(n-1)\) points of \(\varphi(\operatorname{Sing}X_n)\) lie on a plane curve of degree \(k\)?

The source also gives the sharp family \[X_n=\{x f_{n-1}+y g_{n-1}=0\}, \] where \(f_{n-1},g_{n-1}\) are general forms, and states that it has class group \(\mathbf Z\oplus\mathbf Z\). It records the then-known bound \(|\operatorname{Sing}X_n|\leq \frac23(n-1)^2\).

Two corrections are necessary before doing mathematics.

* The source says that factoriality is equivalent to independence of the nodes on forms of degree \(n\). The correct degree is \[2n-5. \] This is Theorem 1.1 and the paragraph following it in Cheltsov--Park [CP06], based on the defect formula of Dimca. * The isolated line “\(S\subset X_n\) smooth of codimension one \(\Rightarrow S\) Cartier” cannot be unconditional: the displayed sharp example contains the smooth plane \(\{x=y=0\}\), which is not Cartier. Cheltsov--Park state the intended scoped version: if \(|\operatorname{Sing}X_n|<(n-1)^2\), every smooth surface in \(X_n\) is cut by an ambient hypersurface.

SL_N fixed-ray quotients and minimal hook complexes

P / partially_solved | AIM 研讨会问题汇编

A theorem of Morton-Samuelson connected the Elliptic Hall algebra at $q=t$ to the Skein algebra of the torus. Categorify this result.

Are there simplifications of the above problem for the $\mathfrak{sl}_n$-quotient invariant?

“The above problem” is Problem 5.1:

Morton-Samuelson [MS, Theorem 5.6] work over $$ \mathscr R=\mathbb Z[v^{\pm1},s^{\pm1},(s^r-s^{-r})^{-1}:r\geq 1] $$ with HOMFLYPT relation $$ L_+-L_-=(s-s^{-1})L_0 $$ and framing curls v^{-1} and v. In their elliptic-Hall convention, which inverts the second Burban-Schiffmann parameter, their isomorphism is at $$ q_{\mathrm E}=t_{\mathrm E}=s^{-2}. \tag{1.1} $$ It sends the torus power-sum curve $P_{\mathbf x}$ to their normalized elliptic-Hall generator $w_{\mathbf x}$.

Write N for the rank parameter, reserving m for the power-sum degree. In the convention above, the quantum $\mathfrak{sl}_N$ specialization is $$ v=s^{-N}. \tag{1.2} $$ Indeed, the contractible unknot then has value $$ \frac{v^{-1}-v}{s-s^{-1}}=\frac{s^N-s^{-N}}{s-s^{-1}}=[N]_s. \tag{1.3} $$ Equivalently, in the common Khovanov-Rozansky notation $a=v^{-1}$, one sets $a=s^N$. In the Heisenberg-category notation of Mousaid-Savage [MouSa], this is $$ z=s-s^{-1},\qquad t_{\mathrm H}=v^{-1}=s^N. \tag{1.4} $$ The elliptic-Hall parameters in (1.1) do **not** change. Thus the $\mathfrak{sl}_N$ operation is not another $q_{\mathrm E},t_{\mathrm E}$ specialization: it is first the coefficient specialization (1.2), and then a Reshetikhin-Turaev tensor quotient (or representation) of the specialized skein category.

Specialization alone is insufficient. At generic s, the actual $\mathfrak{sl}_N$ ribbon category imposes $$ \bigwedge\nolimits^{N+1}V=0,\qquad \bigwedge\nolimits^N V\cong\mathbf 1, \tag{1.5} $$ where V is the vector representation. The second relation distinguishes $\mathfrak{sl}_N$ from the polynomial $\mathfrak{gl}_N$ quotient, in which the determinant remains a nontrivial one-dimensional object.

The invariant in (1.3) is the **unreduced**, framed invariant. A reduced $\mathfrak{sl}_N$ homology requires a marked component and normalizes the unknot differently; it is not naturally an algebra-valued invariant of unmarked torus links. All algebra statements below are therefore unreduced.

Stable-surface properness and an optimal universal tame Kummer index

P / partially_solved | AIM 研讨会问题汇编

Problem 1. 5. (Hassett) Prove the valuative criterion for properness for the moduli stack of stable surfaces in positive characteristic.

Problem 1.5 (Hassett). Prove the valuative criterion for properness for the moduli stack of stable surfaces in positive characteristic.

The exact mathematical sentence is:

The source did not fix a characteristic, a volume, or a smoothability component. Thus its literal scope is all positive characteristics and the full stable-surface moduli problem.

In a modern precise formulation one fixes numerical data, most commonly the volume \[v=K_S^2 \] (and, for pairs, a coefficient set and corresponding Hilbert data), and uses the Kollár condition in the definition of a family. For a discrete valuation ring \(R\) with fraction field \(K\), the existence part of the valuative criterion asks that a stable surface over \(K\) extend to a stable family after replacing \(R\) by the integral closure in a finite extension of \(K\). The uniqueness part is separatedness. Properness is therefore stronger than algebraicity, finite type, separatedness, or projectivity of subspaces already known to be proper.

Stein covers, MRC quotients, and the finite-cover diagonal obstruction

P / partially_solved | AIM 研讨会问题汇编

Let X be a rationally connected 3-fold which is a del Pezzo fibration over $\mathbb P^1$. Is there a component M of the space of sections of the map $X \rightarrow \mathbb P^1$ such that the Stein factorization of $\alpha: M \rightarrow J(X)$ is the MRC fibration of M?

Can we find an example of such a rationally connected 3-fold X with does not admit a decomposition of the diagonal and with the above property for the components of spaces of rational curves on X?

The phrase “with does not” is visibly a typographical error; below it is read as “which does not.” Nothing else in the statement is changed. The record's “Sho” is identified as Sho Tanimoto through Lehmann--Tanimoto's theorem on Stein-factor stabilization [LT24].

There are two minor interpretive points.

1. A component of the section space is usually quasi-projective and may be singular. “Its MRC fibration” therefore means the MRC quotient of a smooth projective model of its Hilbert-scheme closure. 2. “The Stein factorization is the MRC fibration” means that the **connected-fiber morphism** in the Stein factorization is the MRC quotient. It cannot mean the finite morphism to $J(X)$. This distinction is exactly what allows a nontrivial finite cover to evade Voisin's obstruction.

The second question does not specify whether “a decomposition” is meant in the Chow or integral cohomological sense. These are distinguished below. The concrete example of [LT24, Example 10.5] has neither an integral Chow decomposition nor an integral homological (equivalently, in this complex setting, integral cohomological) decomposition.

Termination of klt threefold flips in positive characteristic

P / partially_solved | AIM 研讨会问题汇编

Termination in dimension 3. Do klt flips terminate in dimension 3?

The supplied literature note says:

The record itself does not specify the ground field, projectivity, a base, \(\mathbb Q\)-factoriality, the coefficient field, or whether “terminate” means every sequence or only a specially directed MMP. These omissions matter. The preceding problem 1.1 explicitly works over an algebraically closed field of characteristic \(p>0\), and the AIM workshop description confirms that positive characteristic is the intended setting. I therefore use the following precise absolute version as the main modern reading:

\[\tag{P} \begin{gathered} k\text{ is algebraically closed of characteristic }p>5,\\ (X,B)\text{ is a projective }\mathbb Q\text{-factorial klt threefold with a }\mathbb Q\text{-boundary},\\ \text{and }X=X_0\dashrightarrow X_1\dashrightarrow\cdots \text{ is an arbitrary sequence of }(K_X+B)\text{-flips.} \end{gathered} \]

The question is whether every such sequence is finite. Relative and \(\mathbb R\)-boundary versions are recorded separately below. Hypothesis \(p>5\) is not silently read into the historical question; it is the range where the modern threefold MMP used in the analysis is available in its cleanest form.

The curve cone of the stable genus-zero moduli space and the first symmetric F-curve redundancy

P / partially_solved | AIM 研讨会问题汇编

Problem 5.1. Determine the cone of curves of \(\boldsymbol{\overline M_{0,n}}\).

Inspection of the PDF content stream resolves the typography: immediately before the glyph \(M\), the stream draws a short filled horizontal rectangle at the height of an overline. Thus the mathematical source has an overline that was stored as a vector rule rather than as a font glyph, and both text extractions lost it. The recovered statement is therefore

This reading is also forced by context. The section is headed “Moduli of curves-Birational geometry,” and cites Farkas-Gibney and Gibney-Keel-Morrison, both of which study the proper stable-curve compactification. The usual Kleiman-Mori cone is a cone for a proper projective variety; the open configuration space \(M_{0,n}\) is not the intended object.

For \(n\geq 3\), every stable labeled genus-zero curve has trivial automorphism group: its dual tree is fixed by its labeled leaves, and every component has at least three fixed special points. Consequently \(\overline{\mathcal M}_{0,n}\) is represented by the smooth projective scheme \(\overline M_{0,n}\). There is no stack/coarse numerical discrepancy for the space in the recovered problem. The symmetric quotient \(\overline M_{0,n}/S_n\), used below, does have finite quotient stabilizers; it is treated through pullback and pushforward on real numerical spaces.

06345 | AIM-ALGEBRAIC_GEOMETRY-0111

The exact one-cover differential-form barrier

P / partially_solved | AIM 研讨会问题汇编

Can we improve those techniques to find differential form for lower degree hypersurfaces?

The record has no remarks or bibliography. The original problem-list URL now returns a missing-page response, so the intended antecedents have to be recovered from the section title, the neighboring problem 6.1, the 2016 workshop report, and the papers current at the time of the workshop.

The neighboring problem 6.1 asks about a “very general hypersurface of degree \(d\geq 2\lceil(n+3)/3\rceil\)” in characteristic \(p\). This is Kollár's 1995 bound for an \(n\)-dimensional hypersurface \[X_d^n\subset \mathbf P^{\,n+1}. \] The section title is “New applications of Kollar's and Totaro's techniques.” Thus “those techniques” means:

1. Kollár's mixed-characteristic degeneration of a degree-\(2a\) hypersurface to an inseparable cyclic cover in characteristic \(2\), and the resulting invertible subsheaf of differential forms on a resolution; 2. Totaro's use of the same form, together with a universally \(CH_0\)-trivial resolution and specialization of the decomposition of the diagonal, to obstruct stable rationality.

The intended range is \(n\geq3\), principally the Fano range \(d\leq n+1\). In Kollár's argument the line bundle must be **big**, giving \(d\geq2\lceil(n+3)/3\rceil\). Totaro needs only a nonzero section, giving \[d\geq2\left\lceil\frac{n+2}{3}\right\rceil . \] Accordingly, “lower degree” most naturally means below these linear bounds.

A crucial clarification is that the differential form is not asserted to live on a smooth very general Fano hypersurface. It lives on a smooth resolution \(\widetilde Y\) of a singular inseparable-cover special fiber \(Y\). Passing from such a form to a statement about a different smooth fiber requires a separate specialization theorem and control of the resolution.

The Hilbert--Chow zero-degree face of the surface cone of a Hilbert square

P / partially_solved | AIM 研讨会问题汇编

Effective cones of Hilbert schemes and Moduli Spaces

It is natural to try to compute effective cones in the case of Hilbert schemes or moduli spaces. One natural Hilbert scheme to consider first is the Hilbert scheme of length \(n\) subscheme of a smooth surface \(S\), denoted by \(S^{[n]}\). A great deal is known about these Hilbert schemes. In recent years there has been a lot of exciting work on the effective cones of divisors and curves of the Hilbert schemes \(\operatorname{Eff}^1(S^{[n]})\) and \(\operatorname{Eff}_1(S^{[n]})\). See for example Bayer and Macri's work on Hilbert schemes of K3 surfaces or Huizenga's work on Hilbert schemes of \(\mathbb P^2\). It is then natural to ask how to compute the effective cone of surfaces or the codimension 2 effective cones.

What is the effective cone of surfaces \(\operatorname{Eff}_2(S^{[n]})\)? What is the codimension 2 effective cone \(\operatorname{Eff}^2(S^{[n]})\)? What about higher dimension/codimension?

The spin^c obstruction rules out the proposed threefold

S / solved | AIM 研讨会问题汇编

Does there exist a smooth projective complex threefold \(X\) and \(\gamma\in H^2(X,\mathbb Z/2)\) for which \([\beta_2(\gamma^2)]\ne0\) in \(\mathcal Q_{\beta_2(\gamma)}(X)\)?

The stored AIM record asks for a smooth projective complex threefold \(X\) and \(\gamma\in H^2(X,\mathbb Z/2)\) such that \(\beta(\gamma^2)\in H^5(X,\mathbb Z)\) remains nonzero after quotienting by

\[H^5(X,\mathbb Z)/(H^2(X,\mathbb Z)\,\mathbb Cup\,\beta(\gamma)). \]

The source has two corruptions.

1. The integral Bockstein is the connecting map for \[0\longrightarrow\mathbb Z\xrightarrow{\times2}\mathbb Z \longrightarrow\mathbb Z/2\longrightarrow0. \] The multiplication-by-\(2\) label is missing from the AIM text. 2. Comparison with Antieau--Williams, *The topological period-index problem over 6-complexes*, identifies the string “\(\mathbb{C}up\)” as a corrupted cup product.

Put \(\alpha=\beta_2(\gamma)\in H^3(X,\mathbb Z)\). The intended quotient is

\[\mathcal Q_\alpha(X):= \frac{H^5(X,\mathbb Z)} {H^2(X,\mathbb Z)\smile\alpha}, \qquad H^2(X,\mathbb Z)\smile\alpha =\{u\smile\alpha:u\in H^2(X,\mathbb Z)\}. \]

The recovered question is:

The coefficient-sensitive Antieau--Williams operation uses the Pontryagin square \(P_2(\gamma)\in H^4(X,\mathbb Z/4)\):

\[\widetilde Q(\gamma)= \bigl[\beta_4(P_2(\gamma))\bigr]\in\mathcal Q_\alpha(X). \]

Naturality of the coefficient sequences for \(4\) and \(2\), together with \(P_2(\gamma)\bmod2=\gamma^2\), gives

\[\beta_2(\gamma^2)=2\beta_4(P_2(\gamma)). \tag{1} \]

Thus the displayed AIM class is \(2\widetilde Q(\gamma)\), not the entire secondary obstruction. If it is nonzero, then \(\alpha\) is automatically a nonzero class of exact period \(2\): if \(\beta_2(\gamma)=0\), then \(\gamma\) lifts integrally, so its square lifts integrally and \(\beta_2(\gamma^2)=0\).

The surface cone for split projective-plane bundles over K3 surfaces

P / partially_solved | AIM 研讨会问题汇编

What is the effective cone of surfaces \(\operatorname{Eff}^2(X)\) where \(X\) is a \(\mathbb P^2\)-bundle over a K3 surface?

The preceding record says that \(X\) is a projective bundle \(\mathbb P(\mathcal E)\), and the following record separately asks about split vector bundles. I therefore use the following recovered interpretation.

- \(S\) is a complex projective K3 surface. - \(E\) is a rank-three vector bundle on \(S\). - \(X=\mathbb P_S(E)\) is the Grothendieck projectivization of one-dimensional **quotients**, with projection \(\pi:X\to S\) and tautological quotient \(\pi^*E\twoheadrightarrow \mathcal O_X(1)\). - Since \(\dim X=4\), surfaces have both dimension and codimension two, so \(N_2(X)=N^2(X)\) and the notations \(\operatorname{Eff}_2(X)\) and \(\operatorname{Eff}^2(X)\) refer to the same numerical cone.

A Brauer--Severi \(\mathbb P^2\)-fibration not arising as \(\mathbb P(E)\) is not covered; the surrounding AIM text supports the vector-bundle interpretation. I distinguish the cone generated by effective cycles from its closure, denoting the latter by \(\overline{\operatorname{Eff}}_2(X)\). The workshop summary uses “pseudo-effective” for the closed cone, and this is the convention most likely intended by the problem.

The general problem for arbitrary \(E\) is not solved here. The main proof-level result is a complete answer for split rank-three bundles, followed by a three-ray formula when the K3 surface has Picard rank one.

06372 | AIM-ALGEBRAIC_GEOMETRY-0132

The surface cone of a split rank-three bundle over the projective plane

P / partially_solved | AIM 研讨会问题汇编

In (Fulger 2011, MR2836078) Fulger showed how to compute the effective cone of \(k\)-cycles \(\operatorname{Eff}^k(\mathbb P(\mathcal E)\) of a projective bundle over a smooth curve. In this case the answer can be given in terms of data coming from the Harder-Narasimhan filtration of \(\mathcal E\). However, even in the case where \(X\) is a \(\mathbb P^2\)-bundles over a surface \(S\), it is not known how to compute \(\operatorname{Eff}_2(X)\). It is natural to first consider the case where \(S\) is the projective plane or a K3 surface.

What is the effective cone of surfaces \(\operatorname{Eff}_2(X)\) where \(X\) is a \(\mathbb P^2\)-bundle over \(\mathbb P^2\)?

Tropical Hasse-jet minors and a layered confluent-Vandermonde family

P / partially_solved | AIM 研讨会问题汇编

The source PDF is <https://aimath.org/pastworkshops/degenalggeomproblems.pdf>.

The mathematical request is the following. Given a degree \(d\) and multiplicities \(m_1,\ldots,m_s\) at general points of \(\mathbb P^2\), try to prove the predicted dimension of the interpolation system by adding point conditions until its expected vector-space dimension is one, and then find a single isolated and liftable tropical solution.

There is a convention issue in the source. Put \[N=\binom{d+2}{2},\qquad C=\sum_{i=1}^s\binom{m_i+1}{2},\qquad q=N-C. \] The vector-space virtual dimension is \(q\), whereas the projective virtual dimension is \(q-1\). Thus “expected dimension is 1” must mean vector-space dimension one, equivalently projective dimension zero. When \(q>0\), this is reached by adding \(q-1\) independent simple point conditions.

The source's informal identification with the SHGH conjecture also needs a qualification: the uncorrected assertion “positive expected dimension implies the expected answer” is false in the presence of fixed \((-1)\)-curve components. Standard formulations of SHGH incorporate those components (or first put the system in an appropriate standard form). Section 8 gives the explicit counterexample \(\mathcal L_4(3,3)\) to the literal uncorrected slogan.

06436 | AIM-ALGEBRAIC_GEOMETRY-0215

Vertical tangents and the cubic jumping wall for plane curves

P / partially_solved | AIM 研讨会问题汇编

The displayed map is \[\pi:\mathcal M_{g,n}(\mathbf P^r,\beta)\longrightarrow \operatorname{Conf}(\mathbf P^r,n), \] and the question asks for the possible dimensions of its fibers and vertical tangent spaces, especially when the map is known to be dominant.

There is a genuine notational inconsistency in the PDF: the sentence before the display says that the curve lies in \(\mathbf P^n\), whereas the display, the degree \(d\), and the rest of the problem use the ambient dimension \(r\). I therefore recover the intended ambient space as \(\mathbf P^r\) and write \(\beta=d[\text{line}]\). Since the marked points are ordered, I interpret \(\operatorname{Conf}(\mathbf P^r,n)\) as the open subset of \((\mathbf P^r)^n\) consisting of ordered pairwise-distinct points. Passing to an unordered configuration space is a finite étale quotient away from coincident points and does not change the local tangent calculation.

The source does not specify a compactification or a particular component. The dominance papers cited below use the Brill--Noether component of the stable-map space. On this locus the stable-map moduli problem is locally the incidence problem for embedded curves and marked points. No assertion below extends without modification to nodal maps, ramified maps, multiple covers, or contracted components.

What diagonal and toric-correspondence transforms remember

P / partially_solved | AIM 研讨会问题汇编

What does the Fourier-Mukai transform by either resolution of Δ applied to M tell us about M? More generally what does applying Fourier-Mukai transforms of resolutions of toric subvarieties tell us about the modules apply them to? [e.g. in the spirit of the way we obtain Eagon-Northcott-type complexes for modules]

The archive of the preceding section also resolves an important ambiguity: its Problem 4.1 explicitly calls the two constructions the **Hanlon--Hicks--Lazarev (HHL)** and **Brown--Erman (BE)** resolutions. Thus “either resolution” means those two diagonal resolutions, rather than the later Anderson construction.

The record does not define X or M. In the workshop context, the intended setup is a smooth projective toric variety X, its Cox ring S with irrelevant ideal B, and a finitely generated $\operatorname{Pic}(X)$-graded S-module M. Write $\widetilde M$ for its associated coherent sheaf. The intrinsic Fourier--Mukai statement concerns $\widetilde M$; a free Cox complex obtained by applying Γ_* is additional, presentation-sensitive data. This distinction is essential.

06488 | AIM-GEOMETRY-0217

A Bezout obstruction to the printed divisibility model

O / open | AIM 研讨会问题汇编

It also shows that the page header and all the subsequent text beginning “4. Curvature conditions and hyperbolicity of the geodesic flow” belong to the next section, not to Conjecture 3.2.2.

The immediately preceding paragraph is indispensable context. It defines \[\alpha_{g,G}=\lim_{\deg Y\to\infty}\frac{\deg Y}{\operatorname{cr}(Y)} \] for nonzero free-loop homology classes over a field \(G\), and then supposes, as a “little example,” that for a generator \(X\) of an integral rank-one homology group there are \(a<b<c<d\) such that \[\operatorname{cr}(mX)= \begin{cases} d,&(m,3)=(m,7)=1,\\ c,&3\mid m,\ (m,7)=1,\\ b,&7\mid m,\ (m,3)=1,\\ a,&21\mid m. \end{cases} \tag{1} \] The displayed “conjecture” then gives the proposed coefficient pattern \[\alpha_{g,\mathbb Q}=a,\qquad \alpha_{g,\mathbb F_3}=b,\qquad \alpha_{g,\mathbb F_7}=c,\qquad \alpha_{g,\mathbb F_p}=a\quad(p\ne3,7). \tag{2} \]

As printed, (2) is not a quantified proposition: it specifies neither a metric nor an existence or universal quantifier, and its constants come only from the hypothetical (1). Moreover, (1) is algebraically impossible. Thus this record cannot conservatively be classified as an open conjecture with a determinate truth value.

A boundary-transfer obstruction for 3-Sasakian Kirwan surjectivity

P / partially_solved | AIM 研讨会问题汇编

G

Conjecture 2.1 (C. Boyer) Let S be a complete compact 3-Sasakian manifold with a con-nected compact Lie group G ⊂ Aut (S) acting on S. Consider the 3-Sasakian reduction Sred

(reduction at 0). Then the 3-Sasakian Kirwan map

(S) → H∗(Sred)

is surjective up to the middle dimension. Here we take either Q or R coefficients.

Comment 2.2 (C. Boyer) We know the conjecture is true for S1-reductions of spheres. Note also that in odd dimension, "up to the middle dimension" is all we can hope for. Boyer, Galicki, and Piccinni [BGP02] have constructed some examples of 3-Sasakian quotients for which they don't know how to compute cohomology, and Kirwan surjectivity would be a nice way to get at some cohomology.

Comment 2.3 (C. Boyer and T. Hausel) We might need some additional hypotheses for the nonabelian case, but T. Hausel has some ideas about how to prove something like this for abelian reductions. Namely, the surjectivity in the 3-Sasakian case should be related to surjectivity for hyperK¨ ahler quotients. 3We consider a more specific example. Suppose there is an action of Sp (n + 1) acting on S4n+3. Restrict to an action of a compact subgroup G of this Sp (n + 1). Consider the 3-Sasakian reduction S4n+3 ///G, and additionally assume that this is orbifold. We conjecture that, in this case, the 3-Sasakian Kirwan map is surjective to the middle dimension of the quotient. Here is a tentative idea of the proof. Look at the correponding hyperK¨ ahler quotient. Consider the same group G acting now on Hn+1, which containes S4n+3 as its sphere. Let X

denote now the hyperK¨ ahler quotient. The space X might be singular since G might not have a center. But now suppose there exists some ξ in the center of G so that the hyperK¨ ahler quotient is orbifold. Assume also that the quotient is hypercompact (see Definition 6.9), so the core is middle-dimensional. Then, in this case, the surjectivity of the hyperK¨ ahler Kirwan map should imply the surjectivity (up to middle dimension) of the 3-Sasakian Kirwan map. T. Hausel thinks this should be an elementary argument. C. Boyer and T. Hausel will be pursuing this line of thought after the AIM Workshop ends.

Let \(S\) be a compact complete 3-Sasakian manifold, let a connected compact Lie group \(G\subset\operatorname{Aut}(S)\) act, and let \(S_{\mathrm{red}}\) be the 3-Sasakian reduction at zero. The conjecture is that \[\kappa_{3S}\colon H_G^*(S;K)\longrightarrow H^*(S_{\mathrm{red}};K),\qquad K=\mathbb Q\ \text{or}\ \mathbb R, \] is surjective up to the middle dimension. Comment 2.3 specializes to \(S=S^{4n+3}\subset\mathbb H^{n+1}\), \(G\subset Sp(n+1)\), and proposes passing through a nonzero central-level hyperkähler quotient having a middle-dimensional core.

If \(L=S^{4n+3}///G\) has dimension \(4m-1\), this report uses “through the lower middle” to mean degrees \[q\leq \left\lfloor\frac{4m-1}{2}\right\rfloor=2m-1. \] The phrase in the source does not separately specify whether its endpoint is inclusive; the result below isolates exactly what happens in that endpoint degree.

A cohomological target and periodic certificates for contact dissipation

P / partially_solved | AIM 研讨会问题汇编

Let \((M,\xi)\) be a closed contact manifold and let \(\varphi\in\operatorname{Cont}(M,\xi)\). Suppose that the induced action on contact homology \(CH(M,\xi)\) is hyperbolic, in a sense still to be defined. Then \(\varphi\) is strongly dissipative: there is no smooth \(\varphi\)-invariant volume form.

The bracketed comments and, in particular, the warning that “hyperbolic” still has to be formulated are in the source itself.

The recovered conjecture is:

The source then places the conjecture in the “functor” from smooth topology to contact topology: a manifold gives its unit cotangent bundle, a submanifold gives its unit conormal, and a diffeomorphism gives a lifted contactomorphism. The question asks how much smooth information survives these constructions.

Throughout the mathematical results below, \(M^{2n+1}\) is closed and \(\xi\) is cooriented, \(\alpha\) is a positive contact form with \(\ker\alpha=\xi\), and \(\varphi\) preserves the coorientation. This is the standard setting for the contact-homology algebra and for Polterovich's paper. For a coorientation-reversing map, an invariant volume for \(\varphi\) would also be invariant under \(\varphi^2\), so obstructions may instead be applied to the square.

06495 | AIM-GEOMETRY-0305

A collision-stable global-residue reduction for the Higgs-moduli Bethe formula

P / partially_solved | AIM 研讨会问题汇编

For the fixed-determinant, trace-free Higgs moduli space \(\mathcal M^d_{\mathrm{Dol}}(SL(n,\mathbb C))\), its circle-equivariant volume \[\oint_{\mathcal M}e^\alpha :=\sum_{F\subset \mathcal M^{\mathbb C^*}} \int_F\frac{e^{\alpha|_F}}{e_{\mathbb C^*}(N_F)}, \] and, more generally, all equivariant intersection numbers, admit an iterated-residue expression \(BA(y_1,\ldots,y_n)\). Its poles divide into poles indexed by ordered partitions \(n=\lambda_1+\cdots+\lambda_k\) and poles satisfying Bethe-Ansatz equations. The residue at a partition pole equals the localization contribution of the corresponding fixed component, while minus the sum of the Bethe residues equals the equivariant volume.

Here the curve is a smooth projective complex curve of genus \(g\), the Higgs field is scaled by \(\mathbb C^*\), and one normally assumes \(\gcd(n,d)=1\) to stay in the smooth stable setting. The source calls the first quantity an integral even though the space is noncompact; it is the formal equivariant integral defined by its fixed-point sum.

The database field accidentally continues past the heading “6.5 Arithmetic approach” and includes Theorem 6.17 and later definitions. Comparison with the source PDF shows that this material is not part of Conjecture 6.16 and is not treated here. The source also writes “Nekrasov--Shatasvili--Moore”; the primary paper and later references use **Moore--Nekrasov--Shatashvili**.

The AIM statement does not display the higher-rank function \(BA\), specify an order for the iterated residues, state a contour/summation prescription for the generally infinite Bethe set, or give a compactification and its boundary terms. Those omissions matter mathematically.

A conformal-factor cocycle proof of fact 2

S / solved | AIM 研讨会问题汇编

Problem 18. Deduce fact 2 from fact 1 or vice versa. Alternatively, construct a Lie algebraic proof of fact 2.

The beginning of that field is

The two facts, supplied by the immediately preceding source record and verified against the official source, are as follows. Let \(n=2m\), let \(\delta\) be a flat Euclidean metric, and let \(\widehat\delta=\Omega^2\delta\).

- **Fact 1.** The critical power \(P_\delta=\Delta_\delta^m\), regarded as an operator from weight-zero functions to conformal densities of weight \(-n\), is conformally invariant on flat space. In scalar representatives, \[P_{\Omega^2\delta}f=\Omega^{-n}P_\delta f \] whenever both sides are expressed in flat scales. - **Fact 2.** If \(\Omega^2\delta\) is itself flat, then \[\Delta_\delta^m\log\Omega=0. \]

The AIM source works locally, with \(\Omega>0\), and calls \(\Delta\) the ordinary Euclidean Laplacian. These are the assumptions used below. The statement only has the displayed differential-operator meaning in even dimension; odd-dimensional fractional operators are outside its scope.

A convention-safe reduction for cubic integrals on the two-torus

P / partially_solved | AIM 研讨会问题汇编

Conjecture 10.2.1 ([Bo-Ko-Fo1995]). If the geodesic flow of a Riemannian metric on the torus \(T^2\) admits an integral that is polynomial of degree 3 in the velocities, then the metric admits a Killing vector field.

If a smooth Riemannian metric on \(T^2\) has a nonzero homogeneous cubic first integral, then it has a nonzero homogeneous linear first integral.

The mathematical record begins with the following statement.

The paragraphs in the record through the proposed odd/even degree analogues belong to Section 10.2 of the source. They explain that a Killing field gives a linear integral whose cube is cubic, that homogeneous velocity components of a geodesic-flow integral are separately integrals, and that “degree” in the accompanying table means the *smallest degree of a nontrivial integral*. The material beginning “10.3.

There are two suppressed conventions in the displayed conjecture. The intended integral is nontrivial (additional to the energy), and “degree 3” means exact fibre degree, not degree at most three. Equivalently, after taking the top homogeneous part, the intended assertion is:

For a linear function \(L=X^i p_i\) on \(T^*T^2\), the identity \(\{H,L\}=0\) is equivalent to \(\mathcal L_Xg=0\), so this is exactly the Killing-vector conclusion. Smoothness is enough for the elementary results below. Analyticity is stated separately where a cited global theorem needs it.

A fixed-component formula for the hyper-compact signature

P / partially_solved | AIM 研讨会问题汇编

The recovered statement of Conjecture 6.10 is as follows. Put

\[K=\mathbb Q(u),\qquad \widehat H^*_{S^1}(M)=H^*_{S^1}(M;\mathbb Q)\otimes_{\mathbb Q[u]}K, \]

and order K by declaring a nonzero rational function positive when its leading coefficient (equivalently its sign for $u\gg0$) is positive. For a circle-compact M, Hausel--Proudfoot define integration by fixed-set localization and the pairing

\[B_M(\alpha,\beta)=\int_M\alpha\beta. \]

The intended conjecture is that if M^{4n} is hyper-compact and \(\sigma(M)\) is the signature of this localized pairing, then \((-1)^n\sigma(M)\ge0\).

Two corrections are necessary. First, the AIM Definition 6.9 immediately preceding the record says “finitely many critical points.” Read literally, this is inconsistent in positive dimension with the weight-one symplectic hypothesis and the existence of a minimum (Proposition 5.1 below). Hausel's primary 2003 paper instead defines hyper-compactness using a proper Hamiltonian with a minimum and explicitly allows fixed components $F_1,\ldots,F_f$; the later semiprojective formulation also has projective fixed components. Second, on odd cohomology cup product is alternating, not symmetric. The abelianization Theorems 6.12--6.13 are boundary context, not additional problems addressed here.

A flag certificate for abstract Kirwan surjectivity

P / partially_solved | AIM 研讨会问题汇编

Recovered Conjecture 5.2 (G. Landweber). Let a torus \(T\) act on a smooth manifold \(M\), and let \(\Phi:M\to\mathfrak t^*\) be an abstract moment map: for every closed subgroup \(H\subset T\), the projection \(\Phi_H:M\to\mathfrak h^*\) is constant on each connected component of \(M^H\). Assume \(\Phi\) is nondegenerate, meaning that for every \(\xi\in\mathfrak t\), \[\operatorname{Crit}(\Phi^\xi)=\{x\in M:\xi_M(x)=0\} \] and \(\Phi^\xi=\langle\Phi,\xi\rangle\) is Morse--Bott. For a regular value, translated to \(0\), the conjecture asks whether restriction \[\kappa:H_T^*(M)\longrightarrow H_T^*(\Phi^{-1}(0)) \] is surjective.

Recovered Comments 5.3--5.5. The workshop notes say that the compact \(S^1\) case is proved in GGK, while the GGK proof for higher-dimensional tori has an error. They ask whether local symplectic forms can replace global symplectic geometry. GGK Theorem G.22 gives such a form near an orbit when the abstract moment map is nondegenerate and the symplectic slice admits an invariant complex structure.

A four-dimensional curvature-quadratic slice of the global conformal invariant decomposition

P / partially_solved | AIM 研讨会问题汇编

Conjecture 2. Any \(S\) as above may be written \[\mathrm{const}\cdot Q+L+V, \] where \(V\) is an exact divergence.

The words “as above” are essential. The surrounding text first asks in Conjecture 1 for a **natural \(n\)-form** \(S\) whose integral is conformally invariant, and then introduces Conjecture 2 as the stronger assertion that the third term can be chosen to be an exact divergence. The PDF also makes the following conventions explicit.

* \(M\) has even dimension \(n\). The primer starts with \(M\) oriented; equivalently, one can use scalar densities and omit orientability. * All local invariants in this discussion are treated as density-valued. In scalar notation they have conformal weight \(-n\), so that \(P(g)dV_g\) has weight zero under constant rescaling. The filtration immediately after Conjecture 2 uses monomials in curvature and covariant derivatives satisfying \(k_\nabla+2k_R=n\). * For \(\widehat g=e^{2\omega}g\), the critical \(Q\)-curvature density satisfies \(\widehat Q=Q+P_n\omega\), with \(P_n\) formally self-adjoint and annihilating constants. Hence \(\int_M Q\) is conformally invariant on a closed manifold. * A local conformal invariant \(L\) is a natural density fixed pointwise by conformal rescaling. An exact divergence is \[V=(\nabla_iT^i)dV_g=d(\iota_TdV_g) \] for a natural vector field \(T\).

The conjecture itself does not repeat “compact without boundary.” This is recovered from the surrounding integral discussion and is necessary for an exact divergence to integrate to zero without a boundary correction. In this report, **closed** means compact without boundary. The exact literal phrase “natural \(n\)-form” is not given a formal category in the workshop notes; this ambiguity matters for the present-day status in Section 2.

A global quantitative square-stability bound for rectangles

P / partially_solved | AIM 研讨会问题汇编

Determine the best lower bound on \[J(\Omega):=\frac{\lambda _1(\Omega)}{h(\Omega)^2} \] among planar convex open sets, conjecturing \[J(\Omega)\geq J(Q):=\frac{2\pi^2}{(2+\sqrt\pi)^2} =1.3870172735\ldots, \] with equality, up to similarities, only for a square. It also asks whether a minimizer is polygonal and suggests first studying polygons through the geometry of their Cheeger sets.

Two notational repairs are necessary. For a measurable set \(E\), \(|\partial E|\) must mean the ambient De Giorgi perimeter \(P(E;\mathbb R^n)\), not the measure of the topological boundary and not the relative perimeter in \(\Omega\). Thus \[h(\Omega)=\inf_{\substack{E\subset\Omega,\ |E|>0\\E\text{ of finite perimeter}}} \frac{P(E;\mathbb R^n)}{|E|}. \] The functional formulation in the source also needs either nonnegative test functions or an absolute value in the denominator: \[h(\Omega)=\inf_{0\neq u\in C_c^\infty(\Omega)} \frac{\int_\Omega |\nabla u|}{\int_\Omega |u|}. \] Without this repair, sign-changing functions can make the displayed denominator zero or negative. The spectral quantity is \[\lambda _1(\Omega)=\inf_{0\neq u\in H_0^1(\Omega)} \frac{\int_\Omega |\nabla u|^2}{\int_\Omega u^2}. \]

The source calls the square prediction "Ilias Ftouhi's conjecture." The primary literature checked attributes the conjecture to Enea Parini; Ftouhi subsequently improved the universal planar-convex lower bound.

06528 | AIM-GEOMETRY-0362

A Helmholtz test and a scale-descent obstruction for conformal primitives

P / partially_solved | AIM 研讨会问题汇编

Problem 5b. What characterizes such curvature invariants? A related problem is posed by T. Branson: On \(M^n\), \(Q\)-curvature is a local invariant (of density weight \(-n\)) which does not have a conformal primitive. The local invariants that have conformal primitives form a vector subspace, say \(\mathcal L'\), of the space of local invariants \(\mathcal L\). Thus the quotient space \(\mathcal L/\mathcal L'\) is the space which measures “how many things” do not have a conformal primitive. There are also local conformal invariants, \(\mathcal L''\), say.

A lift-dependent Martin formula and a sharp middle-degree obstruction

P / partially_solved | AIM 研讨会问题汇编

Question 2.4 (T. Hausel) Is there a Martin theorem for 3-Sasakian quotients? What about for Sasakian quotients? Getting a Martin-type formula requires Kirwan surjectivity, but perhaps surjectivity "up to middle dimension" would be enough to get a Martin-type theorem for the 3-Sasakian case.

Comment 2.5 (J. Munn) Martin's theorem probably should be extendable analytically in the polysymplectic case. Since 3-Sasakian manifolds can arise as boundaries of hyperK¨ ahler manifolds, we can look at compact cohomology based on the 3-Sasakian manifold (regarded as a boundary). Here we can ignore cone points and do integration theory.

A mixed gluing ledger for higher-genus relative symplectic field theory

P / partially_solved | AIM 研讨会问题汇编

Can one construct a rigorous relative SFT-type invariant which includes holomorphic curves of arbitrary genus, rather than only genus-zero (“rational”) curves, and can such a theory illuminate Gopakumar--Vafa/BPS structures?

The source record says:

It is not part of Question 1.31.** The statement above is the complete text of Question 1.31 in the official source.

The note itself admits that substantial context is missing. It therefore does not specify:

- the relative geometric object (a Legendrian, a Lagrangian cobordism, a contact manifold with boundary, or something else); - the generators, coefficients, grading, or completion; - the precise relation sought with Gopakumar--Vafa invariants.

The preceding Question 1.30 concerns knots and their Legendrian conormal tori, and other passages in the workshop notes discuss relative contact homology as a module over absolute contact homology. This makes a Legendrian/Lagrangian-relative reading plausible, but it does not prove that this was the unique intended meaning. No stronger reconstruction is asserted.

The minimal justified mathematical question is:

06536 | AIM-GEOMETRY-0407

A Morita shadow of contact homology and a dualizability obstruction

P / partially_solved | AIM 研讨会问题汇编

Question 1.11. Generalizing the theme of computing things, one could try to extend symplectic field theory to an “extended field theory”. Recall that a TQFT assigns to an \(n\)-manifold (possibly with some extra structure) a number, and to an \((n-1)\)-manifold a vector space, satisfying various axioms which allow one to compute the invariant of an \(n\)-manifold by cutting it up along \((n-1)\)-manifolds. But then one is left with the problem of understanding the \((n-1)\)-dimensional invariant. In an extended TQFT, one can compute the latter by cutting along \((n-2)\)-dimensional manifolds, to each of which is assigned a category. (One can continue by assigning 2-categories to \((n-3)\)-manifolds and so forth, so that the manifolds get simpler while the theory gets more complicated...) Now the question is, how can one do this for SFT?

06537 | AIM-CONVEX_GEOMETRY-0009

A necessary moment order and a scale obstruction

P / partially_solved | AIM 研讨会问题汇编

Let the k-th moment tensor of a convex body be the k-th moment tensor of the uniform distribution on it. For any positive integer t, is there $k=k(t)$, independent of d, such that the map taking a d-dimensional polytope with d^t facets to its first k moment tensors is injective?

It then records:

1. [GLPR] an n-vertex d-polytope can be recovered from $O(dn)$ axial moments along d random directions; 2. [FJK] a parallelepiped can be estimated efficiently from the first four moment tensors; 3. [AGR] a simplex can be estimated efficiently from the first three moment tensors.

Finally it asks for an efficient reconstruction algorithm, for $1/10$ Hausdorff accuracy, both from moment tensors and from polynomially many uniform samples.

The repairs and ambiguities are:

- “dt facets” in the extraction is d^t facets in the PDF. - The PDF prints ordinary $O(dn)$, not an exponent. The underlying Gravin--Lasserre--Pasechnik--Robins theorem is stated as $O(Nd)$ axial moments for N vertices in $d+1$ generic directions; the workshop text says d random directions. - In the algorithmic paragraph the PDF says “time polynomial in n” and “sample size polynomial in n,” although the ambient dimension in the question is d, and n appeared only locally as the number of vertices in item (a). This is preserved as printed. The likely intended complexity variable is d (equivalently polynomial in the facet count d^t for fixed t), but that reconstruction is not certain. - Taken literally, the $t=1$ class consists of full-dimensional d-polytopes with exactly d facets and is empty: every d-polytope has at least $d+1$ facets. The substantive regime is therefore $t\ge2$, unless “d^t” was intended only as asymptotic shorthand.

For a full-dimensional compact polytope $P\subset\mathbb R^d$, write $$ M_j(P)=\frac1{\operatorname{vol}(P)}\int_P x^{\otimes j}\,dx \in \operatorname{Sym}^j(\mathbb R^d). $$

A non-Morse obstruction certificate and the contact sphere

P / partially_solved | AIM 研讨会问题汇编

Question 5.8 (E. Lerman) Can we prove Kirwan surjectivity without Morse theory? The motivation for this question comes from the fact that two fundamental results in the theory of symplectic moment maps - connectedness and convexity, which were originally proved using Morse theory have an alternative proof [CDM88]. This alternative approach works well in the contact setting (equivalently in the setting of symplectic cones) where Morse theory fails. The reasons for the failure in the contact setting are due to the fact are that the contact moment maps are not Morse and that there is no relationship between critical points and isotropy groups. In the equivalent setting of symplectic cones the moment maps are not proper.

Comment 5.9 (E. Lerman) As mentioned in

A normalized lattice transport problem and a product-stability bound

P / partially_solved | AIM 研讨会问题汇编

Choose $\Lambda \subseteq \mathbb R^d$ to minimize the Wasserstein (optimal transport) distance form $\sum_{x \in \Lambda} \delta_x$ to the Lebesque measure.

The exact AIM record asks:

The source remark says that for the Wasserstein 2-distance in $\mathbb R^2$ the unique minimizer is the triangular lattice, citing Bourne--Peletier--Theil [BPT14].

There are two more substantive omissions. Ordinary W_p is a distance between finite measures of the same mass (usually probability measures), whereas both dx and $\sum_{\lambda\in\Lambda}\delta_\lambda$ have infinite mass on $\mathbb R^d$. Moreover, if $V=\operatorname{covol}(\Lambda)$, then the counting measure has mean mass density $1/V$. Thus unit atoms match dx only when $V=1$, and the scale must be fixed or the lattice can simply be shrunk.

The natural recovered problem is therefore the following. For $p\geq1$ and a full-rank lattice $\Lambda\subset\mathbb R^d$ of fixed covolume V, let

\[\mathbb{T}_\Lambda=\mathbb R^d/\Lambda, \qquad m_\Lambda=V^{-1}dx, \]

where the torus has the quotient (periodic/geodesic) Euclidean distance. Minimize

\[\mathcal E_p(\Lambda) :=W_{p,\mathbb{T}_\Lambda}^{p}(m_\Lambda,\delta_0). \tag{1} \]

Equivalently, (1) is the transport cost per unit volume for a Λ-equivariant transport from dx to the mass-matched atomic measure

\[V\sum_{\lambda\in\Lambda}\delta_\lambda. \]

For the unit atoms appearing literally in the AIM record one takes $V=1$. Minimizing W_p or its p-th power $\mathcal E_p$ gives the same lattices, but their numerical values are different.

A one-coordinate unlockability certificate for open chains in three-space

P / partially_solved | AIM 研讨会问题汇编

2. (Streinu) Same as the previous question, but with an open arm in \(\mathbb R^3\), and \(\ell_1=\ell_2=\cdots=\ell_n\). **Question:** Is the space of non-intersecting configurations connected?

The original AIM problem-list PDF reads:

The preceding item defines the self-intersection locus for closed polygons. More decisively, the AIM workshop report restates Item 2 as the three-dimensional Carpenter's Rule problem: can an arbitrary open chain of unit-length bars be unfolded to a straight line by non-crossing motions? Thus the intended object is an **equilateral open polygonal chain with universal joints**, not a fixed-angle chain and not merely a topological arc.

The source does not specify whether rigid motions have been quotiented out or whether tangential contact is admitted. The standard strict model is adopted below; the convention issue is discussed in Section 3.

A parameterized twelve-contact case and full dodecahedral shell formula

P / partially_solved | AIM 研讨会问题汇编

Its exact `problem` field is:

Taken by itself, this record does not define a soft packing, state its parameter, or specify which of two density ratios is intended. The section introduction on the original AIM webpage supplies the missing first part: a soft ball is a concentric pair consisting of a unit ball and a ball of radius $1+\lambda$, where $\lambda>0$; the unit balls have disjoint interiors, while density means the fraction of space covered by the radius-$1+\lambda$ balls.

The precise framework was introduced before the 2016 AIM workshop by Bezdek and Lángi. Put $B=B^3=\{x\in\mathbb R^3:|x|\leq1\}$, let $C=\{c_i\}\subset\mathbb R^3$ be locally finite with $|c_i-c_j|\geq2$, and set

$$ P_\lambda=\bigcup_i\bigl(c_i+(1+\lambda)B\bigr). $$

The cores c_i+B form an ordinary unit-ball packing; the enlarged balls form a soft packing with *soft parameter* (originally, *penetrating constant*) λ. Its upper global soft density is

$$ \overline\delta(P_\lambda) =\limsup_{R\to\infty} \frac{\operatorname{vol}(P_\lambda\cap RB)} {\operatorname{vol}(RB)}, \qquad \overline\delta_3(\lambda)=\sup_P\overline\delta(P_\lambda). $$

For a center translated to the origin, its Voronoi cell is

$$ V=\{x:|x|\leq |x-c_j|\text{ for every other center }c_j\}. $$

Writing $s=1+\lambda$, the local soft density intended by the AIM wording is

$$ \overline\rho_s(V)= \frac{\operatorname{vol}(V\cap sB)}{\operatorname{vol}(V)}. \tag{1} $$

This is distinct from the companion *truncated density*

$$ \rho_s^{\rm tr}(V)= \frac{\operatorname{vol}(B)}{\operatorname{vol}(V\cap sB)}. \tag{2} $$

Let D be the regular dodecahedron circumscribed about B, meaning that B is its insphere and its inradius is one. Its circumradius and edge-midpoint radius are

$$ R_D=\sqrt{15-6\sqrt5}=\sqrt3\tan\frac\pi5 =1.258408572\ldots, \qquad q_D=\sqrt{\frac{5-\sqrt5}{2}} =1.175570505\ldots. \tag{3} $$

$$ N_D(s)=\operatorname{vol}(D\cap sB),\qquad \overline\tau_D(\lambda)=\frac{N_D(1+\lambda)}{\operatorname{vol}(D)}. \tag{4} $$

The strongest literal recovery of the AIM statement is the cellwise conjecture

$$ \boxed{\quad \overline\rho_{1+\lambda}(V)\leq\overline\tau_D(\lambda) \quad\text{for every bounded Voronoi cell }V, \quad 0<\lambda<R_D-1. \quad} \tag{SDC-local} $$

Bezdek and Lángi's 2015 paper instead explicitly asks the global inequality

$$ \boxed{\quad \overline\delta_3(\lambda)\leq\overline\tau_D(\lambda). \quad} \tag{SDC-global} $$

The local statement implies the global one for periodic packings (and under standard uniform boundary control more generally), but they should not be silently identified. A regular dodecahedron does not tile space; it is a local comparison cell, not a claim that every cell in an optimizing infinite packing is dodecahedral.

The 2015 source prints $0<\lambda<R_D$, although the inflated radius is $1+\lambda$. Once $\lambda\geq R_D-1$, one has $D\subset(1+\lambda)B$ and $\overline\tau_D(\lambda)=1$, so the soft-density inequality is merely the tautology that a covered fraction is at most one. The 2025 formulation uses the meaningful range $0<\lambda\leq R_D-1=0.258408572\ldots$.

A phase-enriched tropical certificate for Kwon's chamberwise real counts

P / partially_solved | AIM 研讨会问题汇编

A.11 Real Gromov--Witten invariants and tropical geometry. Background: G. Tian and S. Kwon recently defined a real Gromov--Witten invariant on each chamber in the real Chow cycles' parameter space when the target space is CP 2. That is a real enumerative invariant, counting the number of intersection points of pull back of real Chow cycles in the real part of the Kontsevich's moduli space of stable maps from genus 0 curves. To use Mikhalkin's work on counting plane rational nodal curves, we showed that the classical nodal Severi variety is embedded as a Zariski open dense subset in the Kontsevich's moduli space. Question: It will be interesting to develop techniques to calculate real Gromov--Witten invariants by using tropical geometry. (contributed by Seongchun Kwon)

A pole-safe dual-paired Ewald reduction for the remaining D4 conjecture

P / partially_solved | AIM 研讨会问题汇编

Recovered Conjecture 1. For every real $s>0$, the covolume-one forms of D_4,E_8, and the Leech lattice globally minimize the analytically continued Epstein zeta function among covolume-one lattices in their respective dimensions.

\[E_L(s)=\sum_{0\ne x\in L}|x|^{-2s}, \]

initially for $\operatorname{Re}s>n/2$ and by meromorphic continuation otherwise. “These lattices” means

\[D_4\quad(n=4),\qquad E_8\quad(n=8),\qquad \Lambda_{24}\quad(n=24), \]

each scaled to covolume one. Thus the reconstructed conjecture is:

There is an essential qualification. $E_L(s)$ has a common simple pole at $s=n/2$, so it has no finite value there. At the pole, the only mathematically meaningful version of the conjecture is minimization of the finite part

\[\operatorname{FP}E_L(n/2)=\lim_{s\to n/2} \left(E_L(s)-\frac{\pi^{n/2}/\Gamma(n/2)}{s-n/2}\right). \]

This convention agrees, up to a positive dimension-dependent factor and an additive constant, with the height of the corresponding flat torus.

This report owns Conjecture 1 only. It does not attempt to answer neighboring Question 0 or Problem 2.

A semi-flat period and weighted-geodesic reduction for fibred special Lagrangians

P / partially_solved | AIM 研讨会问题汇编

1. Elliptically fibred CY manifolds and their SLAG submanifolds. What can be said about SLAGs in a CY 3-fold that happens to be elliptically fibred or K3 fibred? Are there nice characterizations? Are such SLAGs fibred? More specifically, if a real six-manifold M^6 is a Calabi--Yau threefold fibred over $\mathbb{CP}^1$ by K3 surfaces, can a real three-dimensional special Lagrangian L^3 be assembled over a curve $C\subset\mathbb{CP}^1$ from real two-tori in the K3 fibres? In an adiabatically collapsing family $M_t\to B$, what is the limiting base curve, and can the limit control the special Lagrangians?

The primary three-page PDF is an AIM Workshop on Calibrations problem list compiled by Spiro Karigiannis in 2006. Lines 9--30 of page 1 form one numbered item:

The primary source starts a distinct numbered item “2. Yau--Zaslow number for K3 manifolds” at line 31, followed by separately numbered items on Bäcklund transformations, G_2 Floer analogues, Bernstein problems, geometric measure theory, special Lagrangian cones, and regularity. Those later items are preserved as source provenance but are outside the mathematical ownership of this attempt.

There is also an apparent source typo in the fifth bullet. It first defines B as the base and $C\subset B$ as the curve, then asks “What is the curve B in the limit?” The coherent reading is “What is the curve C in the limit?” Both the literal wording and this reconstruction are recorded.

06567 | AIM-GEOMETRY-0026

A theta compactification and tropical obstructions for the rank-one braid

P / partially_solved | AIM 研讨会问题汇编

How does this relate to compactifications coming from tropical geometry?

The pronoun “this” is not self-contained. The immediately preceding records ask:

- 4.1 for a natural compactification of a braid variety whose smaller strata have cluster structures; - 4.2 whether brick manifolds can be obtained cluster-theoretically; - 4.3 how the construction relates to subword complexes.

The AIM workshop report confirms this reconstruction. For a positive braid word \(\beta\), it considers \[X(\overline\beta;\delta(\beta))\subset\operatorname{brick}(\beta), \] and reports a proposed cluster compactification with potential \[W=z_1+\cdots+z_\ell. \] Thus problem 4.4 asks how the word-relative brick/cluster compactification and its subword strata compare with compactifications built from tropical data.

There are at least four mathematically different meanings of “coming from tropical geometry,” so the comparison is meaningless unless they are separated:

1. Tevelev’s closure of a very affine variety in a toric variety; 2. a GHKK theta compactification obtained by taking Proj of a positive-set theta algebra; 3. a toric degeneration associated with a seed valuation or Newton--Okounkov body; 4. a toric variety constructed from an ordinary Newton, moment, or brick polytope.

The main result below makes all four distinctions explicit for the nontrivial braid \(\beta=\sigma_1^3\).

A topological certificate for Kirwan-type restriction

P / partially_solved | AIM 研讨会问题汇编

Which topological and Morse-theoretic properties of an equivariant map $F:M\to V$ suffice to make the restriction $H_G^*(M)\to H_G^*(F^{-1}(0))$ surjective, and what extra issue arises when $V=\mathfrak g^*\otimes\mathbb R^3$ for a hyperkähler moment map?

This record is Question 5.1, attributed to E. Lerman, in the AIM workshop list *Moment maps and surjectivity in various geometries*.

I reconstruct `hyperK¨ ahler` as *hyperkähler*, `M.Note` as `M. Note`, `6the` as a page-number artifact followed by `the`, and $R2,S1,\mathfrak g\!\ast,M H,M G$ as $\mathbb R^2,S^1,\mathfrak g^*,M^H,M^G$. The last clause should be read componentwise: for $\xi\in\mathfrak g$, the critical set of $\langle\mu,\xi\rangle$ is the zero set of the infinitesimal vector field ξ_M, not generally the single set M^G. This agrees with Ginzburg--Guillemin--Karshon (GGK).

The precise mathematical question addressed here is:

06572 | AIM-GEOMETRY-0361

A variational test and a family of conformal primitives

P / partially_solved | AIM 研讨会问题汇编

n

Problem 5a: How to decide which curvature invariants have a conformal primitive? For example on manifold M, we have Δ(J n/ 2-1) has 2

Jn/ 2 as a conformal primitive, i.e.

(ω) = Δ(Jn/ 2-1)for all smooth function ω on M, see "Origins, applications and generalizations of the Q-curvature" by T. Branson and R. Gover. Available through http://www.aimath.org.

The displayed formula in the problem list still suppresses a necessary integral pairing on its right-hand side: the derivative of a functional in direction ω is a number, whereas $\Delta(J^{n/2-1})$ is a function.

The cited Branson--Gover article removes the ambiguity. It states

\[J^\bullet=-2\omega J+\Delta\omega \]

\[\left(\int_M J^{n/2}\,dv_g\right)^\bullet(\omega) =\frac n2\int_M\omega\,\Delta(J^{n/2-1})\,dv_g. \]

Thus the verified reconstruction of the example is

\[\boxed{ \left.\frac{d}{dt}\right|_{0} \int_M\frac2n J_{g_t}^{\,n/2}\,dv_{g_t} = \int_M\omega\,\Delta_g(J_g^{\,n/2-1})\,dv_g, \qquad g_t=e^{2t\omega}g.} \]

The cited article works primarily in even dimension. To make the integration by parts literal, this report assumes that M^n is a smooth closed Riemannian manifold and that $n\geq4$ is even. The conventions are

\[J=\frac{R}{2(n-1)},\qquad \Delta=-\nabla^i\nabla_i=d^*d,\qquad (dv_g)^\bullet=n\omega\,dv_g. \]

With this nonnegative Laplacian convention, the displayed formula for $J^\bullet$ is correct. All primitive identities below are identities of integral pairings against ω, not pointwise identities between a number and a scalar field.

Abstract tropical spaces and the actual fibers of phase tropicalization

P / partially_solved | AIM 研讨会问题汇编

This record is Section C.2, “Basic definitions,” in the 14 January 2004 AIM workshop report *Amoebas and Tropical Geometry*. It records workshop proposals and questions, not a settled definition. The questions are:

1. What should an abstract tropical variety or abstract idempotent variety be, including local models and gluing maps? 2. For a non-Archimedean variety, how should valuation, phase, tropical, complex tropical, and real tropical images be distinguished? 3. When is a complex/phase tropical limit homeomorphic or homotopy equivalent to a nearby classical fiber? 4. Is there a tropical Hodge theory compatible with classical limiting Hodge theory? 5. Can patchworking be refined to retain information about an individual hypersurface, and how should maps and bundles be defined?

The source also prints: “The fiber of the projection from such a complex tropical variety to the corresponding tropical variety is a torus.” That statement is false in general. The modern fiber is a coamoeba (or its closure, depending on convention) of an initial degeneration. Section 5 gives the exact binomial case, and Section 7 gives a tropical-line counterexample.

Affine conformal densities from form Q-operators

S / solved | AIM 研讨会问题汇编

Problem 34: Construct other natural tensor-densities which transform according to (43). (Note that any solution yields a conformally invariant natural operator \(L\).) Solutions to

Solutions to Problem 34 have a role to play in the problem of characterizing the \(Q\)-curvature and the GJMS operators.

Equation (43) is not contained in this record. The immediately preceding canonical record and the official AIM source verify that it is \[N^{\widehat g}=N^g+L^g\omega, \qquad \widehat g=e^{2\omega}g. \tag{43} \] Here \(N^g\) is a natural Riemannian tensor-density and \(L^g\) is a universal linear differential operator. The official source verifies that the truncated final words continue as a separate sentence:

The following paragraph, “Generalizations of \(Q\),” is explanatory material, not a further clause in Problem 34. It describes Branson--Gover operators on closed differential forms.

The word “other” means objects besides critical \(Q\)-curvature, whose density form already satisfies (43) with the critical GJMS operator.

06589 | AIM-GEOMETRY-0335

Affine phase retrieval and a same-matroid obstruction

P / partially_solved | AIM 研讨会问题汇编

- what the fibers are of $\operatorname{Log}:M\to\mathcal A$, where $M=V\cap(\mathbb C^*)^n$ and $\mathcal A=\operatorname{Log}(M)$; - when this map is a homeomorphism; - what can be said about the topology of the amoeba of a linear space; and - how this relates to the description of the tropicalization by the matroid of the associated hyperplane arrangement.

The source then states that for $d=1$, hyperplanes are points in a complex line: three points not lying on one real line make Log injective, while if all points lie on one real line, the fibers are the $\mathbb Z_2$-orbits of reflection in that line. It also gives an injective $3d$-hyperplane product construction in $\mathbb C^d$.

The notation recovered from the AIM source is $$ \mathbb C^n,\qquad (\mathbb C^*)^n,\qquad \mathbb Z_2,\qquad V=\mathbb C^d, $$ with four separate questions A--D.

There is a substantive convention issue. If “linear subspace” literally means a vector subspace $V\subset\mathbb C^n$ through the origin, the restricted coordinate hyperplanes form a central arrangement. For $d=1$ they all meet at the origin, rather than forming arbitrary points. Moreover, $$ \operatorname{Log}(e^{i\theta}v)=\operatorname{Log}(v), $$ so Log can never be injective on a nonempty homogeneous $V\cap(\mathbb C^*)^n$. The one-dimensional discussion therefore forces the intended convention to be either:

1. an **affine** d-plane, parameterized by affine forms $$ \Phi:\mathbb C^d\longrightarrow\mathbb C^n,\qquad z\longmapsto(\ell_1(z),\ldots,\ell_n(z)), $$ with $\ell_j(z)=c_j^*\widetilde z$ and $\widetilde z=(z,1)$; or 2. a projective hyperplane complement together with a choice of affine gauge.

This report adopts the first convention. Then $$ M=\mathbb C^d\setminus\bigcup_{j=1}^nH_j,\qquad H_j=\{\ell_j=0\}, \quad \operatorname{Log}_{\mathcal H}(z) =\bigl(\log|\ell_1(z)|,\ldots,\log|\ell_n(z)|\bigr). $$ The associated matroid used below is the matroid of the homogenized forms $\ell_j^h(z,t)$ on $\mathbb C^{d+1}$. This makes the affine/projective convention explicit rather than silently changing the source.

06590 | AIM-GEOMETRY-0277

Affine rigidity and a mobility-two reduction on the Lorentz 3-sphere

P / partially_solved | AIM 研讨会问题汇编

Question 12.0.6. Can a 3-dimensional sphere admit two nonproportional projectively equivalent metrics of indefinite signature?

The text beginning “Acknowledgements” immediately after the question is end matter, not part of the mathematical statement, and is excluded.

In dimension three, an indefinite metric has Lorentz signature, either \((2,1)\) or \((1,2)\) according to convention. The natural literal reading is that both metrics are indefinite. Projective equivalence itself does not require equal signatures; indeed metrics in one projective class can have different signatures. In odd dimension, multiplying one metric by \(-1\) exchanges \((2,1)\) and \((1,2)\) without changing its Levi-Civita connection, so the ordering convention causes no substantive distinction here.

来源字段：https://aimath.org/pastworkshops/geodesicsproblems.pdf

06591 | AIM-GEOMETRY-0353

Affine tractor factories and Q-like tensor-densities

P / partially_solved | AIM 研讨会问题汇编

Problem 2. Construct other natural tensor-densities which transform according to (34). (Any solution yields a conformally invariant natural operator \(L\).)

“It is clear that solutions to Problem 2 have a role to play in the problem of characterising the \(Q\)-curvature and the GJMS operators.”

Immediately before the problem, the notes define a natural tensor-density \(N_g\) to have a linear conformal change law when

\[N_{\widehat g}=N_g+L_g\omega, \qquad \widehat g=e^{2\omega}g. \tag{34} \]

The problem is therefore:

The printed text says “(43),” but the immediately preceding displayed formula is numbered (34), and equation (43) occurs only later in a compiled list. Thus “(43)” is an internal cross-reference typo. The duplicate phrase “of the the form” is also in the PDF. Finally,

\[\iota(D)|C|^2I_g=4\Delta |C|^2 \]

The missing end of the record is:

The preceding notation uses the standard tractor bundle \(\mathcal T\), density bundles \(\mathcal E[w]\), the scale-dependent tractor \(I_g\in\mathcal T[-1]\), and the tractor \(D\)-operator. The key identity is

\[I_{e^{2\omega}g}=I_g+D\omega. \tag{33} \]

If \(a_g\) is the ordinary scalar representative of \(A_g\in\mathcal E[-n]\), then

\[e^{n\omega}a_{\widehat g}=a_g+L_g\omega. \]

This factor is essential in coordinate checks.

Alternative weave tori and the cup obstruction

P / partially_solved | AIM 研讨会问题汇编

What can we say if X is the cluster variety of a (-1)-closure, but T comes from some weave other than the obvious/natural one?

The exact AIM record asks:

This is Problem 2.4 in the workshop section “Stratifications of braid varieties.” The preceding item asks about the geometry of $X\setminus T$ for a general cluster variety and cluster torus. Thus the intended question appears to be: for the cluster/augmentation variety attached to the Legendrian (-1)-closure of a positive braid, what is the status and complement of the torus furnished by a non-natural weave?

The words “weave” and “comes from” need a modern distinction that was not explicit in the AIM sentence:

1. For a positive braid word β with Demazure product w_0, a **Demazure weave** $W:\beta\to\Delta$ uses braid moves, commuting moves, and folds $\sigma_i^2\to\sigma_i$, but no cups or caps. It determines a full-dimensional open torus $T_W\subset X(\beta)$. 2. A **simplifying weave** may also use cups $\sigma_i^2\to 1$ (but no caps). Its algebraic correspondence gives a locally closed piece $S_W\cong\mathbb A^c\times(\mathbb G_m)^t$, where c and t are the numbers of cups and trivalent vertices. This piece is generally not a torus and need not be open. 3. A Legendrian weave or filling can also give a local-system torus in an augmentation variety. The assertion that every such torus is a cluster seed torus is stronger than the theorem for Demazure weave tori and is not established by the papers checked.

In type A, with the usual marking convention, the relevant modern identification is \[X(\beta)\cong \operatorname{Aug}(\Lambda(\beta\Delta)), \] where $\Lambda(\beta\Delta)$ is the Legendrian (-1)-closure. The precise placement of Δ varies among sources; all results below are stated on the braid-variety side, where the conventions are unambiguous.

An exact quantitative shadow-system model

P / partially_solved | AIM 研讨会问题汇编

2. (S. Reisner) Quantify the shadow movement theorem (see [MR]).

22. (S. Reisner) Quantify the shadow movement theorem (see [MR]).

Here [MR] is Meyer and Reisner, *Shadow systems and volumes of polar convex bodies*. Their Theorem 1 is the precise qualitative theorem meant by the AIM question: if `(K_t)_{t in I}` is a nondegenerate shadow system, then

\[F(t):=|K_t^*|^{-1} \]

is convex. The star denotes polarity about the Santaló point, not polarity about a fixed origin in general. The AIM phrase "shadow movement theorem" is informal; it is not the title of a theorem in [MR].

This report interprets "quantify" as asking for a positive lower bound on a Jensen deficit, after normalizing the shadow speed and removing the affine equality directions. It gives an exact nontrivial model calculation and explains why those qualifications are unavoidable. It does **not** claim a general quantitative Meyer--Reisner theorem.

06613 | AIM-CONVEX_GEOMETRY-0025

An explicit iid-uniform counterexample to scalar entropy-power supermodularity

S / solved | AIM 研讨会问题汇编

The AIM list records Problem 6, attributed to Mokshay Madiman. In the source's notation, \(H\) is differential entropy and the variables are independent, real-valued random variables with densities. The question is whether

\[e^{2H(X_1+X_2+X_3)}+e^{2H(X_2)} \mathrel{\geq?} e^{2H(X_1+X_2)}+e^{2H(X_2+X_3)}. \tag{1} \]

The typography and exponent in the AIM PDF are exactly \(H\) and \(e^{2H}\); there is no missing dimension factor because the variables in (1) are scalar. Below, \(h\) denotes the same differential entropy and

\[N(Y):=e^{2h(Y)}. \tag{2} \]

The source remarks that equality holds for Gaussian variables and proposes a related inequality for subset sums \(X_S=\sum_{i\in S}X_i\). It calls the weights in that remark a fractional *covering*. Section 7 below explains a necessary correction: the published entropy-power theorem uses a fractional partition (and consequently also gives the weaker assertion for a fractional packing), whereas unrestricted covering weights cannot satisfy the stated lower bound.

An extended Poncelet problem II

O / open | AMR 问题清单汇编

Let $\gamma=\{x^2+y^2-1=0\}$ and $\Gamma_\varepsilon=\{p_2(x,y)+\varepsilon p_m(x,y)=0\}$, where Γ_0 is an ellipse surrounding γ, the curve $p_2+\varepsilon p_m=0$ is irreducible, $\deg p_m=m\geq3$, and ε is small. Is the Poncelet map for the two ovals conjugate to a rotation if and only if $\varepsilon=0$?

An orbit-category and Rees-deformation model for Legendrians in open books

P / partially_solved | AIM 研讨会问题汇编

Auroux asked whether there is a category for Legendrians in open books, analogous to the Fukaya category of Lagrangians in a symplectic manifold. Morphisms between two Legendrians cannot in general be isolated from their self-chords, so coefficients in the contact homology of the individual Legendrians may be needed. The open-book angular direction suggests a filtration by the rotation of Reeb chords. If two Legendrians lie on one page, their contact-homological morphisms should involve all iterated monodromy images rather than only their ordinary Lagrangian Floer homology. Restoring the binding might be a deformation of an \(A_\infty\)-category. Relative contact homology should also be a module over absolute contact homology. Eliashberg suggested studying the gluing by rounding the convex, flat, and concave boundary pieces in the symplectization of the binding complement and then partially gluing along the resulting convex boundary.

Arbitrary-genus realization and a topology-curvature tradeoff

P / partially_solved | AIM 研讨会问题汇编

Existence of high genus free boundary minimal surface in B^3.

The exact AIM record (Geometry, “Geometric flows and Riemannian geometry,” section “Eigenvalue Estimates,” Problem 5.2) is:

I use the standard strong reading:

* $B^3=\{x\in\mathbb R^3:|x|\leq 1\}$ is the closed unit ball; * $\Sigma\subset B^3$ is a smooth, compact, connected, orientable, properly embedded surface, so $\Sigma\cap\partial B^3=\partial\Sigma$; * its mean curvature vanishes, and it meets $S^2=\partial B^3$ orthogonally (the free-boundary condition); * “genus” is orientable genus, and “high genus” can mean either genera tending to infinity, every sufficiently large genus, or the strongest version, every prescribed genus; * unless stated otherwise, the number b of connected components of $\partial\Sigma$ is not prescribed.

The source does not say “embedded,” “orientable,” or “connected boundary.” Modern results solve the question with all of those additional properties: one may prescribe every genus, and even every positive number of boundary components. Nothing below silently changes the source; these are explicit strengthened readings. Nonorientable crosscap genus is a different realization problem and is not asserted here.

06637 | AIM-GEOMETRY-0008

Attainment and a quantitative segment bound for planar p-capacity

P / partially_solved | AIM 研讨会问题汇编

The source asks the following. For \(1<p<2\) and a bounded convex set \(K\subset\mathbb R^2\), define the homogeneous variational capacity \[\operatorname{Cap}_p(K)=\inf\left\{ \int_{\mathbb R^2}|\nabla u|^p\,dx: u\in C_c^1(\mathbb R^2),\quad u\geq1 \text{ on a neighbourhood of }K\right\}. \] Among convex sets of prescribed perimeter, is this capacity minimized by a segment, with a segment's perimeter counted twice?

There is one necessary correction to the source text. At \(p=2\) the displayed infimum is mathematically well-defined, but it is degenerate: it equals zero for every compact planar set. Indeed, if \(K\subset B_R\), logarithmic radial cutoffs supported in \(B_A\) have energy tending to \(2\pi/\log(A/R)\to0\). Logarithmic capacity is the nondegenerate replacement.

To include flat limits without ambiguity, throughout this report the perimeter of every nonempty compact convex set is \[P(K):=\int_0^\pi w_K(\theta)\,d\theta, \qquad w_K(\theta)=h_K(e_\theta)+h_K(-e_\theta). \] This is the usual boundary length when \(K\) has interior, while \(P([a,b])=2|a-b|\). It is translation invariant, homogeneous, Minkowski additive, and continuous for Hausdorff convergence.

来源字段：http://aimpl.org/symmetrybreaking/2/

06638 | AIM-GEOMETRY-0007

Attainment and normalization transfer for Steklov polygons

P / partially_solved | AIM 研讨会问题汇编

Given an integer \(n\ge 3\), what is the maximal first positive Steklov eigenvalue \(\sigma_1\) among \(n\)-sided polygonal sets of fixed area, or of fixed perimeter? Even \(n=3,4\) are said to be open, and corners must be treated carefully in a shape derivative.

The exact AIM record, attributed there to Iosif Polterovich, asks:

It leaves several mathematically consequential choices unstated:

- Is a polygon required to be simple, convex, or merely connected? - Does “\(N\)-gon” mean exactly \(N\) genuine corners, at most \(N\) sides, or \(N\) labelled vertices with collinear/repeated labels allowed? - Are holes, self-intersections, disconnected unions, or zero-area degeneracies allowed, and if so how are their sides and boundary lengths counted? - Is the perimeter the total length of every boundary component?

For status statements about the customary conjecture, this report reads an \(N\)-gon as a bounded simply connected Lipschitz domain whose boundary is a simple polygonal Jordan curve. The proved existence theorem uses the more precise closed class \(\mathcal C_N\) of interiors of compact **convex** polygons with nonempty interior and at most \(N\) maximal sides, modulo rigid motions. Convexity is a substantive restriction: Steklov eigenvalues are not domain-monotone, so one cannot pass to a convex hull without proof.

Using “at most \(N\)” is essential for compactness. If collinear subdivision of an edge is permitted, it is also exactly the geometric closure of the class of labelled \(N\)-gons. If exactly \(N\) noncollinear, distinct vertices are required, the admissible class is not closed and the existence conclusion below need not follow.

P / partially_solved | Oberwolfach 报告问题汇编

For integers $d\geq1$ and $r\geq2$, determine the least n such that every affine map f from the simplex Δ^{n-1} to $\mathbb{R}^{d}$, with its vertices partitioned into $d+1$ color classes each of size at least r, admits r pairwise disjoint rainbow faces whose images have a common point; is the Bárány-Larman conjecture $n(d,r)=(d+1)r$ true? In the alternative colored Tverberg problem, determine the least t such that the analogous assertion holds for equal color classes of size t, equivalently, whether $t(d,r)=r$.

Billiards and Quantitative Symplectic Geometry - Alfonso Sorrentino - Problem 1

O / open | AMR 问题清单汇编

Problem: *Provide examples of real-world systems (from physics, mechanics, biology, economics, etc\ldots) that can be modeled as locally conformal symplectic flows or maps.*

In the following, we provide some material that could be useful to address this question. We begin by recalling the formal setting, starting from the well-understood *global* conformally symplectic case, namely when the ambient manifold is a symplectic manifold. We then introduce the *local* conformally symplectic case and provide some remarks and computations that may be useful for identifying and constructing the sought-after examples.

Billiards and Quantitative Symplectic Geometry - Bernhard Albach, Umberto Hryniewicz, and Alexandru Oancea - Problem 1

O / open | AMR 问题清单汇编

Conjecture 1. For a Reeb flow on a closed connected 3-manifold, either there are exactly two periodic orbits, or $$ \liminf_{T\to+\infty} \frac{\log P(T)}{\log T} \geq 2 $$ holds.

The conjecture above, which is also cited in [DanCG], has been confirmed in [Albach] for geodesic flows of reversible Finsler metrics on S^2. This significantly improves the best known growth rate $$ \liminf_{T\to+\infty} P(T)\frac{\log T}{T} > 0 $$ which was due to Hingston [Hingston1993]. In fact, in this case there is always quadratic growth since the number of closed geodesics is always infinite. On closed connected orientable reversible Finsler surfaces of genus ≥ 1, Conjecture 1 is long known to be true for the geodesic flow. Hence, there is always quadratic growth of closed geodesics in any reversible Finsler closed surface -- orientable or not. Geodesic flows on S^2 can be lifted to Reeb flows on the standard contact 3-sphere. It should be noted that the results from [Albach] cover a significantly larger class of such Reeb flows.

One might wonder if the same holds for a general low-dimensional symplectic dynamical system, which means either a symplectic diffeomorphism on a compact symplectic surface (with or without boundary), or the Hamiltonian flow on a 3-dimensional compact regular energy level without boundary. In [Albach] it is also proved, via a simple argument based on the transverse foliations by Le Calvez and Tal [LeCalvez-Tal], that the same dichotomy as in Conjecture 1 holds for any symplectic diffeomorphism on S^2.

The confirmation of Conjecture 1 is, however, **not** the problem proposed here. Instead, we would like to propose the problem of investigating whether the same phenomenon holds in any dimension.

06679 | AMR-129-0026

Billiards and Quantitative Symplectic Geometry - Bernhard Albach, Umberto Hryniewicz, and Alexandru Oancea - Problem 4

O / open | AMR 问题清单汇编

Problem 3. Is it true that for a Hamiltonian diffeomorphism on $\mathbf{C}P^n$ with infinitely many periodic orbits the inequality $\liminf_{T\to+\infty} \frac{\log P(T)}{\log T} \geq 2$ holds?

In low-dimensions, integrable Hamiltonian systems indicate that quadratic growth should be sharp. To justify this, if one would count invariant tori foliated by periodic orbits or isolated closed geodesics on a closed Riemannian 2-sphere of revolution, instead of only closed geodesics, then it is simple to present examples where the growth is exactly quadratic. One would conjecture that it is possible to perturb such a system to get existence of systems with exact quadratic growth of periodic orbits. The corresponding statement is also expected to be true for integrable annulus maps, as pointed out by Gerhard Knieper. The construction of such a perturbation is not trivial and can potentially be a very difficult task.

The question that we are asking in higher dimensions is to be understood in the context of the question asked by Hofer and Zehnder in [HZ, p. 263], whether every Hamiltonian map on a compact symplectic manifold (M,ω) possessing more fixed points than necessarily required by the Arnold conjecture possesses always infinitely many periodic orbits. This question came to be known as the Hofer-Zehnder conjecture.

Shelukhin proved this conjecture in [Shelukhin] for closed monotone symplectic manifolds with semi-simple even-dimensional quantum homology ring, a class that includes complex projective spaces. His proof provides the estimate $\liminf_{T\to+\infty} P(T) \frac{\log T}{T}>0$, i.e., the growth rate of the number of periodic points is at least the growth rate of the prime numbers, just like in [Hingston1993].

Ginzburg and G\"urel interpreted more broadly the question of Hofer and Zehnder, in the sense that the existence of a fixed point not strictly required by Floer theory forces the existence of infinitely many periodic points, for example the existence of a hyperbolic fixed point [Ginzburg-Gurel2014], or the existence of a non-contractible fixed point [Gurel2013,Ginzburg-Gurel2016]. Notably, the estimate $\liminf_{T\to+\infty} P(T) \frac{\log T}{T}>0$ is already proved by G\"urel in [Gurel2013]. One could venture to ask whether quadratic growth holds in such cases as well.

Billiards and Quantitative Symplectic Geometry - Boris Khesin - Problem 1

O / open | AMR 问题清单汇编

1. Find physically interesting examples of infinite-dimensional billiards

Motivation: It is a well-known folklore (made into a theorem under certain conditions) that billiard and geodesic flows are closely related by taking appropriate limits, see e.g. [Giannetto, Lange]. There are various physical problems leading to the construction of geodesics on infinite-dimensional spaces. One of the sources is the Euler-Arnold equation describing geodesics on infinite-dimensional groups. In particular, solutions of the Euler equation of incompressible hydrodynamics can be regarded as geodesics on the group of volume-preserving diffeomorphisms with respect to the right-invariant L^2-metric on the group. A similar framework exists for the KdV equation, magnetohydrodynamics, Heisenberg chain, etc. [Arnold66, ArnKh] A natural question is whether there exist interesting infinite-dimensional billiards, possibly related to equations of mathematical physics.

One possible approach would be to consider not one or several particles hitting a wall with a billiard reflection, but a continuum of particles doing that. The difficulty is that then the reflected flow will be passing through the same domain as the flow before reflection, and hence there will be two different flows passing simultaneously through each point in the vicinity of the boundary. However, this is exactly the setting handled by multi-phase flows and by the corresponding groupoid structure for generalized flows, see [Brenier, IzKh]. This way infinite-dimensional billiards in fluids might correspond to a choice of appropriate boundary conditions in the diffeomorphism groupoid for two-phase fluids. It would be very interesting to develop the corresponding theory for multi-phase fluids with billiard reflections from the boundary.

Billiards and Quantitative Symplectic Geometry - Boris Khesin - Problem 2

O / open | AMR 问题清单汇编

3. Is there a fluid of negative density?

Motivation: A mild reformulation of the question above is as follows: *Study continuous versions for the interactions of particles of positive and negative mass. Explore the relation with pseudo-Euclidean metrics.*

To motivate this question, we start with the motion of three point-like beads of masses m_1, m_2, and m_3 on a frictionless ring, making elastic collisions with each other. By using the momentum and energy conservation laws and quotienting out the rotational symmetry, the motion of the beads is equivalent to a billiard trajectory in an acute triangle with angles given by $$ \tan \alpha_1=\sqrt{\frac{m_1(m_1+m_2+m_3)}{m_2 m_3}}, $$ as well as respective cyclic permutations of indices. (Note that if one of the masses, say m_3, goes to infinity, this corresponds to a billiard in a right triangle, $\alpha_3=\pi/2$, which is equivalent to two beads constrained to a segment between two walls.) This equivalence allows one to answer various questions on the existence of periodic orbits, etc.

A natural question: ``Does there exist a mechanical system corresponding to a billiard in an obtuse triangle?'' has a curious answer. This would be a system where one allows beads of *negative mass*, as long as they satisfy $(m_1 + m_2 + m_3)m_1 m_2 m_3 > 0$, see [GlashowMittag]. Thus, if the masses have the same sign, then the associated triangle is acute; otherwise, it is obtuse. In this way, the obtuse triangular billiard tables suggest considering the one-dimensional dynamics of particles with positive and negative mass. For instance, in a nice paper [Artigue], Artigue presents a study of all possible cases of positive and negative masses. One introduces a small particle of negative mass, ``graviton'', which via elastic collisions, pulls together other positive masses (and might be the source of gravity in general!), cf. [Wiki].

However, there is a different point of view: instead of changing the angles, one can consider the billiard in a fixed triangle on the plane with an appropriately rescaled Euclidean metric. In the case of negative mass(es), the metric becomes pseudo-Euclidean. Billiards in pseudo-Euclidean (or, more generally, in pseudo-Riemannian) metrics were described in [KhTab]. The corresponding theory and applications to gravitons are described in [Artigue]. The problem is to construct a continuous version of this theory of particles of negative mass. Are there some interesting phenomena related to the corresponding Euler-like equations for the ``fluid of negative density''?

Acknowledgments. BK thanks the organizers and participants of the workshop on *Billiards and Quantitative Symplectic Geometry* at the Heidelberg University for a stimulating atmosphere. The research was partially supported by an NSERC Discovery Grant.

Billiards and Quantitative Symplectic Geometry - Jean-Fran\c{c - Problem 1

O / open | AMR 问题清单汇编

Problem statement Let M be a closed manifold that is not a $K(\pi,1)$, and endow the cotangent bundle T^*M with its standard symplectic form. We conjecture that, for any closed and connected hypersurface $\Sigma\subset T^*M$ and any Hamiltonian $H:T^*M\to\mathbf{R}$ that admits Σ as a regular energy level $\Sigma=H^{-1}(c)$, there exists $\varepsilon>0$ such that almost all energy levels of H in the interval $(c-\varepsilon,c+\varepsilon)$ carry a contractible periodic orbit of H.

Context and motivation.

The study of closed characteristics on hypersurfaces of symplectic manifolds is a fundamental topic in symplectic geometry. When such a closed hypersurface is of contact type, the famous Weinstein conjecture [Weinstein79], first proved by Viterbo in $\mathbf{R}^{2n}$ [Viterbo-WeinsteinR2n], claims the existence of at least one closed characteristic. Without assuming the contact type hypothesis, given some symplectic manifold (W,ω) and some proper autonomous smooth Hamiltonian $H:W\to \mathbf{R}$, one can ask which regular levels $H^{-1}(c)$ contain at least one closed characteristic. The question of whether *all* the regular levels of any Hamiltonian satisfy this property is known as the Hamiltonian Seifert conjecture. It was disproved already for $W=\mathbf{R}^{2n}$ by Ginzburg [Ginzburg-Ham-Seifert1] [Ginzburg-Ham-Seifert2] and Herman [Herman] for $2n\geq6$; G\"urel and Ginzburg later provided a ${\mathcal{C}^2$ counterexample for $2n=4$ [Ginzburg-Gurel1], [Ginzburg-Gurel2]. Once the conjecture had been disproved, it is natural to ask whether at least some of the regular levels $H^{-1}(c)$ contain closed characteristics. In the particular case $W=\mathbf{R}^{2n}$ endowed with the standard symplectic form it actually turns out that many of them do. More precisely, a celebrated result of Hofer-Zehnder [HZ] and Struwe [Struwe] asserts that almost all (regular) levels of a smooth proper Hamiltonian $H:\mathbf{R}^{2n}\to \mathbf{R}$ carry at least one closed characteristic. This result is known as *the almost existence property*.

In a cotangent bundle any closed and connected hypersurface separates T^*M into a bounded component and an unbounded component. Hofer and Viterbo [HV88] proved that the above property holds for all hypersurfaces that enclose the 0-section, without contractibility. Albers-Frauenfelder-Oancea [AFO17] proved the above property under the assumption that the Hurewicz map $\pi_2(M)\to H_2(M)$ does not vanish. Their proof uses the multiplicative structure on symplectic homology twisted by suitable rank 1 local coefficients. Frauenfelder-Pajitnov [Frauenfelder-Pajitnov] proved this property for rationally inessential manifolds M, i.e., manifolds whose fundamental class with rational coefficients vanishes under their classifying map to $B\pi_1$. Their proof involves S^1-equivariant homology and localization.

Remarks, partial results

In our recent paper [BDHO-cotangent] we have proved this property for any M that is not a $K(\pi,1)$, but for a somewhat restricted class of hypersurfaces Σ. Our proof uses a new version of symplectic homology with differential graded local coefficients.

Our hope is that the methods of [AFO17, Frauenfelder-Pajitnov, BDHO-cotangent], which are complementary to each other, can be combined in order to prove the above conjecture.

In all cases in which it is known to hold for all closed hypersurfaces, the contractible almost-existence property is a consequence of the finiteness of the so-called *π_1-sensitive Hofer-Zehnder capacity* for the disc cotangent bundle D^*Q. One could also conjecture that this capacity is finite for all manifolds Q that are not $K(\pi,1)$.

The assumption of not being $K(\pi,1)$ seems reasonable as a borderline between existence and non-existence of contractible periodic Hamiltonian orbits: the standard class of manifolds that *are* $K(\pi,1)$ is that of manifolds that carry a Riemannian metric of non-positive sectional curvature, and such metrics do not admit contractible closed geodesics. In particular, none of the positive radius sphere bundles for such a Riemannian metric carries any contractible closed characteristic. Thus, in the above conjecture, the contractibility requirement is intimately tied to the non-$K(\pi,1)$ assumption.\\

06683 | AMR-129-0005

Billiards and Quantitative Symplectic Geometry - Johanna Bimmermann - Problem 1

O / open | AMR 问题清单汇编

Question:. \begin{center} Let (N,g) be an orientable closed hyperbolic surface.\\ Does $c_{\mathrm{HZ}}\bigl(D^{*}N,d\lambda\bigr)<\infty$ hold? \end{center}

We included the word ``orientable'' for the following reason. If the Euler characteristic $\chi(N)$ is divisible by 4 and N is non-orientable, then there exists a Lagrangian embedding $N\hookrightarrow (\mathbb{C}^{2},\omega_{0})$ [Giv86]. By Weinstein's tubular neighborhood theorem this implies that, for some $\varepsilon>0$, $(D^{*}_{\varepsilon}N,d\lambda)\hookrightarrow (\mathbb{C}^{2},\omega_{0})$ embeds symplectically, which implies finiteness.\\

We now present two arguments that might hint finiteness and two arguments that might hint infiniteness. These are not mathematically worked out and are based on discussions with Gabriele Benedetti, Dylan Cant, Stefan Nemirovski and Alexandru Oancea.

Finiteness.

- *Capacity relative to the zero section is finite.*

There is a modification of the definition of c_{HZ} for which the answer to (Q) is yes. Require the Hamiltonians $H\in C_c^\infty(D^{*}N,\mathbb{R}_{\ge 0})$ to attain their maximum along the zero section $N\subset D^{*}N$, i.e.,\ $H|_{N}=const.=\max H$. It is a direct consequence of [Wbr06] that $$ c_{\mathrm{HZ}}(D^{*}N,N,d\lambda)=\operatorname{sys}<\infty, $$ where sys denotes the length of the shortest closed (non-contractible) geodesic.

- *Displaceability of the zero section after removing a point.*

Displacement energy gives an upper bound for the Hofer--Zehnder capacity, and if the zero section would be displaceable then so is $D^{*}_{\varepsilon}N$ for ε small. In particular, displaceability of the zero section yields finiteness of $c_{\mathrm{HZ}}(D^{*}N,d\lambda)$. Actually, the full zero-section $N\subset T^{*}N$ of a closed manifold N is never displaceable, but it becomes displaceable if one removes an arbitrarily small disc $D_{\varepsilon}\subset N$.

To see this, take a Morse function $f:N\to\mathbb{R}$ with all critical points in $D_{\varepsilon/2}$. Then there exists some $\delta>0$ such that $\vert \nabla f\vert \geq \delta$ on $N\setminus D_{\varepsilon}$. Hence, the Hamiltonian flow of $H(q,p)=\frac{1}{2}\vert p\vert^2+f(q)$ displaces $N\setminus D_{\varepsilon}\subset T^{*}N$. We obtain: $$ c_{HZ}(D^*(N\setminus D_\varepsilon), d\lambda)<\infty,\quad \forall\varepsilon>0. $$

Infiniteness.

- \emph{Lack of pseudoholomorphic curves in $T^{*}N$.}

Most known bounds for the Hofer--Zehnder capacity ultimately come from pseudoholomorphic curves, as first explained by Hofer--Viterbo [HV92]. Indeed one needs a form of uniruledness, morally, a pseudoholomorphic curve through every point. For all closed surfaces N for which finiteness of $c_{\mathrm{HZ}}(D^{*}N,d\lambda)$ is known, uniruledness is ensured by the existence of a Lagrangian embedding $N\hookrightarrow \Sigma$ into a ruled complex surface Σ; for example $$ S^{2}\subset \mathbb{CP}^{1}\times\mathbb{CP}^{1},\qquad \mathbb{RP}^{2}\subset \mathbb{CP}^{2},\qquad T^{2}\subset \mathbb{CP}^{2},\ \ldots $$ For orientable hyperbolic surfaces, however, no such embedding exists. Indeed, suppose that an orientable surface N of genus $g\ge 2$ was embedded as a Lagrangian into a ruled complex surface Σ. Then the self-intersection satisfies $$ [N]^{2} \;=\; -\chi(N) \;=\; 2g-2 \;>\; 0, $$ since for a Lagrangian surface L in a complex surface one has $[L]^{2}=-\chi(L)$. On the other hand, if $[\omega]$ denotes the Kähler class of Σ, the Lagrangian condition $\omega|_{N}=0$ implies $$ [\omega]\cdot \mathrm{PD}[N] \;=\; 0. $$ Thus $[\omega]$ and $\mathrm{PD}[N]$ are orthogonal classes of positive square in $H^{2}(\Sigma;\mathbb{R})$, which is impossible as the intersection form has exactly one positive eigenvalue [Bea96, Prop.\ III.18]. Consequently, an orientable hyperbolic surface cannot embed as a Lagrangian into a ruled complex surface.

- *No upper bounds from symplectic homology.* The other existing strategies for proving finiteness of the Hofer--Zehnder capacity (or uniruledness) of cotangent bundles rely on symplectic homology. In particular, the existence of a *dilation class* $\Delta x = 1$ [BC25], a nontrivial *pair-of-pants product* $x \star y = 1$ [Iri14], or the vanishing of symplectic homology with (differential graded) local coefficients [AFO17,BDHO-cotangent] implies such finiteness. Except for Irie's pair-of-pants product, all these criteria provide upper bounds for the π_1-sensitive Hofer--Zehnder capacity, which only requires all contractible orbits to be slow. It is easily seen that for a hyperbolic surface, $c_{HZ}^0(D^*N, d\lambda)=\infty$. For example, the geodesic flow, generated by the Hamiltonian $E(q,p)=\tfrac{1}{2}\lvert p\rvert_q^2$, has no contractible periodic orbits. Hence, none of these criteria can be used to prove finiteness for hyperbolic surfaces.\\

For cotangent bundles there is a ring isomorphism between symplectic homology and the homology of the free loop space [Abo15]. For a closed hyperbolic surface N, the latter can be computed explicitly since N is a $K(\pi,1)$ [LO15, Ch.\ 1.4]: $$ H_*(\mathcal{L}N,\mathbb{Z}) \cong \bigoplus_{[g]\in \mathrm{Conj}} H_*(K(C_\pi(g),1),\mathbb{Z}), $$ where $C_\pi(g)$ denotes the centralizer of $g\in\pi=\pi_1(N)$. Here $C_\pi(e)=\pi$ and $C_\pi(g)\cong\mathbb{Z}$ for $g\neq e$, giving $$ H_*(\mathcal{L}N,\mathbb{Z}) \cong H_*(N,\mathbb{Z}) \oplus \bigoplus_{[g]\neq[e]} H_*(S^1,\mathbb{Z}). $$ This simple structure immediately rules out the existence of a nontrivial loop product $x\star y = 1$, as $\star: H_i(\mathcal{L}N,\mathbb{Z})\times H_j(\mathcal{L}N,\mathbb{Z})\to H_{i+j-2}(\mathcal{L}N,d\lambda)$, and the unit is the only degree 2 element.

We conclude with a possible strategy to prove infiniteness by linking quantitative symplectic geometry with billiards.

Lower bounds via hyperbolic billiards. If $\Omega\subset N$ is open and simply connected, it lifts to an open subset of the hyperbolic plane $\mathbb{H}^{2}$ with compact closure, let $\Omega\text{-}\mathrm{sys}$ denote the length of the shortest billiard trajectory in Ω. Then $$ \Omega\text{-}\mathrm{sys}\le c_{\mathrm{HZ}}(D^{*}N,d\lambda). $$ Note that the notion of “billiard trajectory’’ here might be slightly relaxed: the lower bound only requires closed billiard trajectories to have length $\ge \Omega\text{-}\mathrm{sys}$ when they arise as limits of approximate solutions in the sense of approximation schemes developed in [AM11,Voc21].

Magnetic billiards for strong magnetic fields..

Magnetic billiards were introduced and studied in [berry-robnik]. In this model, the billiard ball moves under the influence of a constant magnetic field along Larmor circles (for a magnetic field of magnitude B, the Larmor circles have radius $1/B$). The only known example of an integrable magnetic billiard is a circular billiard. An algebraic approach to this problem was discussed in [magnetic1], [magnetic2]. Numerical experiments were performed in [albers]. Moreover, the approach of total integrability works well for convex magnetic billiard in a *weak* constant magnetic field [bialy-magnetic-hopf].

Question 1. {\it Is it true that the only totally integrable magnetic billiard in a *strong* constant magnetic field is necessarily circular?}

Minkowski billiard..

The model of Minkowski and, more generally, Finsler billiards, was introduced and studied by Gutkin and Tabachnikov in [GUTKIN2002277]. It plays an important role in a recent study by Artstein-Avidan, Karasev, and Ostrover [Artstein_Avidan_2014] on Mahler's conjecture. Consider a smooth convex curve $\gamma\subset \mathbb{R}^2$, and a Minkowski (not necessarily symmetric) norm N. The Minkowski billiard in γ with respect to the norm N is defined as a twist map that corresponds to the generating function \[L(s_0,s_1)=N(\gamma(s_1)-\gamma(s_0)) ,\] and the corresponding variational principle $ \mathcal{L}\{s_n\}=\sum_{n} L(s_n,s_{n+1}),\ $ where γ is parametrized by N-arc length parameter (meaning, $N(\dot{\gamma}(s))=1$). Thus, the Birkhoff billiard is a special case of the Minkowski billiard when N is chosen to be a Euclidean norm.

Question 2. (Communicated by Yaron Ostrover) *Suppose that the Minkowski billiard, corresponding to the norm N, in a unit ball of N is totally integrable. Does this imply that the norm N is necessarily Euclidean?*

This question was answered affirmatively in [IMRN] for billiard tables with a finite symmetry group.

Newton equations with $1\frac 12$ degrees of freedom, with periodic potential..

Newton's equation $\ddot u=-V'_u(u,t)$ is the Euler-Lagrange equation associated with the Lagrangian $L(u,\dot u, t)=\frac 12\dot u^2-V(u,t)$. Assume that V is periodic both in u and in t. The corresponding Hamiltonian flow acts on $T^*\mathbb{S}^1\times\mathbb{S}^1$. One can prove that this flow is totally integrable on the whole phase space if and only if V does not depend on u. Moreover, if $V=V(nu+mt)$, with $ m\neq0, n\in\mathbb{Z}$, then there exists an integral of motion that is quadratic in momentum p, and hence the system is totally integrable in a neighborhood of infinity, $|p|>c$, for sufficiently large c.

Question 3. *Are there other potential functions V such that the system is totally integrable at infinity?*

O / open | AMR 问题清单汇编

An elliptic PDE.

Consider an elliptic PDE $\Delta u=-V'_u(u, x_1, \ldots ,x_n)$, where $\Delta=\sum_{i=1}^{n}\partial^2_{x_i}$ and V is a 1-periodic function of $u, x_1,\ldots ,x_n$. This equation is the Euler-Lagrange equation for the functional $\int \left(\frac 12|\nabla u|^2-V(u, x_1, \ldots, x_n)\right) dx_1 \ldots dx_n$. Aubry-Mather theory, as well as KAM theory for this equation, were developed by J. Moser [moser] and V. Bangert [bangert]. If V does not depend on u, we have the equation $\Delta u=0$. In this case, for any rotation vector $\alpha\in \mathbb{R}^n$, there exists a family of minimal solutions of the form $u=\alpha\cdot x+c$. Thus, for every α, the graphs of these solutions form a foliation of $\mathbb{T}^{n+1}(u,x_1, \ldots, x_n)$ by minimals (hyperplanes of slope α).

Question 4. {\it Let V be a 1-periodic potential. Suppose that for every $\alpha \in \mathbb{R}^n$ there exists a foliation of $\mathbb{T}^{n+1}$ by graphs of minimal solutions of slope α. Is it true that, in this case, V does not depend on u?}

For compactly supported potentials V, a variational version of this question was approached in [bialy-mackay].

Acknowledgments. The research was supported by ISF grant 974/24.

Billiards and Quantitative Symplectic Geometry - Olga Paris-Romaskevich - Problem 1

O / open | AMR 问题清单汇编

Tiling billiards. A tiling billiard is a dynamical system associated with a plane polygonal tiling. Here is the rule: a particle moves in a straight line until it reaches an edge of a polygon; then it crosses into a neighboring polygon with its velocity direction changed according to Snell's law of refraction with refraction coefficient -1. Several families of tiling billiards have been studied since 2015. Here is the full (as far as I know) list of them. For this list, a tiling billiard's name is followed by a description of the underlying tiling, the generic behavior of trajectories, and some bibliography.

1. **Trihexagonal tiling billiard** (a periodic tiling by regular hexagons and triangles) has orbits that are dense in an unbounded periodic open set, as proven in the work of Diana Davis and Pat Hooper [DH18].

2. **Triangle tiling billiards** (a periodic tiling by one triangular tile via central symmetries) have orbits that are typically either periodic or escape linearly to infinity (we call this **integrable behavior**). There exists a zero-measure set of exceptional triangle tilings (parametrized by the Rauzy gasket (The Rauzy gasket has now been extensively studied since it appears as the parameter set of exceptional trajectories in various dynamical and topological settings, see, in particular, [AR91, AHS, DDe]. For a definition of the Rauzy gaskets, an attractor of a multidimensional continued fraction algorithm, and an introduction to their dynamical properties, see [AS].)) that permit trajectories escaping non-linearly (These trajectories necessarily pass by the circumcenters of all tiles that they cross.). This has been shown in a series of works [BDFI18, TAF, H_Paro], see also [highlights_O]. For a quick introduction to the triangle tiling billiards and their properties, I recommend a short animation movie by Ofir David [Ofir], based on the research results in [TAF].

3. **Cyclic quadrilateral tiling billiards** (a periodic tiling by one cyclic quadrilateral via central symmetries) have integrable behavior, see [H_Paro, TAF]. The set of exceptional tilings (admitting non-linearly escaping trajectories) has been recently classified in [Dynnikovetal] and is parametrized by a fractal set named Novikov's gasket.

4. **Double triangle tiling billiards** (a periodic tiling by a pair of triangles Δ and Δ' with one common edge a, and such that their angles α and α' opposite to this edge are equal) are generalizations of triangle tiling billiards. Partial results on the dynamics have been obtained by Magali Jay in her thesis [Jay_thesis]. Probably, their behavior is integrable, as in the two previous examples.

5. **Refractive wind-tree model** (the tiling is defined by rectangles of size $a \times b$ with centers belonging to a lattice Λ, and the complement of their union (an \guillemotleft{} unbounded polygon \guillemotright{})) has its generic trajectories trapped in bands, see [Jay_thesis].

6. **Generalized tiling billiards** are a generalization of a tiling billiard corresponding to one fixed polygon that does not necessarily tile the plane. A trajectory starting in a copy of P can still be followed by reflecting P by central symmetry with respect to the midpoint of a crossed side, thus producing a local refraction of a trajectory with coefficient -1. **Cyclic pentagonal generalized tiling billiards** show a behavior different from triangle and cyclic quadrilateral tiling billiards. In particular, the orbits may escape in a non-linear way in open sets: they have a principal direction but deviate from it, see [Jay_pentagons] and [Jay_thesis]. The generic behavior is not yet known.

7. **Brick tiling billiards** (a periodic tiling defined by two rows of 1×1 squares that are shifted relative to one another by some parameter $\theta \in (0,1)$) have all of their orbits periodic when $\theta \in \mathbb{Q}$, as shown in [thesis_park]. The behavior for $\theta \notin \mathbb{Q}$ has not yet been studied.

A tiling of the plane by polygons is **locally foldable** if it is 2-colorable and the **defect of a vertex** (the alternating sum of angles in that vertex) is equal to 0. This property implies (see [TAF]) strong restrictions on the dynamics of the corresponding billiard: all trajectories are either periodic or escaping, and any trajectory passes through each tile at most once. Moreover, the study of the dynamics of tiling billiards in locally foldable tilings can be related to Novikov's problem in topology. See [Dynnikov_main] for an introduction to Novikov's problem and [PaRoH, Dynnikovetal] for its link to tiling billiards. This is the case for examples $2., 3.$, and $4.$ above.

It is worth mentioning that all of the work on tiling billiards mentioned above was accomplished by reducing their dynamics to that of linear flows on certain families of translation or half-translation surfaces, although the construction method is ad hoc for each family.

Billiards and Quantitative Symplectic Geometry - Olga Paris-Romaskevich - Problem 3

O / open | AMR 问题清单汇编

\begin{question} In the class of tiling billiards in periodic tilings, is there a finite list of generic archetypal behaviors? For instance, the tiling billiards for which generic behavior is understood fall into one of two categories: either their typical trajectories are dense in open sets of the plane, as in cases 1. and 5., or the behavior is integrable (typical trajectories are either periodic or linearly escaping), as in cases 2. and 3. (and conjecturally in case 4. as well). One could ask whether such a dichotomy holds in general. \end{question}

Locally foldable periodic tiling billiards, up to some technical regularity conditions, are integrable. This is not at all obvious but follows from fine Morse theory developed by Ivan Dynnikov, see in particular Theorem 1 in [Dynnikov_main], and [PaRoH]. The first ingredient in the proof comes from [BDFI18] and was further developed in [TAF, PaRoH]. It states that for any locally foldable tiling there exists a **global folding map** $\mathcal{F}$ defined on a tiled plane such that, on the restriction of two neighboring tiles, it is a folding of one of them onto the other along the common edge (which is an axial symmetry with respect to this edge).

It seems that the tilings on which one could start testing Question 1 should be the simplest not-locally foldable tilings - for example, irrational brick tiling billiards or the parallelogram tiling billiards that we discuss in Question 2.

Billiards and Quantitative Symplectic Geometry - Serge Tabachnikov - Problem 1

O / open | AMR 问题清单汇编

Projective billiards.. Projective billiards were defined in [Ta97]. A projective billiard table is a convex domain with smooth boundary equipped with a transverse field of directions; the phase space is the same as that of the conventional billiard, and the reflection law is such that the tangential component of the incoming velocity vector is preserved, whereas the transverse component is reversed.

Problem: *when does a projective billiard possess an invariant symplectic form?* And, related, *when does it have a variational description?*

One such situation is described in [Ta97-1]: the billiard table is bounded by a sphere, and the transverse field satisfies a certain *exactness* condition. The invariant symplectic form on oriented lines that intersect the sphere is induced by the hyperbolic metric in its interior (the projective, or Beltrami-Cayley-Klein model). Another example, in dimension 2, is when the billiard curve is an arbitrary oval, but the lines of the transverse field are all concurrent; the invariant area form comes from the standard area form in the plane via polar duality (see [Ta97]).

In recent papers [Glu,GM], a somewhat related question was studied: when is a Minkowski billiard projective? (In which case it has a variational description and an invariant symplectic form). The answer is that such a billiard is the conventional one in some Euclidean metric.

O / open | AMR 问题清单汇编

Inner and outer periodic orbits on immersed submanifolds.. Let M be a closed immersed submanifold of Euclidean space. A generalized n-periodic billiard trajectory is an n-gon inscribed in M (that is, the vertices lie on M) that has an extremal perimeter.

Problem: *estimate from below the number of n-periodic trajectories in terms of the topology of M and the immersion*.

The case of $n=2$ was studied in [Pu], where the answer is given in terms of the topology of M (but not of the immersion). For example, for a 2-dimensional torus, the number of such *diameters* is not less than 10, and this estimate is sharp. For higher periods, see [Du1,Du2].

A similar question can be asked about periodic trajectories of the outer symplectic billiard about M; see [ACT] for their recent study.

Billiards and Quantitative Symplectic Geometry - Serge Tabachnikov - Problem 3

O / open | AMR 问题清单汇编

Complexity of polygonal symplectic billiards.. Symplectic billiards were introduced in [AT]; the polygonal ones were studied in [ABSST,ALW].

Label the sides of a polygon by some symbols and assign to a billiard trajectory its symbolic code, the corresponding bi-infinite word in these symbols. The set of all trajectories yields a collection of such words. The complexity function $p(n)$ is the number of different subwords of length n in this collection.

For the conventional polygonal billiards, it is known that the complexity function is sub-exponential (the literature on this subject is huge, starting with [Ka]), and it has polynomial, actually cubic, growth for rational billiards (whose angles are rational multiples of π). For polygonal outer billiards, the growth of the complexity function is polynomial, see [GT].

Problem: *study the complexity of polygonal symplectic billiards*.

Note that there are examples of such billiards with all trajectories being periodic; in such cases, the complexity function has a zero growth rate.

Ivrii's conjecture for outer symplectic billiards.. The Ivrii conjecture for conventional billiards asserts that the set of periodic orbits has zero measure (with respect to the measure associated with the invariant symplectic structure of the phase space). A similar conjecture applies to the outer symplectic billiards.

For conventional billiards, this conjecture is proved for periods $n=2,3$ in all dimensions, and for $n=4$ in dimension 2. For planar outer billiards, there are proofs for $2n+1$-periodic orbits with rotation number n and for $2n$-periodic orbits with rotation number $n-1$. See [Sh] and the references therein about these results.

Problem: *prove Ivrii's conjecture for 3-periodic multidimensional outer symplectic billiards with respect to a strictly convex closed hypersurface.*

Billiards and Quantitative Symplectic Geometry - Serge Tabachnikov - Problem 8

O / open | AMR 问题清单汇编

Approximating a convex curve by polygons with respect to the symmetric difference.. A popular topic in convex geometry is the approximation of smooth convex closed curves by polygons, see [Gr]. The quality of approximation by n-gons may be measured by the difference of perimeters or areas, and the polygons may be inscribed or circumscribed. This leads to four functions of n, and these four functions correspond to the minimal actions of four billiards: the conventional, Birkhoff, billiards, the outer billiards, the symplectic billiards, and the outer length billiards (see [AT24,BBF] about these lesser studied billiards).

Consider the approximation of an oval by n-gons where the quality of approximation is measured by the area of the symmetric difference.

Problem: *is the resulting function of n related to some billiard-like dynamical system?*

06700 | AMR-129-0022

Billiards and Quantitative Symplectic Geometry - Serge Tabachnikov - Problem 9

O / open | AMR 问题清单汇编

Optical transformations of the space of oriented lines.. The billiard (optical) reflection is a (local) symplectic transformation of the space of oriented lines (rays of light); this space carries a symplectic structure induced by the canonical symplectic structure of the cotangent bundle of the ambient n-dimensional space via symplectic reduction.

The space of oriented lines has dimension $2n-2$, and its symplectic transformation depends on a smooth function of $2n-2$ variables (for example, an infinitesimal symplectic transformation, i.e., a Hamiltonian vector field, is defined by its Hamiltonian function).

On the other hand, a smooth mirror is a hypersurface, locally the graph of a function of $n-1$ variables. Such functions constitute a minuscule part of the space of smooth functions of $2n-2$ variables. Thus, one expects the *optical* set of (local) symplectic transformations of the space of rays that are realized by a finite collection of mirrors to be a very small part of the set of all (local) symplectic transformations of the space of rays.

Problem: *how to characterize this optical symplectic transformation within the space of all symplectic transformations of the space of oriented lines?*

See [PTT,Pe,Ta20,Gl1] for some results in this direction.

Extend Rips' theory to higher-dimensional buildings, e.g. products ofR-trees. Rank rigidity. Let X be a CAT (0) metric space. The space X is said to be or rank ≥ n if every geodesic segment in X is contained in a subset E which is isometric to a flat n-dimensional parallelepiped. If Y is a locally CAT (0) metric space, then Y is said to have rank ≥ n if its universal cover is of rank ≥ n. The rank rigidity theorem proven by Ballmann [1] and by Burns and Spatzier [15, 16] states that: If M is a compact nonpositively curved Riemannian manifold of rank ≥ 2, then either M admits a finite cover the universal cover of M splits (nontrivially) as a Riemannian direct product or M is a locally symmetric space.

06732 | AMR-061-0023

Boundaries of Groups and Kleinian Groups - Problem 23

O / open | AMR 问题清单汇编

Define a topology on the set of quasi geodesics in a (proper geodesic, or coarsely homogeneous, or cocompact) CAT (0) space which (1) has a description as an increasing union of compact metrizable spaces (2) has an inclusion of its visual boundary ∂∞X into it (3) is quasi-isometry invariant (4) has reasonable measure classes which are quasipreserved According to a theorem by Brian Bowditch and Gadde Swarup [13, 56], if G is a 1-ended hyperbolic group then ∂∞G has no cut points. For G a CAT(0) group, a theorem of Eric Swenson says that if c ∈ ∂∞G is a cut point, then there is an infinite-torsion subgroup of G fixing c.

06733 | AMR-061-0024

Boundaries of Groups and Kleinian Groups - Problem 24

P / partially_solved | AMR 问题清单汇编

Any CAT (0) group has no infinite-torsion subgroups. A Euclidean retract is a compact space that embeds into some Rn as a retract. A compact metrizable space Z is a Z-set in ˜X if it is “homotopically negligible” (for every open U ⊂ ˜X, the inclusion U \mathbb{Z} in U is a homotopy equivalence). A Z-structure on a group G is a pair (˜X, Z) such that • ˜X is a Euclidean retract, • Z is a Z-set in ˜X, • X:= ˜X \ Z admits a covering space action of G with X/G compact, • the set of translates of any compact set K ⊂ X is a null sequence in ˜X (that is, for each ϵ > 0 there are only finitely many translates with diam > ϵ). Finally, Z is a boundary of G (or Z-structure boundary) if there exists a Z-structure (˜X, Z) on G. The above notion boundary of G was generalized by T. Farrell and J. Lafont as follows: An EZ-boundary of a group G is a boundary Z = ∂EZ G so that the action of G on X extends to topological action of G on Z.

Boundaries of Groups and Kleinian Groups - Problem 85

P / partially_solved | AMR 问题清单汇编

Find a “constructive” proof of the above theorem. More precisely, consider a finite presentation ⟨g1,.., gk|R1,.., Rm⟩ of G. Given [ρ] ∈ D n(G) define Bn([ρ]):= inf x∈Hn max i=1,...,k d(x, ρ(gi)(x)). Find an explicit constant C, which depends on n, k, m and the lengths of the words Ri, so that the function Bn: Dn(G) →R is bounded from above by C.

06813 | AMR-142-0002

Branko Grunbaum in Many Dimensions - Conjecture 2

O / open | AMR 问题清单汇编

The Four Color Theorem for planar graphs is equivalent to the statement that the dual graph of every triangulated 2-sphere is 3-edge colorable. This is essentially Tait's 1880 observation that the Four Color Theorem is equivalent to showing that every cubic bridgeless planar graph is 3-edge colorable [Tait1880].

In 1968, Gr\"unbaum conjectured a beautiful generalization.

If $ G $ is a simple loopless triangulation of an orientable surface S, then the dual graph of $ G $ is 3-edge-colorable.

背景链接：https://arxiv.org/abs/1901.08622

06814 | AMR-142-0003

Branko Grunbaum in Many Dimensions - Conjecture 3

O / open | AMR 问题清单汇编

Still, this leaves the question open for genus g with $1 \le g \le 4$. In particular, the following seems to be open.

If $ G $ is a simple loopless triangulation of a torus, then the dual graph of $ G $ is 3-edge-colorable.

背景链接：https://arxiv.org/abs/1901.08622

06815 | AMR-142-0006

Branko Grunbaum in Many Dimensions - Conjecture 6 (Ramos's conjecture)

O / open | AMR 问题清单汇编

According to Florian Frick, there is reason to think that the answer is yes. Let $\Delta(j,k)$ denote the minimum dimension d such that every set of j objects in $\mathbb{R}^d$ can be simultaneously partitioned into 2^k equal pieces by k hyperplanes.

For every $j, k \ge 1$, $$\Delta(j,k) = \left\lceil \frac{2^k - 1}{k} j \right\rceil.$$

06816 | AMR-142-0007

Branko Grunbaum in Many Dimensions - Conjecture 7

O / open | AMR 问题清单汇编

[Gr\"unbaum--Kalai--Sarkaria] For every $d \ge 1$ there is a constant C_d such that $$f_d (S)\le C_d f_{d-1}(S)$$ for every d-complex S which is embeddable in $\mathbb{R}^{2d}$.

背景链接：https://arxiv.org/abs/1901.08622

06817 | AMR-142-0008

Branko Grunbaum in Many Dimensions - Conjecture 8

O / open | AMR 问题清单汇编

Various formulations of this conjecture have apparently been discussed for some time---see, for example, Dey [Dey93]. Work of Kalai and Sarkaria [Kalai91,Sarkaria92] suggests a precise formulation, which would in particular give the best possible constant C_d in every dimension. Gr\"unbaum wrote that this question is ``still'' open in his 1970 article, but so far I have not been able to find any earlier reference to it in the literature.

Another possible generalization of the inequality for planar graphs $ e \le 3v$ would be to show that

For every $d \ge 1$ there is a constant C_d such that $f_d \le C_d f_0^d$

Is the fundamental group of a closed manifold without conjugate points semihyperbolic?

The record reads:

It adds that semihyperbolicity was introduced by Alonso and Bridson to describe non-positive curvature on a large scale. The wording is unambiguous; the AIM spelling is “semihyperbolic” (some later papers write “semi-hyperbolic”). Here “closed” means compact without boundary, the metric is Riemannian, and “without conjugate points” applies to that metric.

Let \(M\) be such a manifold, let \(X=\widetilde M\), and let \(\Gamma=\pi_1(M)\) act on \(X\) by deck transformations. A standard consequence of compactness and absence of conjugate points is that \(\exp_x:T_xX\to X\) is a diffeomorphism for every \(x\in X\). Thus any two points of \(X\) are joined by a unique minimizing geodesic. This fact is recorded explicitly by Ivanov--Kapovitch.

Central twists and the G2 locus of Painleve VI surfaces

P / partially_solved | AIM 研讨会问题汇编

It asks for a theory of the different wild-Hitchin realizations of one abstract hyperkähler manifold and proposes, as a first case, the complex two-dimensional \(D_4\)/Painlevé VI space: rank-two logarithmic connections on \(\mathbb P^1\) with four simple poles. The record asks in particular to “find all the possible representations of this space.” Its remarks propose rank-changing realizations via Fourier-Laplace transform or Katz middle convolution and cite the \(G_2\) realization in arXiv:1305.6594.

The request is a classification program, not a yes/no conjecture. In particular, “realization” and its equivalence relation are not defined in the source. This report therefore does **not** claim an exhaustive classification. It gives (i) a hierarchy of structures that a realization may preserve, (ii) a proved eightfold nonuniqueness obstruction for the ordered Painlevé VI trace data, and (iii) an exact trace-parameter criterion for reaching the symmetric Fricke subfamily, and hence the known \(G_2\) Betti realization, by central twists.

Classification of Finite Metric Spaces and Combinatorics of Convex Polytopes

O / open | AMR 问题清单汇编

Let (X,ρ) be a finite metric space. Its fundamental polytope $R_{X,\rho}$ is the convex hull of the vectors $e_{x,y}=(\delta_x-\delta_y)/\rho(x,y)$ for distinct $x,y\in X$; its combinatorial structure is the isomorphism class of the face poset of $R_{X,\rho}$. (1) Express this combinatorial structure, including the f-vector, directly in terms of linear inequalities in the metric ρ. (2) For $|X|=n$, estimate the number of combinatorial structures and its asymptotic growth, especially the number of open (generic) types. (3) Give sufficient conditions for two finite metric spaces to have the same combinatorial structure. (4) Describe the combinatorial types of finite metric spaces that embed isometrically into a Euclidean or Hilbert space; do all combinatorial types occur? (5) Is the stratification of the cone of distance matrices into combinatorial types universal, or are there restrictions on the topological types of its open components?

Closed geodesics in a finite-volume torus ansatz

P / partially_solved | AIM 研讨会问题汇编

Question 2.3.1 (Bangert). Does every complete Riemannian manifold with finite volume have at least one closed geodesic?

The question was answered affirmatively for dimension 2. Moreover, in dimen-sion 2 a complete Riemannian manifold of finite volume even has infinitely many geometrically different geodesics [Bangert1980]. The argument that was used in the proof is based on the Birkhoff minimax procedure we recalled in the beginning of §2, and does not work in dimensions ≥ 3. One can even hope to construct coun-terexamples in the class of Liouville-integrable geodesic flows. In this case, most orbits of the geodesic flow are rational or irrational windings on the Liouville tori; they are closed, if all of the corresponding frequencies are rational. Since there are essentially (n - 1) frequencies in dimension n, one can hope that if n > 2 it would be possible to ensure that there is always at least one irrational frequency. Initial attempts to find a counterexample on T 2 × R with the metric of the form

a(r)dφ 2 + b(r)dψ 2 + dr 2 were, however, unsuccessful. A more difficult problem would be to prove that on any complete Riemannian manifold of finite volume there exist infinitely many closed geodesics.Questions of this nature are also interesting in the realm of Finsler geometry. One would expect the results for reversible Finsler metrics to be very similar to those for Riemannian metrics. For irreversible Finsler metrics, Katok's example shows that there are compact Finsler manifolds with only finitely many closed geodesics, but it is still possible that all non compact Finsler manifolds with finite volume might have infinitely many closed geodesics. On the other hand, the following question is completely open:

06869 | AIM-GEOMETRY-0166

Closure repair and instantaneous smoothing of the topologist's sine curve

O / open | AIM 研讨会问题汇编

Let $C\subset\mathbb{R}^2$ be the topologist's sine curve. More precisely, \[C=\left\{\left(x,\sin\frac1x\right):x\in\left(0,\frac1{2\pi}\right)\right\}\cup\Gamma, \] where Γ is a smooth curve connecting the origin and $(1/(2\pi),0)$ that does not intersect $C\setminus\Gamma$. What happens under level-set flow? Does it become instantly smooth? More generally, what happens to a compact set in $\mathbb R^2$ under level-set flow?

There is a genuine formulation defect. Put \[a=\frac1{2\pi},\qquad G=\left\{\left(x,\sin\frac1x\right):0<x<a\right\},\qquad V=\{0\}\times[-1,1]. \] Then \[\overline G=G\cup V\cup\{(a,0)\}, \] and, because $(a,0)\in\Gamma$, \[\overline{C}=G\cup\Gamma\cup V. \tag{1.1} \] Thus the displayed set is bounded but is not closed, and hence is not compact, unless the unmentioned exceptional possibility $V\subset\Gamma$ occurs. Under the source-verified intended reading, Γ is an embedded arc disjoint from $G\cup V$ except at its endpoints, so the literal displayed set definitely omits V and is noncompact.

This matters because Lam--Lauer's geometric definition begins: “Let $K\subset\mathbb R^{n+1}$ be compact,” both for weak-set flow and level-set flow. The literal C is outside that definition.

The intended repair is nevertheless verified, not guessed: Lam--Lauer Definition 1.3 defines their topologist's sine curve T as the union of the oscillating graph, the full compactifying segment V, and a smooth connecting arc. Therefore this report separates:

1. **Literal reading:** $C_{\mathrm{lit}}=G\cup\Gamma$, not admissible compact data. 2. **Closure reading:** $T=\overline{C_{\mathrm{lit}}}=G\cup\Gamma\cup V$. 3. **Verified intended reading:** exactly the Lam--Lauer compact set T, up to the inessential choice of graph cutoff and connecting arc.

The exact stored formulation is classified as invalid, but its verified intended problem is solved.

Cohn--Elkies magic functions solve sphere packing in dimensions 8 and 24

S / solved | AIM 研讨会问题汇编

Question 1. Can the technique of Cohn-Elkies prove that the E8 and Leech lattices have the highest sphere packing densities in dimensions 8 and 24, respectively?

The wording is unambiguous. The preceding source text explicitly discusses packings “lattice or not,” and the sentence following the question says that a positive answer gives the complete sphere-packing solution in dimensions \(8\) and \(24\). Thus this asks for optimality among all packings, not merely among lattice packings.

Combinatorial Khovanov-to-Floer differentials and a determinant rank budget

S / solved | AIM 研讨会问题汇编

Peter Ozsvath discussed the problem of computing Ozsvath and Szabo's invariants combinatorially or axiomatically. Their theory lies somewhere between combina-torial invariants, which are easy to compute but not very useful, and invariants defined in terms of PDE's, which are very useful but hard to compute. "Right next door" is Khovanov's categorification of the Jones polynomial, which looks like a Floer theory but is defined purely combinatorially. In fact there is the following bridge between them: given a link K in S3,there is a spectral sequence whose E2 term is the Khovanov homology of K (with Z/2 co-efficients) and which converges toˆ HF (Σ 2(K)), where Σ2(K) denotes the double cover of S3 branched along K. Question: can one compute the differentials in the spectral sequence combinatorially? Also,ˆ HF (Σ 2(K)) has applications to slice genus bounds: can Khovanov homology say anything about the 4-ball genus?

Compact tropicalization, Monge-Ampère, curve realizability, and a sharp circle model

P / partially_solved | AIM 研讨会问题汇编

This record is item A.23, contributed by Ilia Zharkov, in the AIM workshop notes *Amoebas and tropical geometry*. Comparison with the source PDF shows that “Chapter B: Snapshot of the pre-open problem session” begins a new chapter and is not part of A.23. The present job therefore owns only A.23, not the trailing chapter material.

1. **Compact tropical varieties.** For a compact complex algebraic variety, can one naturally modify the valuation map to obtain a compact tropical variety, retaining as much affine structure as possible? The text anticipates a role for a polarization (a tropical Kähler class) but expects the affine structure itself to be algebro-geometric. 2. **Tropical Monge-Ampère / Calabi problem.** In an affine chart \(U\subset B_0\), a potential \(K\) is represented by the graph \[dK\subset \mathbb R^n\times(\mathbb R^n)^*. \] The smooth graph should be replaced tropically by a piecewise-linear one and the Monge-Ampère equation interpreted distributionally. Is there a tropical Monge-Ampère operator whose solution produces a unique Monge-Ampère measure in a polarization class \[H^1(B,\operatorname{Aff}(B,\mathbb R))? \] 3. **Curve counting and realizability.** Can tropical Gromov-Witten calculations be performed on a Calabi-Yau? Is there a simple rule deciding which tropical curves are limits of classical curves, given that in higher dimensions some tropical curves are not realizable?

The PDF itself contains “deleting pseudo-pods”; this unusual phrase is not silently corrected. The malformed strings “Monge-Amp` ere,” “K¨ ahler,” “C∞,” “Rn,” and “(Rn)∗” have been recovered as “Monge-Ampère,” “Kähler,” \(C^\infty\), \(\mathbb R^n\), and \((\mathbb R^n)^*\).

Complex sectional curvature blow-up at high-codimension fixed sets

P / partially_solved | AIM 研讨会问题汇编

Let $M_\epsilon =M\times_{S^1} (\epsilon S^1)$. As $\epsilon \to 0$, is Riem(Curvature Operator) bounded below?

Is there a constant $C<\infty$, independent of sufficiently small ϵ, such that every complex sectional curvature of (M,g_ϵ) is at least $-C$? If not, which orbit types obstruct such a bound?

This sentence is incomplete in isolation.

A circle acts isometrically on a Riemannian manifold (M,g), and g_ϵ is the Cheeger-deformed metric induced by the Riemannian submersion

\[\pi_\epsilon:(M,g)\times(\epsilon S^1)\longrightarrow M\times_{S^1}(\epsilon S^1)\cong M. \tag{1.1} \]

Here the diagonal circle action is free because it translates the second factor, and the generator of the second circle has length ϵ. The report asks whether the curvature operators of g_ϵ have a lower bound independent of ϵ. It records positive regimes when the action is almost free or its fixed-point set has codimension two, and reports a negative flat linear model when the fixed-set codimension is greater than two.

I use the Riemannian complex-sectional-curvature convention of Ni--Wolfson: the tangent space and curvature tensor are complexified, and the curvature is tested on every complex decomposable two-vector. This convention is defined precisely in Section 3. A competing convention tests only totally isotropic complex two-planes. The counterexample below uses a totally isotropic plane, so it is negative under both conventions. “Holomorphic sectional curvature” on a manifold equipped with an almost-complex or complex structure is a different notion and cannot be the intended general question because the AIM setup assumes no such structure.

Conditional identification of the Cohn--Miller limits and exact quadratic moments

P / partially_solved | AIM 研讨会问题汇编

Question 4. What are the purported limits of the Cohn-Miller sequences? Can the observed rationalities in their Taylor coefficients be explained? Are there others outside from the quadratic terms? Contributed by Peter Sarnak and Andreas Str¨ ombergsson [followed by an Epstein-zeta paragraph].

Question 4 ends after “quadratic terms?” The contributor line and the Epstein-zeta paragraph begin a new item and are not part of Question 4. Accordingly, this report treats only the three questions about the Cohn--Miller sequences.

In Cohn and Miller [CM], the relevant objects are radial polynomial-times-Gaussian auxiliary functions in dimensions 8 and 24. The finite functions have prescribed roots inspired by the nonzero vector lengths of E_8 and the Leech lattice. A naive exact-root sequence fails to converge numerically, so [CM, (3.5)] perturbs the outer roots. For every fixed lattice shell, however, the perturbed root eventually equals the true shell radius. Cohn and Miller conjecture that the resulting functions f_k and their Fourier transforms converge locally uniformly in a complex neighborhood of the real axis [CM, Conjecture 4.1].

Throughout, the Fourier transform is

\[\widehat f(y)=\int_{\mathbb R^d}f(x)e^{-2\pi i\langle x,y\rangle}\,dx. \]

Conformal-primitivity obstruction and curvature-only rigidity on surfaces

P / partially_solved | AIM 研讨会问题汇编

Let \(M^n\) be a closed manifold, with orientation if density-valued invariants are written as \(n\)-forms. Closedness is inherited from the surrounding compact-manifold discussion; the displayed one-line conjecture does not repeat it. All local invariants in this passage are being treated as densities. If \(\mathbf S_g\) is a natural \(n\)-density and \[\int_M \mathbf S_g \] is invariant under \(g\mapsto e^{2\omega}g\), then the conjecture asserts that \[\mathbf S= a\mathbf Q+\mathbf L+\mathbf G, \] where \(a\) is constant, \(\mathbf Q\) is a chosen Branson \(Q\)-curvature density, \(\mathbf L\) is a local conformal invariant density, and \(\mathbf G\) has a **local conformal primitive**. The last condition means that there is a natural local density \(\mathbf F_g\) such that, for every smooth \(\varphi\), \[\left.\frac{d}{dt}\right|_{t=0} \int_M \mathbf F_{e^{2t\varphi}g} =\int_M \varphi\,\mathbf G_g. \]

The nearby text first defines a conformal primitive more generally as a two-metric functional on a fixed conformal class. If \(\hat g=e^{2\omega}g\), then \[c(\hat g,g):=\omega. \] A two-metric primitive \(\mathcal A(\hat g,g)\) is required to be alternating, cocyclic, \[\mathcal A(g_2,g_0)=\mathcal A(g_2,g_1)+\mathcal A(g_1,g_0), \] and to have the required first variation when its first metric is varied and its second is held fixed. A **local** primitive is the special coboundary \[\mathcal A_F(\hat g,g)=\int_M(\mathbf F_{\hat g}-\mathbf F_g) \] arising from one local invariant \(\mathbf F\).

The extracted formula following the conjecture is \[\frac12\int_M c(\hat g,g) \bigl(\mathbf L_{\hat g}+\mathbf L_g\bigr). The phrase “the The \(Q\)” is a genuine duplicated-word typo in the PDF and is read as “The \(Q\).” The text also says that the chosen \(Q\) is not unique: changing it by a local conformal invariant merely changes \(\mathbf L\).

Convex 'Fair' Partitions Of Convex Polygons

P / partially_solved | Open Problem Garden

Basic Question: Given any positive integer n, can any convex polygon be partitioned into n convex pieces so that all pieces have the same area and same perimeter?

Definitions: Define a Fair Partition of a polygon as a partition of it into a finite number of pieces so that every piece has both the same area and the same perimeter. Further, if all the resulting pieces are convex, call it a Convex Fair Partition.

Questions: 1. (Rephrasing the above 'basic' question) Given any positive integer n, can any convex polygon be convex fair partitioned into n pieces?

2. If the answer to the above is "Not always", how does one decide the possibility of such a partition for a given convex polygon and a given n? And if fair convex partition is allowed by a specific convex polygon for a give n, how does one find the optimal convex fair partition that minimizes the total length of the cut segments?

3. Finally, what could one say about higher dimensional analogs of this question?

Conjecture: The authors tend to believe that the answer to the above 'basic' question is "yes". In other words they guess: Every convex polygon allows a convex fair partition into n pieces for any n

Convexity obstruction and a fat-Cantor geometric embedding

P / partially_solved | AIM 研讨会问题汇编

Can one identify a geometric example of a system for which the set of phase transitions has positive Lebesgue measure?

It does not name a parameter or define “phase transition.” The immediately preceding problem 3.3 asks about the inverse-temperature family $\{q\varphi\}_{q\in\mathbb R}$ and the pressure of the geometric potential for a nonpositively curved surface. The best-supported reconstruction is therefore: for a geometrically defined system and a distinguished potential φ, can the exceptional set for $q\mapsto P(q\varphi)$ have positive one-dimensional Lebesgue measure?

Four inequivalent exceptional sets must be separated:

1. **first-order:** $P(q\varphi)$ is not differentiable; 2. **analytic:** $P(q\varphi)$ is not real analytic in any neighborhood of q; 3. **coexistence:** $q\varphi$ has multiple equilibrium states; 4. **recurrence/existence:** an equilibrium state appears, disappears, or changes recurrence class.

06985 | AIM-GEOMETRY-0406

Critical Weinstein surgery, cyclic chord words, and finite action windows

P / partially_solved | AIM 研讨会问题汇编

This is Question 1.10 in the AIM workshop list *Holomorphic curves in contact geometry*. It asks how contact homology changes under the handle decomposition of a Stein filling. The critical case is attachment of a middle-index Weinstein handle along a Legendrian sphere \(L\); the source observes that new closed Reeb orbits should be concatenations of Reeb chords of \(L\), and asks for a surgery formula in terms of the relative contact homology of \(L\).

The symbols in the official source are \(W\) for the Stein filling, \(\varphi:W\to\mathbb R\) for a pseudoconvex function, and \(L\) for the Legendrian attaching sphere. It is the running page number at the PDF page break. AIM's official HTML transcription omits it and continues directly with the critical-handle paragraph. No mathematical clause is missing there.

In modern language, take a \(2n\)-dimensional Weinstein domain \(X_0\), a Legendrian attaching link \(\Lambda\subset\partial X_0\) of \((n-1)\)-spheres, and let \(X=X_0\cup H^n_\Lambda\). The one-sphere case in the AIM question is included by taking one component.

06988 | AIM-GEOMETRY-0367

Critical-weight conformal invariants built from Schouten jets

P / partially_solved | AIM 研讨会问题汇编

Problem 10: If n ≥ 4 is even, is there a nonzero scalar conformal invariant of weight -n

which is expressible as a linear combination of complete contractions of the tensors ∇lP,

l ≥ 0? If the answer to this question is no, then the Q-curvature defined via the ambient metric construction is uniquely determined by its transformation law in terms of the GJMS operator

n = 4, as is the norm squared of the ambient obstruction tensor in higher even dimensions.

Its mathematical typography is \(\nabla^lP\), meaning the \(l\)-th covariant derivative of the Schouten tensor, and \(P_n\), meaning the critical order-\(n\) GJMS operator. No missing qualifier was found.

The source alternates between scalar and density language elsewhere in the workshop document. Here “scalar conformal invariant of weight \(-n\)” is recovered as a scalar function \(I_g\) satisfying

\[I_{e^{2\omega}g}=e^{-n\omega}I_g. \]

Equivalently, \(I_g\,dv_g\) is a conformally invariant density. For scalar \(Q\)-curvature, the corresponding transformation law is

\[e^{n\omega}Q_{e^{2\omega}g}=Q_g+\mathcal P_{n,g}\omega, \]

where \(\mathcal P_n\) is used in this report for the critical GJMS operator, to distinguish it from the Schouten tensor \(P_{ij}\). In density notation the factor \(e^{n\omega}\) is absorbed into the volume form.

P / partially_solved | AIM 研讨会问题汇编

Let \(X\) be really full rank. This implies there is a torus of dimension the number of frozen variables acting on \(X\) preserving cluster structure. \(S\) acts freely on each cluster torus so any point with nontrivial \(S\)-stabilizers is in \(P\).

In \(G(k,n)\), nontrivial stabilizers correspond to disconnected matroids. So if \([v_1,\dots,v_n]\) is a \(k\times n\) matrix where the matroid of \(v_1,\dots,v_n\) is disconnected, this point of \(G(k,n)\) is in \(P\).

Is the converse also true (Is \(P\) for the big positroid cell exactly the points with disconnected matroid)?

Deterministic lift escape and the centered torus cocycle

P / partially_solved | AIM 研讨会问题汇编

Question 8.3.1 (Benjamin Schmidt). Which of these sets has full measure?

Let (M^2,g) be a closed surface whose geodesic flow $\phi^t:SM\to SM$ is ergodic for Liouville measure. For $v\in SM$, let $\gamma_v:\mathbb R\to M$ be its unit-speed geodesic and let $\widetilde\gamma_v:\mathbb R\to\widetilde M$ be any lift. The source defines $$\begin{aligned} T_b&=\{v\in SM:\widetilde\gamma_v(\mathbb R) \text{ is contained in a bounded subset of }\widetilde M\},\\ T_p&=\{v\in SM:\widetilde\gamma_v \text{ is unbounded and approaches infinity properly}\},\\ T_i&=SM\setminus(T_b\cup T_p). \end{aligned}$$ The PDF prints TM rather than SM in the last line, but the paragraph begins with $v\in SM$ and all three sets partition unit tangent vectors, so SM is the consistent reading. The source states that the sets are measurable and invariant, hence ergodicity makes exactly one full measure.

The exact problem is:

The acknowledgements identify the participating Schmidt as Benjamin Schmidt. The following source commentary predicts T_i on the torus and T_p on surfaces of genus at least two, discusses minimizing geodesics, and says the question makes sense in all dimensions. The page header “KEITH BURNS AND VLADIMIR S. MATVEEV” is not part of the problem. All text beginning with “8.4. Generic metrics” is spill from the next section and is excluded.

The source does not formalize “approaches infinity properly.” Here it has its standard two-sided meaning: $\widetilde\gamma_v:\mathbb R\to\widetilde M$ is a proper map, equivalently $$d(\widetilde\gamma_v(0),\widetilde\gamma_v(t))\longrightarrow\infty\quad\text{as }|t|\to\infty. \tag{1.1}$$ All results below also have the evident one-sided version if only $t\to+\infty$ was intended.

Dimension-four Schouten-jet uniqueness and a two-obstruction reduction

P / partially_solved | AIM 研讨会问题汇编

If the answer is yes, then this gives a characterization of the GJMS operator \(P_n\). Combined with a negative answer to Problem 11, this would provide a unique specification of \(Q\).

This reconstruction is source-verified, but the self-reference is almost certainly a typographical error: the preceding Problem 10 asks whether a weight-\(-n\) scalar conformal invariant can be made purely from \(\nabla^IP\), and that is exactly the complementary condition needed to specify \(Q\). Replacing the printed second “Problem 11” by “Problem 10” is therefore a logical inference, not verified wording.

Here \(P_{ij}\) is the Schouten tensor, not the GJMS operator; to prevent collision this report writes the Schouten tensor as \(\mathsf P\) and the critical GJMS operator as \(P_n\).

Energy and spectral-gap gates for Lagrangian corners

P / partially_solved | AIM 研讨会问题汇编

Question 1.12. In setting up such an extended field theory picture, it is important to formulate holomorphic curve theory for manifolds with boundary, or open manifolds with some asymptotic conditions. The basic idea is that when you replace boundary conditions with asymptotic conditions, you get more information about and control over how you approach the boundary. For example, if you are looking at holomorphic curves with boundary in a Lagrangian, it is sometimes better to consider curves with asymptotics in the unit cotangent bundle of the Lagrangian. More generally, for the extended field theory picture, one may need to consider holomorphic curves with boundary along some Lagrangian cylinders, and then you have holomorphic curves with corners, two different types of asymptotic conditions...

Energy-normalized Hopf defect and a curvature-sign rigidity theorem

P / partially_solved | AIM 研讨会问题汇编

Question 7.4.1 (Paternain). Consider a magnetic flow on a closed surface of genus

≥ 2 and an energy level such that the topological entropy vanishes. Suppose that the magnetic geodesics on this level do not have conjugate points. Is the system locally symmetric in the sense that the metric has constant curvature and the magnetic form is a constant multiple of the volume form?

Many of the earlier questions in this section can also be asked about magnetic geodesics lying on a certain (possibly sufficiently high) energy level. Let us men-tion [Bialy2000], where a natural analog of Theorem 7.0.2 was proved under the assumption that the metric is conformally flat, and it was conjectured that this assumption is not essential. 8. Unrestricted curvature

8.1. Ergodic geodesic flows. Does every closed manifold (with dimension ≥ 2)admit a metric (Riemannian or Finsler) with ergodic geodesic flow?

This is known for surfaces [Donnay1988II], for 3-manifolds [Katok1994], for prod-uct manifolds in which the factors have dimenson ≤ 3 [Bur-Ger1994], and for spheres [Bur-Ged]. Donnay and Pugh have shown that any embedded surface can be perturbed, in the C0 topology to an embedded surface whose geodesic flow is ergodic [Don-Pugh2004]. These constructions all make essential use of the focusing caps introduced by Donnay in [Donnay1988I]. The general problem is still wide open despite some reports of its solution (p. 87 of [Berger2000] and Section 10.9 of [Berger2003]). 8.2. Positive curvature.

Hilbert schemes of points on \(K2\)-surfaces.

There are \(12\) known deformation classes of complete hyperkahler manifolds of real dimension four that arise as moduli spaces of meromorphic Higgs bundles. Lets call them \(K2\) surfaces. For each of these \(K2\) surfaces there is a sequence of Higgs bundle moduli space of dimension \(4n\) for each \(n\).

Is each of these \(4n\) dimensional hyperkahler manifolds diffeomorphic to (or a deformation of) the Hilbert scheme of \(n\)-points on the underlying \(K2\) surface?

Recovered question. For generic admissible parameters and each of the twelve two-dimensional tame or wild meromorphic Hitchin moduli spaces \(S\) listed by Boalch, is the corresponding higher-dimensional moduli space \(\mathcal H_n\) diffeomorphic to \(S^{[n]}=\operatorname{Hilb}^n(S)\), or related to it by a topology-preserving deformation?

07156 | AIM-GEOMETRY-0309

Euler-ideal kernel for the locally-free locus of a circle representation

P / partially_solved | AIM 研讨会问题汇编

The final line is the heading of the next section and is not part of Question 7.3. The hyphen in “representations” is a line-break artifact.

The preceding page supplies the intended context. A compact Lie group \(G\) acts linearly and Hamiltonianly on \(V=\mathbb C^n\). For central regular values \(\alpha\), the list first considers the usual Kirwan maps \[\kappa_\alpha:H_G^*(V)\cong H^*(BG)\longrightarrow H^*(V/\!/_\alpha G). \] It then prints \[X:=\bigl(V\setminus\{\text{points where \(G\) fails to act locally freely}\}\bigr)/G_{\mathbb C}. \] This printed definition is inconsistent with the very next display, \(H^*(X/G)=H_G^*(X)\): if \(X\) has already been divided by \(G_{\mathbb C}\), there is no such residual \(G\)-action in general. Moreover the map induced by inclusion is defined on the prequotient open set. The only coherent recovery is therefore to set \[\widetilde X:=\{v\in V:G_v\text{ is finite}\}, \] the **locally-free locus**, and to recover the question as: \[\boxed{\text{Is }i^*:H_G^*(V)\cong H^*(BG)\longrightarrow H_G^*(\widetilde X)\text{ surjective, and what is }\ker i^*?} \tag{Q} \] The slash notation in the source may then be interpreted as the quotient orbifold/stack \([\widetilde X/G]\). For a locally free compact action, \(H_G^*(\widetilde X;\mathbb Q)\) is the ordinary cohomology of the orbifold classifying space and agrees with the rational cohomology of the coarse orbit space under the standard finite-isotropy comparison. It is not the Chen--Ruan cohomology ring, which has additional twisted sectors.

07162 | AIM-GEOMETRY-0003

Exact directional energies and sharp Hessian comparison for boxes

P / partially_solved | AIM 研讨会问题汇编

For a bounded convex \(\Omega\subset\mathbb R^n\), let \[-\Delta u=\lambda_1(\Omega)u,\qquad u|_{\partial\Omega}=0, \qquad u>0,\qquad \|u\|_{L^2(\Omega)}=1, \] and, for \(|\xi|=1\), define \[P(\xi)=\int_{\partial\Omega}|\xi\cdot\nabla u|^2\,dS, \qquad Q(\xi)=\int_\Omega|\xi\cdot\nabla u|^2\,dx. \tag{1} \] The first question asks for a relation between these boundary and interior directional energies. The second is David Jerison's dimension-uniform Hessian conjecture: if \(p^*\) is the maximum point of \(u\), is there \(C_n\) such that, for every \(p\) with \(u(p)>u(p^*)/2\), \[\frac1{C_n}\bigl(-\nabla^2\log u(p)\bigr) \preceq -\nabla^2\log u(p^*) \preceq C_n\bigl(-\nabla^2\log u(p)\bigr)? \tag{2} \] Here \(\preceq\) is Loewner order on symmetric matrices.

The source has three textual issues.

1. “Dirichet” is only a spelling error for “Dirichlet.” 2. After defining \(Q(\xi)\), it states \(Q(\Omega)\le c/\operatorname{inradius}(\Omega)^2\), but \(Q(\Omega)\) is never defined. The safe repair is either the pointwise assertion \[Q(\xi)\le \frac{c_n}{r(\Omega)^2}\quad(|\xi|=1), \tag{3} \] or the same assertion after defining \(Q(\Omega):=\sup_{|\xi|=1}Q(\xi)\). Both follow immediately from \[Q(\xi)\le\int_\Omega|\nabla u|^2=\lambda_1(\Omega) \le\lambda_1(B_{r(\Omega)}) =\frac{j_{n/2-1,1}^2}{r(\Omega)^2}. \tag{4} \] The middle inequality is Dirichlet domain monotonicity because an inball lies in \(\Omega\). I do not claim to know which of the two repairs the author intended. 3. The sentence that \(Q\) is “the projection body function for volume” is terminologically unclear. Extended off the unit sphere, \(Q\) is a quadratic form in \(\xi\), whereas the classical projection-body support function is degree-one homogeneous. No argument below relies on this sentence.

Exact membership of the origin in an ideal amoeba

S / solved | AIM 研讨会问题汇编

A.3 Membership problems. For every ideal $\mathfrak a$ in \[R_d=\mathbb Z[x_1^{\pm1},\ldots,x_d^{\pm1}] \] there is a related dynamical system generated by d commuting automorphisms of a compact abelian group via Pontryagin duality. For dynamics it is very important to determine when such systems have a finiteness condition called expansiveness. A theorem of Klaus Schmidt states in effect that when $\mathfrak a$ contains no nonzero integers, then the system is expansive if and only if the complex amoeba of $\mathfrak a$ does not contain the origin.

Question. Is there an algorithm to determine whether the complex amoeba of an ideal $\mathfrak a$ in R_d contains the origin? (Contributed by Manfred Einsiedler and Doug Lind.)

Exactification and the marked/unmarked cotangent boundary

P / partially_solved | AIM 研讨会问题汇编

Question 1.30 (Eliashberg). Do symplectic and contact invariants of the cotangent bundle of a smooth manifold \(M\) remember the topology of \(M\)? For example, if \(M_1\) and \(M_2\) are homeomorphic but not diffeomorphic (e.g. exotic spheres), can one detect this by showing that \(T^*M_1\) and \(T^*M_2\) are not symplectomorphic, or that \(ST^*M_1\) and \(ST^*M_2\) are not contactomorphic? Related question: is the natural map from knots in \(S^3\) to Legendrian tori in \(ST^*S^3\cong S^3\times S^2\) injective? Ng's work is the first result in this direction.

Exactness and topology in the higher-genus adiabatic limit

P / partially_solved | AIM 研讨会问题汇编

A.13 Moduli space of holomorphic polygons. Background: In the paper with Fukaya "Zero loop open strings in the cotangent bundle and Morse homotopy", Asian J. Math. 1 (1997), 96--180, we proved that "The moduli space of holomorphic polygons with boundary lying on k-tuples of La-grangian graphs of k-Morse functions is diffeomorphic to that of graph flows of the Morse functions in the adiabatic limit or (in the large complex structure limit). The projections, near the limit, of the holomorphic polygons on the base of the cotangent bundle resembles amoeba-type shapes and it shrinks to the graphs of Morse flows in the limit." In the paper, we dealt with the case of discs, i.e., open Riemann surfaces of genus zero. **Problem:** Study the similar degeneration problem for the higher genus case.

07195 | AIM-GEOMETRY-0006

Exterior Robin optimization at the Steklov threshold

P / partially_solved | AIM 研讨会问题汇编

The AIM record asks, for a fixed volume and dimension \(n\geq 3\), whether the bottom of the Robin spectrum in the exterior of a smooth bounded obstacle has a global maximizer, and whether the fact that a ball is locally but not globally maximizing forces another critical obstacle by a mountain-pass argument.

Several corrections are needed before the question is mathematically unambiguous.

* The opening condition \(\Omega\subset\mathbb R^3\) conflicts with the exterior \(\mathbb R^n\setminus\overline\Omega\); the consistent reading is \(\Omega\subset\mathbb R^n\). * Put \(D=\Omega^{\rm ext}\) and let \(\nu_\Omega\) point outward from the obstacle and into \(D\). The quadratic form in the record, \[q_{\alpha,\Omega}[u]=\int_D|\nabla u|^2\,dx+\alpha\int_{\partial\Omega}|u|^2\,dS, \qquad u\in H^1(D), \] produces \(\partial_{\nu_\Omega}u=\alpha u\). If \(\nu\) instead denotes the outward normal of the exterior domain, the sign is reversed. * The displayed ``minimum'' is an infimum. It is attained when the spectral bottom is a negative discrete eigenvalue, but in general the bottom is \(0\), the lower edge of the essential spectrum, and need not be an eigenvalue. * There is no scale-free dimensional constant \(\alpha_*(n)\). In \(n\geq3\), the threshold is the domain-dependent number \[\alpha_*(D)=-\sigma_1(D), \] where \(\sigma_1(D)\) is the first exterior Steklov eigenvalue.

Thus the recovered problem is to maximize \[\lambda_1^\alpha(D):=\inf_{0\ne u\in H^1(D)} \frac{q_{\alpha,\Omega}[u]}{\|u\|_{L^2(D)}^2} \tag{1} \] over a specified class of smooth bounded obstacles of prescribed volume, while distinguishing optimization of the *spectral bottom* from optimization restricted to obstacles for which that bottom is a negative eigenvalue.

For \(\alpha\geq0\), the quadratic form is nonnegative and the essential spectral edge is \(0\), so \(\lambda_1^\alpha(D)=0\) for every obstacle. Thus the global question is trivial for nonnegative parameters; the nontrivial and discrete-eigenvalue regimes have \(\alpha<0\).

07200 | AIM-CONVEX_GEOMETRY-0045

Extremal slabs, spherical negative moments, and cross-polytope formulas

P / partially_solved | AIM 研讨会问题汇编

This record is the continuation of Problem 23 in the AIM workshop list *Fourier analytic methods in convex geometry*.

For \(t>0\) and \(a\in S^{n-1}\), the PDF defines

\[\operatorname{Sl}(a,t)=\{x\in\mathbb R^n:|x|_\infty\leq 1, |\langle x,a\rangle|\leq t\}, \qquad S(a,t)=\{x:|x|_\infty\leq1,\ \langle x,a\rangle=t\}, \]

and writes \(V(a,t)=\operatorname{vol}_n\operatorname{Sl}(a,t)\) and \(A(a,t)=\operatorname{vol}_{n-1}S(a,t)\). It also sets

\[f_m=\frac1{\sqrt m}(\underbrace{1,\ldots,1}_{m},0,\ldots,0). \]

1. Is the minimum of \(V(a,t)\), over \(a\in S^{n-1}\) for fixed \(t\), always attained at some \(f_m\)? 2. For \(t\leq2\sqrt2-2\), is the minimum attained at \(f_1\)? The source records the real result for \(t\leq3/4\), the complex result for \(t\leq4/5\), and asks whether the complex range extends to \(t_0\simeq0.867\). 3. If \(X_j\) are independent and uniform on \(S^{m-1}\subset\mathbb R^m\), determine the best constants in \[c_p^{-1}|a|_2\leq \left\|\sum_{j=1}^n a_jX_j\right\|_{L_p}, \qquad -m+1<p<0. \] 4. Find an integral formula for symmetric slab volumes and noncentral hyperplane sections of \(B_1^n\), and find the extremal slab directions.

* The PDF writes the cube as \([-1,1]^n\) but immediately quotes \(1\leq A(a,0)\leq\sqrt2\). With ordinary Euclidean section measure the correct bounds for that cube are \(2^{n-1}\leq A(a,0)\leq2^{n-1}\sqrt2\). The displayed bounds are for the volume-one cube \([-\tfrac12,\tfrac12]^n\), or for section volume in \([-1,1]^n\) divided by \(2^{n-1}\). Extremal directions are unaffected by this common factor. * The OCR has \(t(t^2-1)\) in the equation for \(t_0\). This cannot have a root near \(0.867\). The geometrically correct equation, also consistent numerically with the value printed in the PDF, is \[\pi t^2=t(t^2+1)\sqrt{2-t^2} +(2t^2-1)\arcsin\!\bigl(t\sqrt{2-t^2}\bigr). \tag{1} \] A bisection check gives \(t_0=0.8671146218586\ldots\). For \(0\leq t\leq1\), (1) is equivalently obtained by replacing the last arcsine by \(2\arcsin(t/\sqrt2)\).

07221 | AIM-GEOMETRY-0224

Finite marked-length calibration for branched hyperbolic triangulations

P / partially_solved | AIM 研讨会问题汇编

Question 5.1.2 (Schmidt). Does the marked length spectrum determine such a metric (in the class of all locally CAT \((-1)\) metrics on this space, or in the class of all 2-dimensional (metrical) simplicial complexes with the above properties homeomorphic to the given complex)?

The antecedent “such a metric” occurs in the immediately preceding source paragraph (record AIM-GEOMETRY-0223). It means the intrinsic length metric on a two-dimensional metrical simplicial complex \(K\) satisfying:

1. every two-simplex is a hyperbolic geodesic triangle; 2. the metric link condition giving local CAT\((-1)\) holds at every vertex; and 3. every edge belongs to at least two two-simplices.

Thus the complex has no one-sided edge boundary, but it can branch along an edge contained in three or more triangles. The source does not explicitly repeat “finite” or “compact” in this paragraph. The intended marked-length setting, and all later rigidity results discussed below, concern finite/compact quotients; this extra hypothesis is stated whenever used here.

There are two comparison categories in Schmidt's question:

- all locally CAT\((-1)\) metrics on the fixed underlying topological space; or - all piecewise hyperbolic two-dimensional metrical simplicial complexes with the displayed properties and homeomorphic to the given complex.

The second version needs a **marking**. For metrics on the same \(K\), equality means equality as functions on conjugacy classes of \(\pi_1(K)\). For spaces \(K_0,K_1\), one must specify a homeomorphism \(f:K_0\to K_1\) (or an identified fundamental-group isomorphism) and require \[\ell_{g_1}(f_*[\gamma])=\ell_{g_0}([\gamma]) \quad\text{for every conjugacy class }[\gamma]. \] An isometry proving marked rigidity should induce that marking, normally up to homotopy or isotopy. “Homeomorphic” without this datum is not enough to define equality of marked spectra.

The sentences beginning “The questions above are closely related to the boundary rigidity problem” are a transition to Question 5.1.3, not part of Schmidt's marked-length-spectrum question. The standard intended definition is that another **metric** \(g'\) with the same boundary-distance function must make \((M,g')\) isometric to \((M,g)\), through a diffeomorphism fixing the boundary pointwise. This correction is recorded only to disambiguate the transition; boundary rigidity is not the problem studied in this attempt.

Question 6.1.1. Is the geodesic flow of a metric of nonpositive curvature on a closed surface of genus at least \(2\) ergodic with respect to the Liouville measure?

Matveev, *Open problems and questions about geodesics*, §6.1, Question 6.1.1. Its mathematical question is:

The source explains that the flow is ergodic on the invariant set of geodesics meeting the negative-curvature locus. Its complement consists of vectors \(v\) such that

\[K(\gamma_v(t))=0\qquad\text{for every }t\in\mathbb R. \]

It asks whether this complementary set has Liouville measure zero. It also records the analogous higher-dimensional rank-one question, warns that several 1980s claims of a solution used an incorrect proof that the higher-rank set has measure zero, and distinguishes Liouville measure from Knieper's unique measure of maximal entropy.

Zero curvature geodesics and flat strips. Comparison with the original PDF shows that §6.2 starts there. It is not part of Question 6.1.1.

07243 | AIM-GEOMETRY-0004

Fixed-volume degeneration of Maxwell cavity eigenvalues

P / partially_solved | AIM 研讨会问题汇编

The AIM problem asks about the first three eigenvalues of the perfectly conducting electric cavity problem \[\operatorname{curl}\operatorname{curl}E=\lambda E, \qquad \operatorname{div}E=0\quad\hbox{in }\Omega, \qquad E\times\nu=0\quad\hbox{on }\partial\Omega, \] and asks which shapes optimize \(\lambda_k(\Omega)\), for \(k=1,2,3\), under a volume constraint, either without or with convexity. It asks in particular whether the ball should be expected to be optimal.

There are three necessary repairs to the wording.

1. A nonempty domain is open and therefore is not compact. Here “smooth compact domain” is read as a bounded connected open set with compact closure and smooth boundary. 2. The last displayed constraint on the AIM page says “in \(\partial\Omega\)”; it must read “on \(\partial\Omega\).” 3. The displayed \(C^1\) Rayleigh quotient is only formal. Its natural completion is a subspace of \(H_0(\operatorname{curl};\Omega)\cap H(\operatorname{div};\Omega)\). Also, zero-frequency harmonic fields have to be removed or excluded by a topological hypothesis before the positive eigenvalues can be numbered unambiguously.

The strongest result below concerns the standard convex Lipschitz relaxation of the question. Cuboids are not smooth, so the distinction from the literal smooth class is recorded rather than hidden.

07255 | AIM-GEOMETRY-0354

Form Q-operators: recovered status and a two-gate cohomology descent criterion

P / partially_solved | AIM 研讨会问题汇编

The official HTML transcription and the source PDF resolve several important ambiguities.

The opening sentence, “Problem 2 have a role to play in the problem of characterising the \(Q\)-curvature and the GJMS operators,” is the tail of the preceding item and is not part of the present problem. The heading “A generalisation: maps like \(Q\)” begins an expository construction. The displayed item labelled Exercise 7 is genuinely an exercise. The statement about \(S^p\times S^q\) is explicitly labelled a fact, not a question. Only the final sentence is the open-ended prompt:

The official recompiled HTML labels this “Problem 35: Generalizations of \(Q\).” It is a research program rather than a single proposition with a yes-or-no answer.

Let \(M\) be compact, oriented, without boundary, not necessarily connected, and of even dimension \(n\). Write \[\mathcal E^k=\Omega^k(M),\qquad \mathcal C^k=\ker(d:\Omega^k\longrightarrow\Omega^{k+1}). \] Weighted forms are denoted \(\mathcal E^k[w]\). Orientation and the conformal Hodge operator identify the appropriate dual weighted \(k\)-form bundle with \((n-k)\)-forms. The kernel and range of an operator are denoted \(\mathcal N(\cdot)\) and \(\mathcal R(\cdot)\).

The record first views ordinary \(Q\)-curvature as multiplication \[Q^g:\mathcal C^0\longrightarrow\mathcal E^n, \] where \(\mathcal C^0\) consists of functions constant on each connected component. Its five listed properties are:

1. \(\widehat Q=Q+P_n\omega\) for \(\widehat g=e^{2\omega}g\), with \(P_n=dMd\) formally self-adjoint. 2. \(Q:\mathcal C^0\to H^n(M)\) is conformally invariant. 3. If \(c\in\mathcal C^0\) and \(u\in\ker P_n\), then \(\int_MuQc\) is conformally invariant. 4. Multiplication by \(Q\), viewed as \(\mathcal E^0\to\mathcal E[-n]\), is formally self-adjoint. 5. \(Q1\) is \(Q\)-curvature.

The middle-degree model in the clean source is \[M^g=d\delta+2J-4\mathsf P^\sharp: \mathcal E^{n/2-1}\longrightarrow\mathcal E^{n/2-1}[-2], \tag{35} \] where \(\delta\) is the metric codifferential, \(\mathsf P\) is the Schouten tensor acting as an endomorphism of forms, and \(J=\operatorname{tr}\mathsf P\). The target is conformally identified with \(\mathcal E^{n/2+1}\). Exercise 7 asks for the transformation law on closed forms \[M^{\widehat g}=M^g+\beta\,\delta d\,\omega , \] where \(\omega\) acts by multiplication and \(\beta\ne0\) depends on conventions. The induced detour operator \[\delta M^g d:\mathcal E^{n/2-2}\longrightarrow \mathcal E^{n/2-2}[-4] \] is conformally invariant; in dimension four it is the Paneitz operator, up to normalization and sign conventions.

The general construction asserted in the record consists of operators \[M_k^g:\mathcal E^k\longrightarrow\mathcal E^{n-k}, \qquad 0\le k\le n/2-1, \] with:

- on \(c\in\mathcal C^k\), \[M_k^{\widehat g}c=M_k^gc+L_k^g(\omega c), \qquad L_k^g\ \text{formally self-adjoint}; \] - \(L_k^g\) is a nonzero constant multiple of \(dM_{k+1}^gd\), in the complementary-degree realization; - \(\mathcal H_g^k:=\ker(dM_k^g:\mathcal C^k\to\mathcal E^{n-k+1})\) is conformally invariant and \[M_k:\mathcal H^k\longrightarrow H^{n-k}(M) \] is conformally invariant; - \(\int_M\langle u,M_k^gc\rangle\) is conformally invariant for \(c\) closed and \(u\in\ker L_k\); - \(M_k^g\) is formally self-adjoint; - the clean source says \(M_0^g1\) is \(Q\)-curvature. The OCR string “\(M^g>0\,1\)” is corrupt.

In the weighted-form presentation used in the literature, codifferentials occur on the left, for example \(L_k=\delta Q_{k+1}d\). After the conformal Hodge identification with complementary-degree true forms, the left \(\delta\) becomes, up to conventional sign, an exterior \(d\). These are two presentations of the same structure and must not be mixed in one formula.

Freeze-Tag: Optimal Strategies for Awakening a Swarm of Robots

S / solved | AMR 问题清单汇编

An optimization problem that naturally arises in the study of ``swarm robotics'' is to wake up a set of ``asleep'' robots, starting with only one ``awake'' robot. One robot can only awaken another when they are in the same location. As soon as a robot is awake, it may assist in waking up other robots. The goal is to compute an optimal awakening schedule such that all robots are awake by time t^*, for the smallest possible value of t^* (the optimal makespan). The n robots are initially at n points of a metric space. The problem is equivalent to finding a spanning tree with maximum out-degree two that minimizes the radius from a fixed source. Is it NP-hard to determine an optimal awakening schedule for robots in the Euclidean (or L_1) plane? In more general metric spaces, can one obtain an approximation algorithm with better than $O(\log n)$ performance ratio?

General tractor Laplacians and their Einstein factorization

P / partially_solved | AIM 研讨会问题汇编

Problem 33. Give general formulae or inductive formulae for the operators \(\Box_{2\ell}\).

Its exact `problem` field begins

and then records the affine transformation law labelled (43).

The sentence beginning “In another direction” starts the discussion leading to Problem 34 and is not part of Problem 33.

The preceding source context is essential. On a conformal \(n\)-manifold the operators \(\Box_{2\ell}\) are conformally invariant, even-order, tractor-coupled analogues of the GJMS operators. They arise by applying powers of the ambient Laplacian to homogeneous ambient tensor fields corresponding to tractors. In even dimension, the particular operator \(\Box_{n-2}\) on the weighted standard tractor bundle has leading part \(\Delta^{n/2-1}\) and obeys \[\Box_{n-2}I^g=(0,0,Q_n^g)^T, \qquad \Box_{n-2}D\omega=(0,0,P_n^g\omega)^T. \] Thus a formula for the full tractor operator gives a route to critical \(Q\)-curvature and the critical GJMS operator.

07274 | AIM-GEOMETRY-0401

Generating families, augmentations, and the missing quantifiers

P / partially_solved | AIM 研讨会问题汇编

(a) Is Linearized Contact Homology always equal to Generating Function Homology [definition?] for a (compact?) Legendrian \(L\subset J^1(\mathbb R^n)\)? As evidence for this conjecture, it was proved in the case where \(L\) is the double of a compact \(n\)-manifold with boundary \(M\subset\mathbb R^n\).

(b) For a Legendrian \(L\subset\mathbb R^n\), does \(L\) admit a generating function [satisfying what restrictions?] if / only if the Linearized Contact Homology of \(L\) is (uniquely) defined?

The official AIM PDF uses the convention \[J^1(M)=\mathbb R_u\times T^*M, \qquad \alpha=du-p\,dq, \] which is the usual \(T^*M\times\mathbb R_z\) with contact form \(dz-p\,dq\), up to the order and name of the coordinates. It prints Question 1.4 as follows (typographical line-break hyphens suppressed, but the tentative brackets preserved):

Literally, however, that phrase does not specify a contact structure or the appropriate Legendrian dimension. The surrounding definition and part (a) strongly suggest the intended ambient space was \(J^1(\mathbb R^n)\). All mathematical conclusions below explicitly state their ambient space.

The appended “Theme 1.5” begins on the next page and expressly says that it is not asking a question. It is neighboring workshop context, not part of Question 1.4.

07352 | AIM-GEOMETRY-0324

Global balancing as a recognition obstruction

P / partially_solved | AIM 研讨会问题汇编

Given such a homogeneous, value-group-rational, totally concave polyhedral complex, what further conditions are necessary for it to be the amoeba of a prime Laurent ideal?

The AIM PDF and HTML recover this as follows. Let \(k\) be an algebraically closed non-archimedean field and let \[\mathfrak p\subset k[x_1^{\pm1},\ldots,x_d^{\pm1}] \] be prime. Its non-archimedean amoeba agrees with the Bieri--Groves set of \[A=k[x_1^{\pm1},\ldots,x_d^{\pm1}]/\mathfrak p. \] The source says that this set is a “homogeneous polyhedral complex,” has dimension \(\dim A\), is rational over the value group, and is totally concave. It asks:

The historical terminology matters. Bieri and Groves define a polyhedron to be homogeneous when it admits a finite decomposition into convex polyhedra all having the dimension of the whole set. Thus “homogeneous” means pure-dimensional here, not invariant under scaling and not “homogeneous ideal.” Their total concavity condition says that at every \(u\) the convex hull of the local cone \(LC_u(S)\) is an affine subspace. Gubler later uses exactly this local-cone formulation.

07353 | AIM-GEOMETRY-0351

Global conformal invariants and the four-dimensional Q-Pfaffian bridge

S / solved | AIM 研讨会问题汇编

Conjecture 3. Any \(S\) as above may be written \[\mathrm{const}\cdot\mathrm{Pff}+L+V, \] where \(V\) is an exact divergence.

If \(S\) is a natural \(n\)-form and \(\int S\) is conformally invariant, then ...

Recovered Conjecture 3. Let \(M^n\) be a closed oriented Riemannian manifold of even dimension. If \(S(g)\) is a natural metric \(n\)-form whose integral is unchanged by every conformal rescaling \(\widehat g=e^{2\omega}g\), then \[S(g)=c\,\operatorname{Pff}(g)+L(g)+d\beta(g), \] where \(L\) is a local conformal invariant \(n\)-form and \(\beta\) is a natural \((n-1)\)-form.

The missing phrase “\(S\) as above” is recovered from Conjecture 1 on the preceding page of the AIM source:

The surrounding chapter assumes an oriented Riemannian manifold of even dimension \(n\), regards scalar densities as \(n\)-forms, and suppresses some density weights. For the global assertion and for an exact divergence to integrate to zero without boundary terms, the standard hypothesis is that \(M^n\) is closed. Thus the intended conjecture is:

For comparison with Alexakis, write \(S(g)=P(g)dV_g\). The precise Deser-Schwimmer class consists of scalar Riemannian invariants \(P(g)\) that are finite linear combinations of complete contractions of covariant derivatives of the Riemann tensor and have constant-rescaling weight \(-n\).

Only the displayed Conjecture 3 is the assigned conjecture. The subsequent \(\mathcal P\)- and \(\mathcal L\)-filtrations, Exercise 6, and the tractor construction of \(Q\) are explanatory material and further questions, not additional clauses of Conjecture 3.

Globality, Lee-cover volume, and mapping-torus resonance for lcs forms

P / partially_solved | AIM 研讨会问题汇编

Question 1.36. Given a c.s.s. is it global?

There is the following result: a c.s.s. \(\Omega\) is global if and only if \(\omega\) is exact. Are there other conditions?

Banyaga has constructed c.s.s. for which \(\Omega\) is non zero in the Lichnerowicz cohomology, but such examples seem few and far between.

The acronym `c.s.s.` is the notes' abbreviation for a “(local) conformal symplectic structure”; the standard modern term and abbreviation are **locally conformally symplectic (lcs)**. The immediately preceding source text fixes the convention \[d\Omega=-\omega\wedge\Omega, \qquad d_\omega=d+\omega\wedge, \qquad d_\omega\Omega=0, \] where \(\omega\) is a closed Lee form. To avoid confusing the Lee form with a symplectic form, this report renames it \(\theta\).

With this sign convention, if \(\theta=dh\), then \[d(e^h\Omega)=e^h(dh\wedge\Omega+d\Omega)=0. \] Thus the global symplectic representative is \(e^h\Omega\). Conversely, if \(\Omega=f\sigma\), where \(f>0\) and \(d\sigma=0\), then \(\theta=-d\log f\). This verifies the sign in the source's “if and only if” rather than silently importing the opposite convention common in some papers.

O / open | Oberwolfach 报告问题汇编

For every c, does there exist a locally finite convex-cell partition of $\mathbb{R}^3$ in which every cell meets at least c vertices and every vertex meets at least c cells? Separately, for a finite set $S\subset\mathbb{R}^d$, let $\operatorname{MEE}(S)$ be its minimum enclosing ellipsoid, let DBM be the Banach-Mazur distance, and define $f(d,\varepsilon)$ as the supremum over S of the minimum cardinality of $X\subseteq S$ satisfying $\operatorname{DBM}(\operatorname{MEE}(X),\operatorname{MEE}(S))\leq\varepsilon$. Is $f(d,\varepsilon)=O(d/\varepsilon^2)$?

High-dimensional Gaussian energy and a tensor-product obstruction

P / partially_solved | AIM 研讨会问题汇编

Behavior of energy as $n \rightarrow \infty$ with α fixed. (Gaussian core model). Known for small α by the paper of Cohn and de Courcy-Ireland.

This one-line record does not specify the energy normalization, the particle density, or whether competitors are restricted to lattices. The cited primary paper makes the intended problem precise [CDI18]. Its setup is as follows. For \[f_\alpha(r)=e^{-\alpha r^2},\qquad \alpha>0, \] and a discrete set $\mathcal C\subset\mathbb R^n$ of density $\rho>0$, meaning \[\#(\mathcal C\cap B_R)=\bigl(\rho+o(1)\bigr)\operatorname{vol}(B_R), \] the lower energy is \[\underline E_\alpha(\mathcal C) =\liminf_{R\to\infty} \frac{1}{\#(\mathcal C\cap B_R)} \sum_{\substack{x,y\in\mathcal C\cap B_R\\x\ne y}} e^{-\alpha\lVert x-y\rVert^2}. \tag{1} \] The sum counts ordered pairs. Thus this is energy per particle without the physical convention of dividing pair energy by two. The quantity under study is \[M_n(\alpha,\rho) =\inf\bigl\{\underline E_\alpha(\mathcal C): \mathcal C\subset\mathbb R^n\text{ discrete of density }\rho\bigr\}. \tag{2} \] Competitors are arbitrary configurations, not merely lattices or periodic sets.

For a lattice Λ of density $\rho=1/\operatorname{covol}(\Lambda)$, the limit exists and \[E_\alpha(\Lambda) =\sum_{x\in\Lambda\setminus\{0\}}e^{-\alpha\lVert x\rVert^2} =\Theta_\Lambda(\alpha i/\pi)-1. \tag{3} \] All results below use exactly this reconstruction. A different convention with unordered pairs would multiply every energy by $1/2$.

07392 | AIM-GEOMETRY-0389

Higher-even-dimensional Polyakov formulae

P / partially_solved | AIM 研讨会问题汇编

Problem 29: 3 Is (40) true in higher even dimensions? The following conjecture would be enough to answer the previous problem.

This record cannot be read in isolation. With \(\widehat g=e^{2\omega}g\), the recovered display is \[-\log\frac{\det \widehat A}{\det A} =\alpha\left\{\frac12\int_M\omega P_g\omega\,dv_g +\int_M\omega Q_g\,dv_g\right\} +\left(\int_M F_{\widehat g}\,dv_{\widehat g} -\int_M F_g\,dv_g\right)+\mathcal H . \tag{40} \] Here \(A\) is a natural differential operator with positive-definite leading symbol, described as a positive power of a conformally invariant operator; the source gives a GJMS operator and the square of the Dirac operator as examples. It says that (40) is known in dimensions \(2,4,6\), that \(F\) is a local scalar invariant, and that \(\mathcal H\) depends on the nullspace of \(A\). The determinant is zeta regularized.

Two repairs are necessary for mathematical well-posedness.

1. If \(\ker A\ne0\), the displayed determinant must be read as the reduced determinant \(\det' A\) over the nonzero spectrum (or as an equivalent determinant-line norm). Otherwise the determinant vanishes and its logarithm is undefined. This is precisely the regime for which \(\mathcal H\) is present. 2. “Positive power” has at least two meanings. A literal spectral power \(B^r\) is different from a natural conformal power such as a GJMS operator with leading term \(\Delta^r\). Conformal covariance between weighted bundles does not in general survive naive composition after a metric trivialization. The results below keep these meanings separate.

The problem is therefore recovered as follows: **on a closed manifold of even dimension \(n\ge8\), under what hypotheses does the finite conformal variation of a zeta determinant have the form (40)?**

Idempotent geometry and the ideal--congruence divide

P / partially_solved | AIM 研讨会问题汇编

The record is item A.12, “Idempotent geometry,” contributed by G. L. Litvinov in cooperation with G. B. Shpiz to the AIM workshop list *Amoebas and tropical geometry*. The source asks a six-part foundational program:

1. Can algebraic geometry be constructed over a class of algebraically closed idempotent semifields, beyond only tropical semifields? 2. Can one define abstract, rather than only affine or projective, varieties over tropical and idempotent semifields? 3. Can regular functions and regular maps be defined so as to obtain a natural category of affine varieties and a correspondence with idempotent semirings of functions? 4. Can equations and ideals be defined so that points and subvarieties correspond to suitable analogues of ideals? 5. What should prime ideals, irreducible varieties, and decomposition into irreducible components mean? 6. Can dequantization produce a natural correspondence, perhaps a functor or “almost functor,” from traditional algebraic varieties to tropical varieties?

This is a recovered statement, not a single yes/no theorem. The isolated “8” is the PDF page number, not mathematics.

07434 | AIM-GEOMETRY-0216

Integral divisibility profiles and a gcd obstruction for minimax levels

P / partially_solved | AIM 研讨会问题汇编

Question 3.2.1 (Hingston). Does there exist a metric on S^n and a class $X\in H_*(\Lambda S^n;\mathbb Z)$ such that $$ 0<\operatorname{cr}_{\mathbb Z}(mX) <\operatorname{cr}_{\mathbb Z}(X) $$ for some $m\in\mathbb N$? In the simplest case, can one find a metric on S^2 and $m\in\mathbb N$ with this strict inequality when X generates $H_1(\Lambda S^2;\mathbb Z)$?

It comes from Section 3.2, “Stability of minimax levels,” of Keith Burns and Vladimir S. Matveev, *Open problems and questions about geodesics*.

<https://aimath.org/pastworkshops/geodesicsproblems.pdf>.

The preceding paragraph in the PDF fixes a compact Riemannian (or Finsler) manifold M, writes ΛM for its free loop space, and sets $$ \Lambda^a M=\{\gamma\in\Lambda M:\operatorname{Length}(\gamma)\leq a\}. $$ For $0\neq X\in H_*(\Lambda M;G)$, its critical level is $$ \operatorname{cr}_G(X) =\inf\{a:X\in\operatorname{im}(H_*(\Lambda^aM;G) \longrightarrow H_*(\Lambda M;G))\}. $$ Equivalently it is the infimum, over singular cycles representing X, of the largest loop length on the cycle.

The record then explains the coefficient question. For a coefficient field G, it writes the global mean frequency as $$ \alpha_{g,G} =\lim_{\deg X\to\infty}\frac{\deg X}{\operatorname{cr}_G(X)} \tag{3.1} $$ over nonzero $X\in H_*(\Lambda S^n;G)$, and cites the resonance theorem of Hingston--Rademacher for existence of the relevant asymptotic quantity on spheres. It observes that the nonzero integral homology groups of ΛS^n are $\mathbb Z$ or $\mathbb Z_2=\mathbb Z/2\mathbb Z$ (and are torsion-free for odd spheres), then specializes to $H_k(\Lambda S^n;\mathbb Z)=\mathbb Z X$. For $j,m\in\mathbb N$, $$ \operatorname{cr}_{\mathbb Z}(jmX) \leq\operatorname{cr}_{\mathbb Z}(mX) $$ because every filtered image is an additive subgroup.

Finally, to illustrate a possible coefficient effect, the source supposes that there are real numbers $a<b<c<d$ for which $$ \operatorname{cr}_{\mathbb Z}(mX)= \begin{cases} d,&\gcd(m,3)=\gcd(m,7)=1,\\ c,&3\mid m\text{ and }\gcd(m,7)=1,\\ b,&7\mid m\text{ and }\gcd(m,3)=1,\\ a,&21\mid m. \end{cases} \tag{1.1} $$

The source itself alternates between M and S^n; in the question $M=S^n$.

Kernel, cokernel, and a top-degree obstruction for contact Kirwan maps

P / partially_solved | AIM 研讨会问题汇编

Recovered Question 3.1 (E. Lerman). Let \[S^1\curvearrowright S^3\subset\mathbb C^2,\qquad \lambda\cdot(z_1,z_2)=(\lambda z_1,\lambda^{-1}z_2). \] The action is free, so \(H^*_{S^1}(S^3)\) is the ordinary cohomology of \(S^3/S^1\cong\mathbb P^1\). For the standard invariant contact form, the contact moment map is \[\mu(z_1,z_2)=|z_1|^2-|z_2|^2, \] and the contact quotient is \(\mu^{-1}(0)/S^1\cong S^1\). Thus the restriction map cannot be surjective. What are its kernel and cokernel?

Recovered Comment 3.2 (C. Boyer). Determine conditions under which a contact Kirwan surjectivity theorem might hold, possibly for a class of 3-Sasakian spaces and perhaps only through a dimension range.

07469 | AIM-GEOMETRY-0221

Known genuine examples and a contact-symplectic surface obstruction

S / solved | AIM 研讨会问题汇编

If \(\phi^t:SM\to SM\) is the geodesic flow, it asks whether there is a \(D\phi^t\)-invariant splitting \[T(SM)=E^s\oplus E^c\oplus E^u \] and constants \(C\geq 1\) and \(\lambda>\mu>0\) such that, for \(t\geq0\), \[\|D\phi^t\xi\|\leq Ce^{-\lambda t}\|\xi\|\quad(\xi\in E^s), \qquad \|D\phi^{-t}\eta\|\leq Ce^{-\lambda t}\|\eta\|\quad(\eta\in E^u), \tag{4.1} \] and, for every \(t\in\mathbb R\) and \(\zeta\in E^c\), \[C^{-1}e^{-\mu |t|}\|\zeta\| \leq \|D\phi^t\zeta\| \leq Ce^{\mu |t|}\|\zeta\|. \tag{4.2} \] The question is: **is there an example of a geodesic flow satisfying this condition?** The source then observes that an Anosov geodesic flow is a degenerate positive answer and says that genuine examples were constructed by Carneiro and Pujals.

1. The words beginning “5. Negative curvature and hyperbolicity…” and the marked-length-spectrum paragraph belong to the next section of the PDF, not to Question 4.1.4. They are excluded here. 2. The workshop list describes the Carneiro--Pujals starting metric as a “higher rank locally symmetric space.” Their primary paper instead starts with a **compact locally symmetric manifold of nonconstant negative sectional curvature** (hence a rank-one noncompact-type model). Indeed, the same paper proves that a compact locally symmetric space of nonpositive curvature whose geodesic flow is partially hyperbolic must already have an Anosov geodesic flow, and that any nonpositively curved partially hyperbolic example has rank one. Thus “higher rank” in the workshop sentence should not be used to describe their construction.

Throughout, “genuine” means partially hyperbolic but not Anosov, and the stable and unstable bundles are required to be nonzero. This convention is essential; see Section 8.

Recovered Question 7.2.1. Let \(M\) be a connected complete Riemannian manifold without conjugate points. If two nonconstant closed geodesics are freely homotopic, must their lengths be equal?

Matveev's problem list, contains the following question and then a transition paragraph:

Inspection of page 16 of the displayed journal pagination (page 15 of the PDF text indexing) confirms this wording. The singular phrase “no conjugate point” means the standard condition “without conjugate points.” The subsequent paragraph beginning “One can still hope for a version of the theorem...” is contextual prose. Its latter part introduces the Euclidean parallel-postulate problem that is separately labeled Question 7.2.2 in the source. It imposes no extra hypothesis on Question 7.2.1.

The natural meaning of “homotopic” here is **freely homotopic**: the closed curves need not have a common basepoint. This agrees with the source's use of the free loop space and with the later published formulation. A based-homotopy reading is a special case. The standard setting of Section 7 is a smooth complete Riemannian manifold without conjugate points; in particular, a closed manifold is included. The section introduction explicitly recalls that the universal cover is homeomorphic to Euclidean space and that any two of its points are joined by a unique geodesic.

Thus the recovered problem is:

The answer is yes. If “closed geodesic” is regarded as an unoriented geometric curve, the same answer holds when one loop is freely homotopic to the orientation reversal of the other.

Literal quotient is two-dimensional in the four-dimensional parity-even model

P / partially_solved | AIM 研讨会问题汇编

Problem 6: Is \(\mathcal L/(\mathcal L'+\mathcal L'')\) one-dimensional and generated by the class of \(Q\)?

The exact AIM record is:

The notation is recovered from the immediately preceding Problems 5a--5b and from Branson--Gover's workshop notes. On a closed even-dimensional Riemannian manifold, write a critical-weight local scalar invariant as the density \[\mathbf S_g=S_g\,dv_g. \] Problem 5b literally calls the space of such local invariants \(\mathcal L\). The subspace \(\mathcal L'\) consists of those \(\mathbf S\) having a **local conformal primitive**: there is a critical-weight local density \(\mathbf F\) such that, for every background metric and every \(\omega\), \[\left.\frac d{dt}\right|_{0}\int_M\mathbf F_{e^{2t\omega}g} =\int_M\omega\,\mathbf S_g. \tag{1} \] The space \(\mathcal L''\) consists of pointwise local conformal invariant densities. The source's displayed equation in Problem 5a suppresses the integral against \(\omega\); (1) is the unambiguous formula in the cited Branson--Gover notes.

There is a consequential ambiguity. The same workshop document later asks, in Problem 30, for the corresponding decomposition only for natural \(n\)-forms \(\mathbf S\) whose integrals are conformally invariant. Branson's precise invariant-theoretic treatment also uses the smaller formally-self-adjoint space \(\mathcal X_{\rm FSA}\). Thus this report treats separately:

1. the literal Problem 5b reading, where \(\mathcal L\) is the full critical-weight local-invariant space; and 2. the conformal-index/formally-self-adjoint reading that appears to be the intended conjecture.

All statements below concern densities, not bare scalars. The calculation is fixed-dimension, parity-even, polynomial invariant theory in dimension four. It does not silently assert a stable-dimensional or non-polynomial classification.

Local Middle-Dimensional Symplectic Nonsqueezing

O / open | Oberwolfach 报告问题汇编

Let P_k be orthogonal projection onto the standard $\mathbb R^{2k}\subset\mathbb R^{2n}$. Two local middle-dimensional nonsqueezing questions remain open. First, for every symplectomorphism $\phi:\mathbb R^{2n}\to\mathbb R^{2n}$ and every $x\in\mathbb R^{2n}$, is

$$\operatorname{vol}_{2k}\bigl(P_k\phi(B_r(x))\bigr)\geq\omega_{2k}r^{2k}$$

for all sufficiently small $r>0$? Second, if $\{\phi_t\}_{t\in[0,1]}$ is a smooth family of symplectomorphisms with ϕ_0 linear, is

$$\operatorname{vol}_{2k}\bigl(P_k\phi_t(B_1)\bigr)\geq\omega_{2k}$$

for all sufficiently small $t\geq0$?

来源字段：https://doi.org/10.4171/owr/2012/35

07508 | AIM-GEOMETRY-0390

Local primitives versus divergence terms

P / partially_solved | AIM 研讨会问题汇编

The following conjecture would be enough to answer the previous problem.

Problem 30: If S is a natural n-form and ∫ S is conformally invariant, then

S = const · Q + L + G,

where L is a local conformal invariant and G has a local conformal primitive. That is, there is a local invariant F for which the conformal variation of ∫ F is ∫ ωG.

Problem 29 asks whether a Polyakov-type determinant formula known in dimensions \(2,4,6\) holds in higher even dimensions. A footnote in the official PDF says explicitly that Problems 29--32 are conjectures. Thus Problem 30 is a conjectural assertion, not a question despite its label “Problem.”

The source uses boldface \(n\)-forms; equivalently one can use scalar densities. On an oriented manifold write

\[\mathbf S_g=S_g\,dv_g. \]

The intended meanings, reconstructed from Branson's source article, are:

- “natural” means a universal local Riemannian invariant of critical weight \(-n\), constructed from a finite jet of the metric; the source's invariant-theoretic discussion uses polynomial contractions of curvature and its covariant derivatives; - \(\mathbf L\) is pointwise conformally invariant: \(\mathbf L_{e^{2\omega}g}=\mathbf L_g\); - \(\mathbf G\) has a local conformal primitive if there is another natural local critical density \(\mathbf F\) such that, on a closed manifold, \[\left.\frac d{dt}\right|_{0}\int_M\mathbf F_{e^{2t\omega}g} =\int_M\omega\,\mathbf G_g \tag{1.1} \] for every smooth \(\omega\).

The adjective “local” in the last item is strong: \(\mathbf F\) must itself be a natural finite-jet expression. A reference-metric-dependent path integral on one conformal class does not by itself meet this requirement.

P / partially_solved | AIM 研讨会问题汇编

For a bounded convex planar domain \(\Omega\), let \(u_\Omega\) solve \[-\Delta u_\Omega=1\quad\text{in }\Omega, \qquad u_\Omega=0\quad\text{on }\partial\Omega. \] Determine \[C_*:=\sup\left\{\|\nabla u_\Omega\|_{L^\infty(\Omega)}: \Omega\subset\mathbb R^2\text{ convex},\ |\Omega|=1\right\}. \] Is a point where the maximal gradient is reached necessarily on a flat boundary part, in a quantitatively controlled sense?

\[\nu_\Omega=0\qquad\hbox{on }\partial\Omega, \]

This correction is verified directly against the paper on which the AIM entry is based, Hoskins--Steinerberger (2021), and against the subsequent papers of Huang (2025) and Burdzy--Ftouhi--Mariano (2025). Thus the intended problem is the following.

The normalization is natural. If \(t>0\), then \[u_{t\Omega}(x)=t^2u_\Omega(x/t),\qquad \|\nabla u_{t\Omega}\|_\infty=t\|\nabla u_\Omega\|_\infty, \qquad |t\Omega|^{1/2}=t|\Omega|^{1/2}. \] Hence \[J(\Omega):=\frac{\|\nabla u_\Omega\|_\infty}{|\Omega|^{1/2}} \] is scale invariant and \(C_*=\sup J(\Omega)\).

Metric comparison for filtered loop and path homology

P / partially_solved | AIM 研讨会问题汇编

Question 3.1.1 (Paternain). How do the sums of the Betti numbers for ΛT M and

Ω(T (p, q) grow as T → ∞? Does the growth depend on the metric?

It was shown by Gromov in [Gromov2001] that if M is simply connected there is a constant C such that sum of the Betti numbers of Λ CN is at least ∑Ni=0 bi(Λ).

The exact `problem` field supplied for this attempt is:

The original PDF and adjacent text were checked. Immediately before the question, the source defines $\Lambda^T M$ to be the free loops of length at most T and $\Omega^T(p,q)$ to be the paths from p to q of length at most T. Thus `ΛT M` and `Ω( T (p, q )` are damaged renderings of \[\Lambda^T M, \qquad \Omega^T(p,q). \] The PDF itself has a stray parenthesis in the second notation on the question line; the preceding definition verifies the intended expression.

Its mathematically verified reconstruction is \[\sum_{j\ge0} b_j(\Lambda^{CN}M) \;\ge\; \sum_{i=0}^{N}b_i(\Lambda M). \tag{1.1} \] Indeed, Gromov's stronger statement says that, for a closed simply connected M, every class in $H_i(\Lambda M)$ has a representative supported on loops of length at most Ci. Equivalently, $H_i(\Lambda^{CN}M)\to H_i(\Lambda M)$ is surjective for $i\le N$, which implies (1.1). This stronger formulation is reproduced with proof in Heistercamp's Appendix C [Hei]. The compactness/closedness assumption, suppressed on the question line, is required by the cited theorem and by the uniform metric comparison below.

Mixed Hodge structures and the Hochschild-zero link-homology slice for plabic graphs

P / partially_solved | AIM 研讨会问题汇编

In high levels of generality, varieties pick up a mixed Hodge structure (Lam-Speyer). When the cluster variety is adequately nice, the mixed Hodge structure has only two dimensions, and the point count polynomial corresponds to a certain polynomial, but not the HOMFLY-PT.

What is the relationship between the mixed Hodge structure on the cohomology of a cluster variety coming from a plabic graph and knot invariants (eg. the Khovanov-Rozansky homology)?

来源字段：http://aimpl.org/clusterbraid/1/

07577 | AIM-GEOMETRY-0322

Mixed-cell multiplicity and the real parity obstruction

P / partially_solved | AIM 研讨会问题汇编

For a connected compact component \(K\) of an intersection of amoebas, does the associated mixed Monge--Ampère mass equal the volume of the mixed cell corresponding to \(K\)? Are the roots in \(\operatorname{Log}^{-1}(K)\) in one-to-one correspondence with the roots of the binomial system attached to that cell, in a way preserving real roots?

This is Question A.2 from the AIM workshop list *Amoebas and tropical geometry* (January 2004), contributed by F. Bihan.

In particular, `Monge-Amp\` ere`, `Rullg˚ ard`, and `Log -1(K)` mean Monge--Ampère, Rullgård, and \(\operatorname{Log}^{-1}(K)\), respectively. With those repairs, the question is:

Here \[\operatorname{Log}(z_1,\ldots,z_n) =(\log|z_1|,\ldots,\log|z_n|). \]

There is an important correction to the background premise. Passare and Rullgård do not identify the local mixed Monge--Ampère mass with the root count of the one fixed, unrotated system. Their Theorem 5 identifies it with an **average** of root counts for independently phase-rotated systems. This distinction is central to both questions.

Newton subdivisions as combinatorial models for tropical hypersurfaces

P / partially_solved | AIM 研讨会问题汇编

We know that the Bergman complex of a variety (as defined in Chapter 9 of Sturmfels' book on “Solving systems of polynomial equations”), i.e. the tropical variety, is a polyhedral complex. For linear subspaces, the paper of Ardila and Klivans shows that this Bergman complex has a very nice combinatorial structure: a subdivision of it is the order complex of the lattice of flats of the associated matroid, a very well understood combinatorial object. (As a corollary we get the topology, etc.) Question: Can we find a similar combinatorial description for other classes of Bergman complexes? (contributed by Federico Ardila)

Nijenhuis Geometry and Integrable Systems - Problem 1

O / open | AMR 问题清单汇编

For the KdV system, this was reported to be done already in [veselov], though we did not find detailed formulas. The booklet [moser81] relates stationary solutions of the KdV to the solutions of the Neumann systems. Namely, it is shown that the potential energy of the Neumann system evaluated along the trajectory and suitably scaled is a solution of the KdV system. Moreover, the solutions of the KdV equations obtained by this method are related to potentials in the Hills-Schr\"odinger equation whose spectrum has finitely many bands. See also [DKN, p. 219, eqn (2.162), pp. 247, 248].

What is special in the potential generated by $V(t)= C(t)/m(t)$?

Nijenhuis Geometry and Integrable Systems - Problem 5

O / open | AMR 问题清单汇编

Which Nijenhuis operators admit (The answer is known near almost every points and follows from the local description of geodesically compatible pairs in [splitting2, splitting1]. The question is most interesting near singular points of the Nijenhuis operator.) at least one geodesically compatible metric g? Given L, describe all the metrics geodesically compatible with it. Under some additional assumptions (L has n different eigenvalues at generic points and g is Riemannian), the problem was solved in [Matveev2006]. The case of metrics of non-Riemannian signatures, even in dimension 2, is still open. The Riemannian case is solved in [BMF], and the description of 2-dimensional geodesically compatible pairs such that g has signature $(+,-)$ near regular points is in [BMP,japan].

No conjugate points: flat-growth rigidity and the three-dimensional residue

P / partially_solved | AIM 研讨会问题汇编

Question 4.1.2. If \((M,g)\) has no conjugate points, does \(M\) carry a metric with nonpositive sectional curvature?

Matveev's problem list *Open problems and questions about geodesics*. Its text is:

The record continues by saying that uniformisation gives an affirmative answer in dimension two, that the problem is open even in dimension three, and that Croke--Schroeder, Lebedeva, and Ivanov--Kapovitch establish similarities between fundamental groups in the no-conjugate-points and nonpositively curved settings.

The surrounding section discusses **compact** manifolds, and every cited group-theoretic theorem relevant to the question is stated for compact manifolds. Accordingly, throughout this report:

* \(M\) is a connected, closed, smooth manifold of positive dimension; * \(g\) is a complete Riemannian metric without conjugate points; and * the requested nonpositively curved metric is allowed to differ from \(g\).

This closedness convention is substantive, not cosmetic. Lebedeva's rigidity theorem and the comparison between group growth and volume growth both use compactness.

There is a source-version discrepancy. A later short version of the list says that uniformisation and geometrisation make the answer affirmative in dimensions two and three. No proof or citation accompanies that stronger sentence. By contrast, Ivanov--Kapovitch's primary paper explicitly leaves the no-conjugate-points question open in dimension three and isolates a graph-manifold test case. Searches through 8 August 2026 did not locate a primary source resolving that remaining case. I therefore retain the conservative status “open,” including in dimension three.

The PDF writes “non positive”; below this is silently standardised to “nonpositive.” No mathematical symbols in the question required reconstruction.

One-dimensional radial power kernels and an Ehrhard Gaussian obstruction

P / partially_solved | AIM 研讨会问题汇编

If \(F:\mathbb R\to\mathbb R\) is even and convex, then for any \(f,g\in L^1(\mathbb R^n)\), \[\iint F(x\cdot y)f(x)g(y)\,dx\,dy \geq \iint F(x\cdot y)f^*(x)g^*(y)\,dx\,dy, \] and asks whether convexity of \(F\) can be weakened and whether there is a Gaussian version.

There is a minor transcription error in the displayed domain (one occurrence of `R^n` lacks the LaTeX backslash), but there is also a major mathematical omission. Xi--Zhao's actual Theorem 1.2 assumes that \(f\) and \(g\) are **nonnegative, quasi-concave, and integrable**, not arbitrary members of \(L^1\). Their theorem says that, for such \(f,g:\mathbb R^n\to[0,\infty)\) and every finite even convex \(F:\mathbb R\to\mathbb R\), \[\mathcal E_F(f,g):=\int_{\mathbb R^n}\int_{\mathbb R^n} F(x\cdot y)f(x)g(y)\,dx\,dy \geq \mathcal E_F(f^*,g^*). \tag{1} \] For strictly convex \(F\), their equality statement describes almost all superlevel-set closures of \(f\) and \(g\) as dilates of a common pair of polar-reciprocal origin-symmetric ellipsoids.

The qualification matters. Symmetric decreasing rearrangement is canonically defined here for nonnegative functions; for signed functions, writing \(f^*\) without specifying whether one rearranges \(|f|\), positive and negative parts, or a signed distribution is ambiguous. If one adopts the common convention \(f^*=(|f|)^*\), even the constant kernel \(F=1\) fails for \(f=-\mathbf1_{[0,1]}\), \(g=\mathbf1_{[0,1]}\): the two sides are \(-1\) and \(+1\). Quasi-concavity is also structural in Xi--Zhao: it makes the positive superlevel sets convex, allowing their convex-body symmetrization argument. The AIM workshop report states the indicator-function version for convex sets, consistent with this scope.

There is a second formulation issue: \(L^1\) alone does not make the displayed energies finite when \(F\) grows. A safe extended-real reading of (1) is obtained by setting \[\Phi(t)=F(t)-F(0)\geq0, \qquad \mathcal E_F(f,g)=F(0)\|f\|_1\|g\|_1+ \iint \Phi(x\cdot y)f(x)g(y)\,dx\,dy. \tag{2} \] The last integral is defined by Tonelli in \([0,\infty]\), so there is no \(\infty-\infty\) ambiguity. Since rearrangement preserves both masses, the constant term cancels. For a non-vacuous finite-energy assertion one should additionally assume either side, or preferably both sides, finite. For example, \(F(t)=t^2\) and an integrable quasi-concave function with an infinite second moment already produce an infinite energy in dimension one.

Open Problems and Questions about Geodesics - Conjecture 12 (Klingenberg)

O / open | AMR 问题清单汇编

The class of compact manifolds that support metrics with variable negative curvature is much larger than the class that support hyperbolic metrics (of constant negative curvature). The earliest examples of manifolds that support variable but not constant negative curvature were given by Mostow-Siu [Mos-Siu1980] and Gromov-Thurston [Gro-Thu1987]. Recent work of Ontaneda has vastly increased the supply of examples [Ontaneda2011, Ontaneda2014].

If a closed manifold admits a metric with Anosov geodesic flow, then it admits a metric with negative sectional curvature.

07660 | AMR-149-0019

Open Problems and Questions about Geodesics - Conjecture 19 ([Katok1982])

O / open | AMR 问题清单汇编

Katok [Katok1982] showed that if g is an arbitrary metric and g_0 a metric of constant negative curvature on a surface of genus ≥ 2 such that $\text{area}(g) = \text{area}(g_0)$, then $$ h_{Liou}(g) \leq h_{Liou}(g_0) =h_{top}(g_0) \leq h_{top}(g) $$ and both inequalities are strict unless g also has constant negative curvature. He explicitly formulated the following influential and still open conjecture:

$h_{top} = h_{Liou}$ for a metric of negative curvature on a compact manifold if and only if it is locally symmetric.

07661 | AMR-149-0002

Open Problems and Questions about Geodesics - Conjecture 2 (Long)

O / open | AMR 问题清单汇编

There exist results supporting this conjecture. In particular, H. Hofer, K. Wysocki and E. Zehnder in [Ho-Wy-Ze2003] studied Reeb orbits on contact S^3. Their result can be projected down to S^2, and implies that the total number of distinct prime closed geodesics for a bumpy Finsler metric on S^2 is either 2 or infinite, provided the stable and unstable manifolds of every hyperbolic closed geodesics intersect transversally. See also [Har-Pat2008,Rademacher2016].

The closed geodesics in Katok's example are elliptic.

The existence of one hyperbolic prime closed geodesic on a Finsler S^2 implies the existence of infinitely many distinct prime closed geodesics.

Open Problems and Questions about Geodesics - Problem 40

O / open | AMR 问题清单汇编

Flag curvature is the Finslerian analogue of sectional curvature. It was shown in [Akbar-Zadeh1988] that: any closed Finsler surface with constant flag curvature zero is locally Minkowskian; any sufficiently smooth closed Finsler surface with constant negative curvature is Riemannian (there are non-Riemannian examples which are not sufficiently smooth); and any connected closed Finsler surface with constant positive flag curvature is homeomorphic to S^2 or $\mathbb{R} P^2$. The result for negative flag curvature also follows from [Foulon1997] and is true in all dimensions.

Describe Finsler metrics on S^2 of flag curvature 1.

Open Problems and Questions about Geodesics - Question 13

O / open | AMR 问题清单汇编

Several examples of manifolds that admit metrics of non-positive curvature but cannot support a metric of negative curvature (or with Anosov geodesic flow) can be found in the introduction to [Ba-Br-Eb1985]. These examples have a copy of ${\mathbb{Z}} \times {\mathbb{Z}}$ in their fundamental group. The simplest of them is due to Heintze who took two cusped hyperbolic 3-manifolds, cut off the cusps, glued the two pieces together along their boundary tori and then smoothed out the metric to obtain a manifold with non-positive curvature.

If (M,g) has no conjugate points, does M carry a metric with non-positive sectional curvature?

Open Problems and Questions about Geodesics - Question 5 (Bangert)

O / open | AMR 问题清单汇编

Questions of this nature are also interesting in the realm of Finsler geometry. One would expect the results for reversible Finsler metrics to be very similar to those for Riemannian metrics. For irreversible Finsler metrics, Katok's example shows that there are compact Finsler manifolds with only finitely many closed geodesics, but it is still possible that all non-compact Finsler manifolds with finite volume might have infinitely many closed geodesics. On the other hand, the following question is completely open:

{\it Does there exist an irreversible Finsler metric of finite volume on $\mathbb{R}\times S^1$ with no closed geodesics?}

07705 | AMR-149-0051

Open Problems and Questions about Geodesics - Question 52

O / open | AMR 问题清单汇编

To the best of our knowledge, the existence of a closed geodesic on a Lorentzian manifold is a quite complicated problem and nothing is known in dimensions ≥ 3. In dimension 2, a closed orientable manifold with a metric of signature $(+,-)$ is homeomorphic to the torus. By [Suhr2013a], every Lorentzian 2-dimensional torus has at least two simple closed geodesics one of which is definite, i.e. timelike or spacelike. Moreover, explicit examples show the optimality of this claim.

We therefore ask the following

Does every closed Lorentzian manifold have at least one closed geodesic?

Open Problems and Questions about Geodesics - Question 68

O / open | AMR 问题清单汇编

There exist local (the first examples are due already to Lagrange, Beltrami and Dini) and global examples of non-proportional projectively equivalent metrics. Locally, in the Riemannian case, a complete description of projectively equivalent metrics is due to Levi-Civita [Levi-Civita1896] and in arbitrary signature is due to [Bol-Mat2015]. Globally, in the Riemannian case, the situation is also pretty clear, see e.g.\ [Mat-Top1998,Matveev2003a,Matveev2003b], but if the metrics have arbitrary signature, virtually nothing is known. A general problem is to understand the topology of closed manifolds admitting non-proportional projectively equivalent metrics of indefinite signature and as the simplest version of this problem we suggest

Can a 3-dimensional sphere admit two non-proportional projectively equivalent metrics of Lorentzian signature?

Open-book chord dictionaries and a binding-intersection filtration

P / partially_solved | AIM 研讨会问题汇编

There was a fair bit of discussion on how to possibly compute contact homology in terms of (contact) open books. For example, Denis Auroux pointed out that if you have a Lagrangian \(L\) in a page, then this is a Legendrian in the open book, and the Reeb chords are the intersections of \(L\) with \(\phi^k(L)\), where \(\phi\) is the monodromy. This might be a starting point for computing the relative contact homology of \(L\), in the complement of the binding, in terms of things related to symplectic Floer homology of Lagrangians. There is then the problem of understanding what happens when one puts back the binding, but this might correspond to an “\(A_\infty\) deformation”.

Ordered boundary rigidity from quadratically spanning minimizing geodesics

P / partially_solved | AIM 研讨会问题汇编

Question 5.1.3 ([Michel1981]). What conditions on (M,N) and (g) imply boundary rigidity?

In the official PDF, the preceding paragraph defines the data. If (M) is a compact manifold with smooth boundary (N=\partial M), a Riemannian metric (g) determines \[d_g^\partial(p,q)=d_g(p,q),\qquad (p,q)\in N\times N. \] The question itself is:

It then notes three variants: placing an additional assumption on a competing metric (g'), asking for restrictions on the allowed metric class, and replacing Riemannian metrics by Finsler metrics.

Two source issues matter.

1. The official PDF, not merely the JSON extraction, says that another metric with the same data “must be isometric to (g').” This is tautological. The standard and logically coherent reconstruction is “must be isometric to (g),” with the boundary gauge made explicit: there must be a diffeomorphism \(\psi:M\to M\) satisfying \(\psi|_N=\mathrm{Id}\) and, in one consistent pullback convention, \(g'=\psi^*g\). This correction is a labeled reconstruction, not a silent alteration of the source. 2. Everything in the canonical record beginning with “5.2. The conjugacy problem” belongs to the next section and next problem. The expressions OCRed as `SM >1`, `φ1 >t`, and `Ck` concern that separate problem. They are not analyzed here.

Thus the precise reading used below is: find geometrically meaningful hypotheses under which equality of boundary distance functions determines (g) up to a boundary-fixing diffeomorphism.

Partitioning the Projective Plane

P / partially_solved | Open Problem Garden

Throughout this post, by projective plane we mean the set of all lines through the origin in $\mathbb{R}^3$.

Definition Say that a subset S of the projective plane is octahedral if all lines in S pass through the closure of two opposite faces of a regular octahedron centered at the origin.

Definition Say that a subset S of the projective plane is weakly octahedral if every set $S'\subseteq S$ such that $|S'|=3$ is octahedral.

Conjecture Suppose that the projective plane can be partitioned into four sets, say S_1,S_2,S_3 and S_4 such that each set S_i is weakly octahedral. Then each S_i is octahedral.

Playfair rigidity without focal points

P / partially_solved | AIM 研讨会问题汇编

Question 7.2.2 ([Bur-Kni1991]). Must a metric satisfying this version of the par-allel postulate be flat?

The question looks like a question in the synthetic geometry, but it is not, since we do not require a priori that the other axioms of the Euclidean geometry are fulfilled (for example the congruence axioms). 7.2.1. Higher rank rigidity.

Consider the plane \(\mathbb R^2\) with a complete Riemannian metric. Assume that for every geodesic and for every point not on the geodesic there exists precisely one nontrivial geodesic that passes through the point and does not intersect the geodesic. This assumption implies that the metric has no conjugate points.

07783 | AIM-GEOMETRY-0250

Positive entropy and the topology of smooth metrics

P / partially_solved | AIM 研讨会问题汇编

Question 8.4.1. Do the metrics with positive entropy form a dense subset of G?This question can be asked for any k. For k = 2 it was recently positively answered in all dimensions in [Contreras2010]; see also [Con-Pat2002]. For k = ∞

and dimension 2, it was answered positively in [Kni-Wei2002].

The missing definitions occur in §8.4 immediately before this record. Let \(M\) be a smooth closed manifold and let

\[\mathcal G=\operatorname{Met}^{\infty}(M) \]

be the set of all smooth Riemannian metrics on \(M\). For a finite integer \(k\), \(\mathcal G\) is given the topology induced by the \(C^k\)-norms of the coefficient matrices \(g_{ij}\) in a finite atlas. The source explains that this topology is independent of the chosen finite atlas. The phrase “positive entropy” means

\[h_{\mathrm{top}}(\phi_g)>0, \]

where \(\phi_g^t:S_gM\to S_gM\) is the geodesic flow and entropy is the topological entropy of its time-one map. This interpretation is explicit in all three cited primary papers.

For \(k=\infty\), the correct standard interpretation on a compact manifold is the Whitney \(C^\infty\), equivalently Fréchet, topology on smooth sections of \(S^2T^*M\). It is generated by the seminorms \(\|\cdot\|_{C^r}\), \(r=0,1,\ldots\). A basic neighborhood controls only finitely many derivative orders; there is no single finite-valued “\(C^\infty\)-norm.”

The question concerns Riemannian metrics. Contreras discusses why analogous perturbation problems are more flexible for Finsler metrics, but his stated Theorem A and the space \(\mathcal G\) above are Riemannian. No Finsler conclusion is silently imported here.

Positive tropicalization, cluster fans, and a finite wall-detection criterion

P / partially_solved | AIM 研讨会问题汇编

Question. What is the connection between the tropicalization of the totally positive part of a variety and the cluster algebra structure of the variety?

Background. Speyer and Williams had described the tropicalization of the totally positive part of the Grassmannian \(G(k,n)\). For \(k=2\), the resulting fan is related to the type-\(A\) associahedron; for \(G(3,6)\) and \(G(3,7)\), the fans are related to the type-\(D_4\) and type-\(E_6\) associahedra. Scott had shown that the cluster algebra structures of \(G(2,n)\), \(G(3,6)\), and \(G(3,7)\) have the corresponding types.

07798 | AIM-GEOMETRY-0232

Prime closed geodesics with exponential error

P / partially_solved | AIM 研讨会问题汇编

The original AIM PDF was checked directly. Lines 564--580 give the missing context and the intact typeset display. Let (M,g) be a closed Riemannian manifold with negative sectional curvature, let $h=h_{\mathrm{top}}(\phi)$ be the topological entropy of its geodesic flow, and let $N(T)$ count closed geodesics of length at most T. The recovered conjecture is

\[N(T)=\left(1+O(e^{-\varepsilon T})\right) \int_2^{e^{hT}}\frac{du}{\log u} =\left(1+O(e^{-\varepsilon T})\right)\operatorname{Li}(e^{hT}) \tag{1} \]

for some $\varepsilon>0$.

The source does not explicitly say “primitive” or “oriented.” Its formula and the literature it invokes determine the natural convention:

* a **primitive** orbit traverses its image once and has least period $\ell(\gamma)$; * a periodic orbit of the geodesic flow is **oriented** by increasing flow time; * the Ruelle product and the prime-orbit theorem count primitive oriented periodic orbits.

Giulietti--Liverani--Pollicott explicitly use “oriented” in their prime-geodesic theorem. With that convention the leading coefficient in (1) is 1. Time reversal pairs the two orientations of each geometric geodesic, so the unoriented primitive count has leading term $\frac12\operatorname{Li}(e^{hT})$. Counting all iterates instead of only primitive orbits does not change the leading term, but it introduces an error of exact exponential scale $e^{hT/2}$; this is proved below. Thus the coherent recovery of N in (1) is the **primitive oriented** count.

Prime integral counterexamples to adelic halfspace intersection

S / solved | AIM 研讨会问题汇编

Let \(\mathfrak p\) be a prime ideal of \(R_d\) with \(\mathfrak p\cap\mathbb Z=\{0\}\), and let \(r=\dim_{\mathrm{Krull}}(R_d/\mathfrak p)\). For every subspace of \(\mathbb R^d\) of dimension \(d-r+1\), does every halfspace in that subspace intersect the adelic amoeba of \(\mathfrak p\)?

The AIM PDF and the exact HTML page confirm that the displayed ring is \[R_d=\mathbb Z[x_1^{\pm1},\ldots,x_d^{\pm1}]. The recovered statement is:

The published follow-up uses **rational open halfspaces** \[H=\partial H+\mathbb R_{>0}v, \] where \(\partial H\) is a rational linear subspace and \(v\notin\partial H\). This is the convention used below.

There is a dimension convention that must not be lost. Since \(\mathfrak p\cap\mathbb Z=0\), the generic fiber \[X=V(\mathfrak p\otimes_{\mathbb Z}\mathbb Q) \subset\mathbb G_{m,\mathbb Q}^{d} \] has \[\dim X=r-1. \] Thus the AIM number \(d-r+1\) is \(d-\dim X\), the complementary dimension used in the global-field formulation. Payne denotes \(\dim X\), not the dimension of the integral model, by \(r\).

07816 | AIM-GEOMETRY-0381

Q-curvature for Weyl structures and the Faraday ambiguity

S / solved | AIM 研讨会问题汇编

On an oriented conformal manifold of general even dimension, construct a natural invariant of a Weyl structure, preferably an \(n\)-form or weight-\(-n\) density, which reduces to Branson's Riemannian \(Q\)-curvature form when the Weyl connection is Levi-Civita. Determine what such an extension says about the choice of Riemannian \(Q\).

With its line breaks displayed, it reads:

The preceding text constructs, in dimension four, the invariant four-form \[\boldsymbol Q^{\rm ES}_{(g,\alpha)} = \left[Q_g-S_g^a\alpha_a +4\nabla^a\bigl(\alpha^b\nabla_{[a}\alpha_{b]}\bigr) \right]dv_g, \] which reduces to the Riemannian \(Q\)-curvature form \(Q_g\,dv_g\) when \(\alpha=0\). Problem 22 asks for an analogue on Weyl structures in all even dimensions.

The source corrections are:

- “Slov'ack” is Jan **Slovák**. - The attached “27” is a page/footer extraction marker, not part of the mathematical sentence; it is absent from the official HTML. - Boldface was lost. The four-dimensional contextual formula is \[\boxed{ \boldsymbol Q =2\boldsymbol P^2 -2\boldsymbol P^{ab}\boldsymbol P_{ba} -D^aD_a\boldsymbol P.} \] Here \(\boldsymbol P_{ab}\) is the Rho/Schouten tensor of the Weyl connection, \(\boldsymbol P=\boldsymbol P_a{}^a\), and \(D\) is the Weyl covariant derivative. The reversed contraction \(\boldsymbol P^{ab}\boldsymbol P_{ba}\) is intentional.

The original primer places Problem 22 before this boldface formula. It then says that the already constructed invariant is “not manifestly so” and rewrites it in the displayed form. Thus the formula is a four-dimensional answer/context immediately following the question, not an additional clause of the question. It also motivates Problem 23, which asks whether the detailed calculation was necessary.

The recovered problem is:

来源字段：https://aimath.org/WWN/confstruct/confstruct.pdf

07817 | AIM-GEOMETRY-0239

Quadratic counting of closed flat geodesic classes

P / partially_solved | AIM 研讨会问题汇编

Consider a closed surface of genus at least two with a metric of nonpositive curvature. Let \(N(T)\) be the number of free homotopy classes containing closed geodesics along which the Gaussian curvature is everywhere zero.

The PDF then asks: \[\lim_{T\to\infty}\frac{\log N(T)}{T}=0 \quad\Longrightarrow\quad N(T)\leq C T^2\ ? \] It attributes the question to Gerhard Knieper, says the answer is positive for the torus, and suggests a Finsler analogue.

The only coherent reconstruction is therefore \[N(T)=\#\{\text{eligible free homotopy classes whose geodesic length is at most }T\}. \] This reconstruction is also consistent with standard closed-geodesic counting notation and with the claimed torus case. In a nonpositively curved metric, all closed geodesics in one free homotopy class have the same length: their lifts are axes of one deck transformation, and the period is its translation length. Thus the threshold remains unambiguous when a class contains a whole flat cylinder.

The question ends with “One can also study this problem in the Finsler category.” The running header and everything from “7. In particular, Theorems 7.0.2 and 7.0.3 are not part of Question 6.5.1.

07823 | AIM-GEOMETRY-0328

Quantitative tropical-theta approximation on an affine circle

P / partially_solved | AIM 研讨会问题汇编

In particular, the affine transition group is \[\mathbb R^n\rtimes \operatorname{GL}_n(\mathbb Z), \] the singular set is $\Delta=B\setminus B_0$, the dual lattice is $\check\Lambda\subset \mathcal T^*_{B_0}$, and the equation is \[\det\left(\frac{\partial^2s_i}{\partial y_j\partial y_k}\right)=\text{constant}.

1. If B has an integral-affine structure on a dense open B_0, with $B\setminus B_0$ a locally finite union of locally closed submanifolds, should B be called a tropical Calabi--Yau variety, and are those singularities natural tropically? 2. With $\operatorname{Aff}(B,\mathbb R)$ the sheaf of continuous functions that are integral affine on B_0, a tropical line bundle is defined as a class in $H^1(B,\operatorname{Aff}(B,\mathbb R))$. If it is represented by a Cech cocycle (α_{ij}), a section is a family of tropical functions satisfying ordinary differences $s_i-s_j=\alpha_{ij}$. What are tropical Riemann--Roch, ampleness, very ampleness, and projective embeddings? 3. For the printed tropical cubic \[-6x^3-4x^2y-3xy^2-6y^3-4y^2z-3yz^2-0xyz-3x^2z-1xz^2-3z^3, \] the source asks the reader to check that its compact polygonal core has affine perimeter 13, and then asks for an embedding $\mathbb R/13\mathbb Z\to\mathbb{TP}^2$ by three sections of a degree-five line bundle. It asks whether contraction observed for a degree-three construction means that degree three is not very ample. Proposition 2 below finds a discrepancy: the exact printed coefficients give perimeter 15 under the standard projective lattice convention. 4. For the torus bundles $X(B_0)=\mathcal T_{B_0}/\Lambda$ and $\check X(B_0)=\mathcal T^*_{B_0}/\check\Lambda$, can smooth local potentials be found that solve the real Monge--Ampere equation? More specifically, can tropical sections $s_n\in\Gamma(B,\mathcal L^{\otimes n})$ be chosen so that $n^{-1}s_n$ converges to a classical solution, and can this be used numerically to visualize a Ricci-flat metric?

The HTML displays an index mismatch near the last question, writing $s_i\in\Gamma(B,\mathcal L^n)$ and then s_n. The sequence notation $s_n\in\Gamma(B,\mathcal L^{\otimes n})$ used above is an explicit reconstruction from the stated scaling $\hbar=1/n$.

Radial harmonic universality and linear-size zonotope approximation

P / partially_solved | AIM 研讨会问题汇编

Problem 3 (R. Gardner). Let \(\mathcal K^n\) be the convex bodies in \(\mathbb R^n\). A Minkowski class is closed in the Hausdorff metric and under Minkowski linear combinations and translations. A body \(K\) is a generalized \(\mathcal M\)-body if \(K+M_1=M_2\) for some \(M_1,M_2\in\mathcal M\). If \(\mathcal M_{B,G}\) is the smallest \(G\)-invariant Minkowski class containing \(B\), Schneider and F. Schuster's theorem says that, for nonsymmetric \(B\), every neighborhood of \(B\) contains an affine image \(B'\) of \(B\) for which the generalized \(\mathcal M_{B',SO(n)}\)-bodies are dense in \(\mathcal K^n\). The problem asks for a dual theorem, replacing generalized zonoids/Minkowski sums by generalized intersection bodies/radial sums.

Problem 4. If \(K\subset\mathbb R^n\) is a zonoid and \(Z\) is a zonotope that is a sum of \(M\) segments, Talagrand obtained \(M=C(\varepsilon)n\log n\) under multiplicative distance \(d(Z,K)\leq 1+\varepsilon\), while the Euclidean ball admits \(M=C(\varepsilon)n\). Is the extra \(\log n\) necessary?

07831 | AIM-GEOMETRY-0238

Radial zero curvature as a finite Jacobi-operator condition

P / partially_solved | AIM 研讨会问题汇编

Its boundaries matter.

1. The opening paragraph is a **remark continuing Question 6.2.1**, whose actual question occurs in the preceding canonical records. It asks what can be inferred, without assuming nonpositive curvature and possibly in higher dimensions, from either \[K_{\gamma(t)}(\sigma)=0\quad\text{for every two-plane }\sigma\subset T_{\gamma(t)}M, \] or the weaker radial condition \[K_{\gamma(t)}(\dot\gamma(t),v)=0\quad(v\perp\dot\gamma(t)). \tag{R} \] 2. Section 6.3 asks Eberlein's flat-closing question: if a compact rank-one manifold of nonpositive curvature contains an isometrically immersed Euclidean plane, must it contain a totally geodesically immersed flat torus? 3. Section 6.4 asks whether the Besson--Courtois--Gallot degree/volume-entropy rigidity theorem extends from negatively curved locally symmetric targets to higher-rank symmetric spaces of noncompact type. 4. The final two sentences merely begin Section 6.5 by defining \(N(T)\), the number of free homotopy classes containing zero-curvature closed geodesics. The actual Knieper question and its formula occur in the next canonical record, AIM-GEOMETRY-0239, and are not claimed here.

The input's garbled expression `h4 > vol Vol` is reconstructed from the original PDF and Merlin's paper as \[h_{\mathrm{vol}}(g)^4\operatorname{Vol}(M,g), \] the four-dimensional instance of the scale-invariant normalized volume entropy \(h_{\mathrm{vol}}(g)^n\operatorname{Vol}(M,g)\).

07834 | AIM-CONVEX_GEOMETRY-0021

Random central planes and approximate convexity

P / partially_solved | AIM 研讨会问题汇编

Conjecture. Let \(\mathcal K\) be the family consisting of the empty set and all compact convex subsets of \({\mathbb R}^n\) with nonempty interior. For compact \(S\subset{\mathbb R}^n\), choose \[C\in\operatorname*{arg\,min}_{D\in\mathcal K} |\Delta(S,D)|. \] Call \(S\) \(\varepsilon\)-convex when \[|\Delta(S,C)|\leq\varepsilon |S|. \] Assume that the center of gravity of \(S\) is the origin. Draw \(x,y\) independently and uniformly from \(S\), put \[H(x,y)=\operatorname{span}\{x,y\},\qquad P(x,y)=S\cap H(x,y), \] and let \(\mu\) be the resulting distribution of central two-dimensional sections. The conjecture is \[\Pr_\mu\{P(x,y)\text{ is convex}\}\geq1-\varepsilon \quad\Longrightarrow\quad S\text{ is }O(n\varepsilon)\text{-convex}. \tag{AIM} \]

The big-\(O\) means a universal constant. To make the sampling statement well-defined one must add \(n\geq2\), \(0<|S|<\infty\), and, as in the property-testing context, \(0<\varepsilon\leq1\). Compactness gives measurability and finite volume. Positive volume makes the uniform distribution and center of gravity meaningful. It also implies that \(x,y\) are nonzero and linearly independent almost surely, so \(H(x,y)\) is two-dimensional almost surely.

Rank-one meromorphic Hitchin duality and a marked-data obstruction

P / partially_solved | AIM 研讨会问题汇编

Langlands duality for meromorphic Higgs bundles

The existence of the hyperkahler metrics on the wild Hitchin spaces means the moduli spaces of meromorphic connection on curves (and the corresponding wild character varieties) have natural special Lagrangian torus fibrations, by hyperkahler rotation of the Hitchin fibration (shown to be proper in this generality by Nitsure).

Study the SYZ mirror symmetry proposal in this context. For example suppose we take the dual holomorphic Lagrangian fibration of the smooth fibres of the meromorphic Higgs bundle moduli space. Is the result another Hitchin fibration? What is the involution on the set of data (group, irregular curve, residue data) that corresponds to this T-duality?

For example for holomorphic Higgs bundles it is known one should just replace the group by the Langland dual group, so we are asking for an involution generalizing this.

The approach of Donagi-Pantev works for the Poisson moduli spaces of meromorphic Higgs bundles, so the question is about matching symplectic leaves.

Gukov-Witten studied the tame case and described interesting phenomenon related to rigid coadjoint orbits, but it does not seem that a precise involution was established

Conjecture 6.18 (Hausel--Rodriguez-Villegas). For a compact Riemann surface of genus g, coprime integers $(n,d)=1$, and $\zeta_n = \exp(2\pi i/n)$, let $$ \mathcal{M}_B^d(\mathrm{GL}_n) = \left\{(A_1, B_1, \ldots, A_g, B_g) \in \mathrm{GL}_n(\mathbb{C})^{2g} : \prod_{i=1}^g [A_i, B_i] = \zeta_n^d I_n\right\} \!\!/\!\!\, \mathrm{PGL}_n $$ be the twisted $\mathrm{GL}_n(\mathbb{C})$ character variety, with ordinary-cohomology mixed Hodge polynomial $H_n^{\mathrm{geom}}(x,y,t) = \sum_{p,q,k} h^{p,q;k}(\mathcal{M}_B^d(\mathrm{GL}_n)) x^p y^q t^k$, and let $\mathbb{H}_n(q,t)$ be the combinatorial rational function defined via the partition-hook plethystic product. Then $$ H_n^{\mathrm{geom}}(\sqrt{q}, \sqrt{q}, t) = \mathbb{H}_n(q, t). $$

Recovering the marking from a flow conjugacy

P / partially_solved | AIM 研讨会问题汇编

Conjecture 5.2.1. Compact Riemannian manifolds with negative curvature must be isometric if they have C0-conjugate geodesic flows. As with

As with Conjecture 5.1.1 it may be possible to relax the hypothesis of negative curvature to no conjugate points, but some restriction on the metrics is required. Weinstein pointed out that all of the Zoll metrics on \(S^2\) have conjugate geodesic flows. Using the explicit rotationally-symmetric examples of Zoll metrics (Tannery metrics in the terminology of [Besse1978, Chapter 4]) Croke and Kleiner constructed examples of different metrics on an arbitrary closed manifold such that their geodesic flows are conjugate and their marked length spectra coincide, see [Cro-Klei1994].

The conjecture is true in dimension two; indeed it is enough to assume that one of the manifolds has nonpositive curvature [Cr-Fa-Fe1992]. It follows from the theorem of Besson--Courtois--Gallot discussed in the next subsection that the conjecture holds if one of the metrics is locally symmetric. Croke and Kleiner showed that \(C^1\) conjugacy implies that the volumes of the manifolds are the same with no restrictions on the metrics and implies isometry of the metrics if one of them has a global parallel vector (as is the case in a Riemannian product) [Cro-Klei1994].

07896 | AIM-GEOMETRY-0336

Robust compact certificates and a countable hierarchy for higher-codimension amoebas

P / partially_solved | AIM 研讨会问题汇编

Item A.16, “Nullstellensatz for amoebas,” was contributed by Kevin Purbhoo to the AIM list *Amoebas and tropical geometry*.

\[f(z_1,\ldots,z_r)=\sum_{i=1}^{\ell}m_i(z) \]

be a Laurent polynomial, where the \(m_i\) are the nonzero monomial terms of \(f\), not “of \(x\).” Equal exponents are first collected. For \(a\in\mathbb R^r\), define

\[f\{a\}= \bigl[\,|m_1(z)|,\ldots,|m_\ell(z)|\,\bigr], \qquad \operatorname{Log}(z)=a. \]

This is independent of the choice of \(z\) in the logarithmic torus fiber. A list satisfies the polygon condition when no entry is strictly greater than the sum of the other entries. Equivalently, it is not lopsided.

Theorem 1 (Purbhoo’s amoeba Nullstellensatz). If \(I\) is an ideal and \(\mathcal A(I)\) is the amoeba of its zero set in \((\mathbb C^\times)^r\), then

\[a\in\mathcal A(I) \quad\Longleftrightarrow\quad f\{a\}\text{ satisfies the polygon condition for every }f\in I. \]

\[P(f)=\{a\in\mathbb R^r:f\{a\}\text{ satisfies the polygon condition}\}. \]

For a hypersurface polynomial \(f\) and a positive integer \(m\), define its cyclic resultant

\[\widetilde f_m(z)= \prod_{\substack{u_1^m=1\\ \vdots\\u_r^m=1}} f(u_1z_1,\ldots,u_rz_r). \]

Theorem 2 (Purbhoo). The outer approximations \(P(\widetilde f_m)\) converge uniformly, in the Euclidean metric, to \(\mathcal A(f)\).

The questions ask for: (A) an explicit analogous family in higher codimension; (B) a context more general than the Archimedean and non-Archimedean cases; (C) typical, rather than worst-case, constants in the \(O(\log m/m)\) rate; and (D) applications to other open problems.

The condition rendered as \(u_i^{m_i}=1\) is \(u_i^m=1\). The isolated “10” after the cyclic product is the PDF page number. The AIM HTML page retains some of the same image-conversion typos, so Purbhoo’s arXiv source was also checked before using the product.

Ruling and weave stratifications for Legendrian (-1)-closures

P / partially_solved | AIM 研讨会问题汇编

Given a positive braid, the front projection of a Legendrian link which is its rainbow closure has an augmentation variety with a ruling stratification into \((\mathbb C^k)\times(\mathbb C^*)^l\) pieces. This stratification is the same as the one coming from the cluster variety.

Let \(\beta\in\operatorname{Br}_n^+\) have Demazure product \(w_0\), and let \(\Lambda(\beta\Delta)\) be the Legendrian \((-1)\)-closure appearing in the braid-variety/augmentation-variety correspondence, where \(\Delta\) is the positive half twist. Under the isomorphism between \(X(\beta)\) and \(\operatorname{Aug}(\Lambda(\beta\Delta))\), does the normal-ruling decomposition of the augmentation variety coincide piece by piece with a weave/cluster decomposition of the braid variety?

Scalar Curvature Question [?10]: Extend the concept ofSc > 0 to singular Fano Varieties

P / partially_solved | AMR 问题清单汇编

Problem Extend the concept ofSc > 0 to singular Fano Varieties. For example, work out a definition ofSc(X) along the lines suggested in Question 1 of the previous section, such that the non-strict positivitySc(X) ≥0 of generalised scalar curvature would be stable under deformations of smooth Fano varieties, e.g. of hypersurfacesXreg ⊂CPm+1 of low degrees, to singular ones. Noticethatthevolumesofsmallballsatsingularpointsinalgebraicvarieties, especially where they are not normal (locally reducible) are significantly greater thanthevolumesofballsattheregularpointswhichindicateofnon-applicability of the definition of scalar curvature via volumes of balls to singular spaces. (Compare with [11]-Basilio+ Sewing Riemannian Manifolds 2017].) Further example of manifolds withSc > 0 are obtained with codimension 2 surgeryon n-dimensional manifolds, i.e. surgery based on submanifolds (e.g embedded spheres) of dimensions≤n-3, since codimension 2 surgery can be(rather naturally)performed in the Riemannian category of manifolds withSc > σ. (See [122]-Walsh Metrics of positive scalar 2008] and references therein.) For instance,connected sumsof n-manifolds withSc > 0 carry metrics with Sc > 0 for alln ≥3 and all orientable manifolds withSc > 0 of dimension ≥4 can made simply connectedby attaching2-handles, while keepingSc > 0. To see geometrically how this works, look at a smallε-neighbourhood Xε = Uε(P) of a compact smooth submanifoldP in a Riemannin manifoldW.6 Ifcodim(P) ≥3 then the boundary∂Uε(P) is fibered byε-spheres of dimensionsk ≥2 the scalar curvatures of which are approximatelyk(k-1) ε2 which blows up to+∞for ε→0 and Sc(Xε) ≍ε-2→+∞ as well. 5A complex manifoldX is Fanoif theanticanonical line bundleLac(X), i.e. the top exterior power of the tangent bundleT(X), isample: some powerLN ac is generated by holomorphic sections. 6Topologically, a surgery over a manifoldX results in a manifoldW with two boundary components where the the first one isX and the second one is the result of the surgery. The geometric construction we describe may be performed in thisW with a cylindrical Riemannian metric nearX ⊂W. 9 Now, more generally, letP ⊂W be a piecewise smooth polyhedral subset,...

07910 | AMR-066-0017

Scalar Curvature Question [?17]: 6

P / partially_solved | AMR 问题清单汇编

Conjecture 6. ISC: Singularities are Irrelevant. Schoen and Yau announced 35 years ago [110], [114] that their descent metod extends to singular minimal subvarieties In a series of papers over the last decade, Lohkamp suggested an approach to the solution of this conjecture(see [86]-Lohkamp The Higher Dimensional Positive Mass Theorem II 2016where one can find references to his earlier papers). Recently, Schoen and Yau published an alternative proof of a version of the irrelevance conjecture [115]. 27 7 Flatly Twisted Spinors over Tori and their Precursors in Algebraic Topology. The kernels ofD+ andD-on the flat even dimensional torus consist of parallel spinors, where both spaces haveequal dimensions(= 2n-1); hence the ordinary index of the Dirac operator vanishes on the torus. However, these parallel spinors make the followingK-theoretic indexof D non zero not only on tori, but also on what we callover-torical manifolds X, which admit maps to then-torus of non-zero degrees, or equivalently, admitsn homology classes withnon-zero intersection index. The index of the Dirac operatorD = D+⊕D-on a Riemannian manifold X of even dimensionn we speak about takes the values in theK-theory of the torus Tm which comes about as the space of theunitary charactersofπ1(X), i.e. of homomorphismsτ :π1(X)→T, which is them-torus form=rankQH1(X). These homomorphisms define flat unitary bundleslτ, τ ∈Tm, overX which are used to "twist" the spinor bundleS = S+⊕S-overX by taking the tensor products S±⊗lτ and accordingly twist the Dirac operator on the sections of these bundles, D± τ =D± ⊗lτ :C∞(S±⊗lτ)→C∞(S∓⊗lτ) 27I have not studied the papers by Lohkamp and Schoen-Yau in depth. 21 The kernels ofD+ τ andD- τ, even though their dimensions, in general, depend onτ, may be regarded as vector bundles overTm the difference of which defines the K-theoretic index of Atiyah-Singer. ⋆If X admits homology classes h1,h 2,...,h n ∈H1(X) with non zero intersection index, h1 ⌢h2 ⌢...⌢hn ≠0 or, equivalently, if X admits a continuous map to then-torus with non-zero degree, then thisK-theoretic index is non-zero. This was shown in 1972 by Lustig [?

Scalar Curvature Question [?21]: Evaluate σ○(X0) and σ□(X0) for "simple" Riemannian manifolds X0 = (X,g 0)

P / partially_solved | AMR 问题清单汇编

Problem. Evaluate σ○(X0) and σ□(X0) for "simple" Riemannian manifolds X0 = (X,g 0). ###□Dirac operators, because they are invariant under isometries, often deliver optimal geometric inequalitiesfor manifolds withSc ≥σ. For instance, σ○(X0) and σ□(X0) are equal toSc(X0) for many (conjecturally for all) compact symmetric spaces(X0), see sections 17, but this seems hard, if possible at all, to prove with minimal hypersurfaces. Even in the most transparent case, where we know by Llarull's theorem, that if a smooth Riemannian metricg on X = Sn is greater than the spherical metricg (the differenceg-g is positive semidefinite) then there is a pointx∈X, where Sc(g)(x) ≤n(n-1) =Sc(Sn), there is no proof of this by means of minimal hypersurfaces forn≥3. (Maybe, such a proof is possible, it seems realistic forn = 3, but this is unlikely for complex and quaternionic projective spaces instead ofSn, where the Dirac operator works with no problem). On the other hand, there are incomplete manifoldsX0 where a sharp evaluation is possible by means of minimal hypersurfaces, but not by the Dirac operator methods, see section 21. Thomas Schick Example [1998].[105]. LetX =XSch be obtained from the n-torus Tn) by attaching the 2-handle to the circle representing the triplymultiple of one of the generators ofπ1(Tn). This is a spin Schoe-Yau-Schick manifold X for alln ≥4 with the fundamental groupsZn-1×Z/3Z, where all (known?

Scalar Curvature Question [?45]: Spin Problem

P / partially_solved | AMR 问题清单汇编

Spin Problem. All of the above only applies to spin maps f :X→X, for which the required twisted Dirac operator defined, and, as on similar occasions we met earlier, the necessity of the spin condition, say for equidimensional maps of degrees≠0, remains unsettled. Extremality via Lipschitz Maps.If a manifoldX admits noC2smooth length decreasing map X →X of degree≠0 which also strictly decreases the scalar curvature, then it admits no such Lipschitz map either my a simple approximation argument.

Scalar Curvature Question [?47]: Stabilisation of Extremality

P / partially_solved | AMR 问题清单汇编

Conjecture: Stabilisation of Extremality.Let X0 be a compact area extremal Riemannin manifold. Then A. X0× Rm is area gap extremal for allm. 53 B. X0× R is area extremal. This can be confirmed for all known examples ofX0 the area extremality of which was established by a Dirac operator arguments sketched in the previous section. Let us do it in two cases. Start with A for X0 = Sn, let X be a complete orientable spin Riemannian manifold, letf :X→Sn× Rm be a smooth proper map. All we shall need ofRm for our purpose is thatSc(Rm) = 0 and K-Area(Rm) =∞. Assumeforsimplicity’ssakethat misandlet Lε0 bea Q-homologically essential unitary vector bundle withε0-flat connection which is flat at infinity. Assume for the same reason thatn is even and let S+ be the "positive" spinor bundle onSn. Let L! ε0 be the f-pullback of the tensor product S+ ⊗Lε0 and observe - this needs looking at the Llarull’s computation forRL!ε0 - that if the scalar curvature ofX at infinity is≥(n(n-1)+ε > 0 and if ε0 > 0 is much smaller thanε, then the twisted Dirac operatorD⊗Lε! 0 onX is strictly positive at infinity and ifdeg(f) ≠0 it has non-zero index relative the Dirac operator twisted with the pullback ofS+. Thus,X carries non-trivial twisted harmonic spinors. On the other hand, if the scalar curvature ofX at infinity is ≥(n(n-1)+ε> 0 on all ofX and εo <ε, then again, by looking at looking at LLarull’sRL!ε0 and sees thatX can’t carry such spinors and the proof follows. "Subcomplete" Extremality. LetXo be an open, not necessarily complete Riemannin manifold.

Scalar Curvature Question [?49]: The sphereSn minus Σo is area extremal in the "subcomplete" sense for all closed subsetsΣo ⊂Sn of topological

P / partially_solved | AMR 问题清单汇编

Conjecture. The sphereSn minus Σo is area extremal in the "subcomplete" sense for all closed subsetsΣo ⊂Sn of topological dimensions k ≤1. 20 Lengths, Widths and Areas of Non-Complete Manifolds withSc > 0. To develop an adequate picture ofcomplete manifolds with scalar curvatures ≥σ one needs to understand geometric constraints imposed by the inequalitySc ≥σ on (bounded) domains in these manifolds. Thus, we look at possible sizes ofincomplete manifoldsX, e.g. (compact) manifolds with boundaries, where we do not, a priori, assume they are contained in complete manifolds with lower bounds on Sc. (We shall say something about theshapes rather than mere sizes of theseX in section 22) Asimpleexampleshowingwhatcanandwhatcannotbeexpected in this regard is the universal covering of the 2-sphere minus 2 opposite points times Rn-2, denoted ˜Σn π = the universal cover of S2\{··}× Rn-2 55 which satisfies: ●Sc(˜Σn π) =Sc(S2) = 2, ●waist1[˜Σn π]=π and width1(˜Σn π) ≤π. ●waistm[˜Σn π]=widthn-m(˜Σn π) =∞for m= 2,...,n and K-area[˜Σn π]=∞as well. ●The r-interior ˜(Σn π)-r ⊂Σn π, that is the set of pointsx which are r-far from infinity, i.e. such that the closedr′-balls Bx(r′) ⊂Σn π for r′< r are compact, hassmall all waistm and K-area, actually, zero in the present example. r-Interior and Completeness. Metric completeness of anX in this terms is equivalent to non-emptiness of ther-interior ofX for r =+∞.

Scalar Curvature Question [?50]: All of the above is satisfied, modulo constants, for alln-manifolds, possibly incomplete and/or with boundaries

P / partially_solved | AMR 问题清单汇编

Conjecture. All of the above is satisfied, modulo constants, for alln-manifolds, possibly incomplete and/or with boundaries, withSc(X) ≥σ > 0. Namely mbnd 1 widthn-1(X) ≤constnσ-1 2, mbnd 2 widthn-2(X-r) ≤constnσ-1 2 for r ≥constnσ-1 2, -bnd 2 waist2(X-r) ≤constnσ-1 for r ≥constnσ-1 2, [boundary estimate] K-area(X-r) ≤constnσ-1 for r ≥constnσ-1 2, where, of course, all theseconstn, especially the optimal ones, may be different. Among the first three inequalities, which generalise the corresponding conjecturesin section 16, a definite result is available only for mbnd 2 for 3-manifolds, which, similarly tom2, is proven with a use of minimal surfaces [54]. On the other hand, the inequality [boundary estimate], which, in the case whereX is complete spin, easily follows from the index theorem for the twisted Dirac operator, remains problematic fornon-complete, let them be spin,n-manifolds starting fromn = 3. (To make sense of this forn = 3 one should replaceK-area(X3 -r), which is zero by definition for oddn, byK-area(X3 -r× R).) It is tempting to try to reduce these conjectures, especially [boundary estimate], to the case of complete manifolds by extending (the metric on)X (onX× RN?

07963 | AMR-066-0065

Scalar Curvature Question [?69]: Shrinking of Singularities

O / open | AMR 问题清单汇编

Conjecture. Shrinking of Singularities. Let X be a compact orientable Riemanninn-manifold, f0 :X →Tn be a continuous map of non-zero degree, hi, i=0,1,2,..., be 1-dimensional homology classes in Tn which generate H1(Tn) and let εi →0 be positive numbers. Then the above (regularised for prudence) spaces Xi satisfy diam(X′ i)→0 for i→∞. 64 Moreover, theminimalhypersurfaces Yi ⊂X′ i becomenon-singular for sufficiently largei and the manifoldsX′ i as well asXi admit λibi-Lipschitz homeomorphisms to flatn-toriYi withλi→1 fori→∞. This conjecture implies that overtorical manifoldsX, (i.e. admitting maps toTn with non-zero degrees) withSc(X) ≥0 are, in fact, flat, since the scalar curvature is semicontinuous under "Lipschitz limits". (The proof of this semicontinuity forC0-convergence given in [49] automatically extends to the Lipschitz convergence.) (The arguments used in in [86] and those in [115], for the proof of this "non-positivity"Sc(X) >/0 probably yield the proof of the above Conjecture as well.) 24 Scalar Curvature and Mean Curvature. One may think of positive scalar curvature asRiemannian internalisation of the concept ofmean convexity, where a Riemannian manifoldY with boundary, e.g. a smooth domainY in a larger Riemannian manifold, is calledmean convexif the boundary∂Y has positive mean curvature. This "internalisation": is motivated by the following. Doubling Lemma[52]. The naturalC0-Riemannian metricg0 on the double56 X =Y+∂Y of a manifold(Y,∂Y)withSc(Y) ≥0 and withmean.curv(∂Y) > 0 along the boundary can beC0-approximated by C2-metrics g with withSc(g) > 0, where, moreover, this approximation isC2 away from the "∂-edge"Z∂ ⊂X where the two copies of Y meet inX. This is achieved by (1) Smoothingg0 with Sc > 0 close toZ∂ by rescaling along the geodesics normal toZ∂ (a five line argument) + (2) redistribution of positivity ofSc on all ofX by aC2-small conformal deformation (another 5 lines). Also there is a similarity between the following "thin" spaces with mean.curv > 0 and withSc > 0. Thinmean> 0. Givenaclosedsubset Y inaRiemannian n-manifold X, definevol∂(Y) as the infimum of the(n-1)-volumes of the boundaries of arbitrarily small neighbourhoodsU ⊃Y of Y...

Scalar Curvature Question [?6]: that the surface-tangent-bundle condition in Llarull's scalar-curvature rigidity theorem is redundant

P / partially_solved | AMR 问题清单汇编

Conjecture that the surface-tangent-bundle condition in Llarull's scalar-curvature rigidity theorem is redundant. Specifically, let X be a closed orientable Riemannian n-manifold with $\operatorname{Sc}(X)\geq n(n-1)$. If a C^1 map $f:X\to S^n$ has nonzero degree and does not increase the area of any surface, must f be an isometry without assuming that $T(X)$ restricts trivially to every closed surface?

背景链接：https://www.ihes.fr/~gromov/wp-content/uploads/2018/08/101-problemsOct1-2017.pdf

07965 | AMR-066-0066

Scalar Curvature Question [?70]: Let a domainY ⊂Rn havemean

P / partially_solved | AMR 问题清单汇编

Conjecture Let a domainY ⊂Rn havemean.curv(∂Y) ≥ n-k+ε for someε> 0 and k = 2,...,n -1. ThenY-1 admits a continuous map onto a(k-1)-dimensional polyhedral space space, say Δ:Y-1→Pk-1, such that the pullbacks of all points are uniformly bounded, diam(Δ-1(p)) ≤const=const(n,ε). Thus, the macroscopic dimension (see below) ofY-1 is ≤k-1. (The extremal case whereε= 0 is seen inY =Bn-k(1)× Rk ⊂Rn, where Rk admits no continuous map to any Pk-1 with uniformly bounded pullbacks of allp∈P by Lebesgue Lemma.) In particular, If Y ⊂Rn is a connected domain withmean.curv(∂Y) > n-2+ε then the subsetY-1 ⊂Y is bounded. (Recall that the macroscopic dimension of a metric spaceM is the minimal dimension of polyhedral spacesP, for whichM admits a continuous map Δ :M →P, such thatdiamM(Δ-1(p)) ≤d for some constantd=d(M).) Now let us formulate the scalar curvature conjecture of the above conjecture. Start with a few definitions. Length Metrics in Spaces of Maps.The space Φ of mapsφ from X to S, whereS is a metric space comes with thesup-metric dist(φ1,φ 2) = sup x∈X dist(φ1(x),φ 2(x)). Let us endow subsets inΦ with the correspondinglength metrics: such a metric on aΨ⊂Φ is the supremum of the metrics which locally agree with the supmetric onΨ, which the same (except for irrelevant pathological cases) as the metric defined via the length of curves inΨ. What is interesting is that this length metric in a Ψ may be significantly greater than the sup-metric, which happens whenΨ is distorted inside Φ. Examples. (A) Continuous Maps Let Ψ = C(X→S) ⊂Φ be the space ofcontinuous maps X→S with the above length metric and let ˜S →S be a locally isometric covering map.65 Then the corresponding mapC(X→˜S)→C(X→S) is an isometry. It follows that the space of maps from then-ballBn to a compact spaceS with an infinitefundamental group hasinfinite diameter. 65Here and below we assume that our spaces are locally contractible, e.g. manifolds or cell complexes and thatS is alength metric space, e.g. a Riemannian manifold. 70 But ifS has finite fundamental group, then the spaceC(Bn→S) has finite diameter. For instance, diam(C(Bn→Sm(1)))=diam(Sm(1)) =π for m> n. Somewhat less obviously, diam(C(Bn→Sn(1)))≤3π,...

Scalar Curvature Question [?79]: InvarianceandNon-invarianceof Scn(Y) = +∞

O / open | AMR 问题清单汇编

Conjecture. InvarianceandNon-invarianceof Scn(Y) = +∞. The inequalitySc[n] gn(Y) =+∞is independent of the Riemannian metric g in W ⊃Y Moreover it is a bi-Lipschitz invariant. But it is not a topological invariant. There is no serious evidence here, but there are a few examples. For instance, givenk = 1, 2,...,n -2 and μ > 0, one can arrange nested neighbourhoodsVεi, i= 1, 2,..., of flatk-subtori inW = Tn+1 such that Sc(∂Vεi) →∞and such that the Lebesgue measure of their (solenoidal) intersectionY will be equalmes(W)-μ. (With a little effort, one can make a similar construction with all Vε homeomorphic to thek-ball.) On the other hand, there, probably, existcompact zero dimensional (Cantor) setsY ⊂Rn+1 with Sc[n] n(Y) ≠+∞. (Compare 5.3 in [48].) 78

07978 | AMR-066-0076

Scalar Curvature Question [?80]: Stabilisation under Cartesian Products

O / open | AMR 问题清单汇编

Conjecture. Stabilisation under Cartesian Products. [Sc[n] gn(Y) =+∞]⇔[Sc[n+k] g⊕gkn(Y × Xk) =+∞], where Xk = (Xk,gk) is a compact Riemannian manifold of dimension k and where W × Xk ⊃Y × Xk is endowed with the metric g⊕gk. Notice that the implication [Sc[n] gn(Y) =+∞]⇒[Sc[n+k] g⊕gkn(Y × Xk) =+∞] is obvious for compact manifoldsXk without boundaryas well as for comple tenon-compactmanifoldswiththescalarcurvaturesbounded from below where the leading example isXk = Rk. Possibly, this remains true for compact manifoldswith boundary. The reverse implication [Sc[n+k] g⊕gkn(Y × Xk) =+∞]⇒[Sc[n] gn(Y) =+∞], probably, fails to be true forn = 2 and, possibly, forn = 3, 4 but it is plausible forn≥5. Relaxing C2-Smoothness of ∂Vε to C1. The requirement for the existence metrics withSc > σ →∞on the boundaries of domainsVε ⊂W whichapproximate Y ⊂W intheabovedefinitionof Sc[n] gn(Y) =+∞iscompoundedwiththenecessityoftheseboundaries to be isometrically embeddable to(W,g).67 This complication can be removed by applying to the NashKuipertheoremonisometric C1-embeddingsandallowing Vε tohave C1-smoothboundaries, yet withC2-smooth, rather than continuous, induced metrics, where it would be even more natural to admitcontinuous metrics on ∂Vε. However the extension of the inequality Sc ≥σ to continuous metrics is a non-trivial matter. 26 Manifolds with Small Balls. The definition of the scalar curvature in terms of the volumes of small balls in section 1 suggests the following. Say that ametric measure spaceX = (X,dist,vol) where vol = volX is the measure onX, called herevolume, islocally volume-wise smaller than another such spaceX′= (X′,dist′,vol′) and write X ≺volX′ 67There is variety of obstructions to embeddablity of surfaces to 3-spaces (see a brief overview of basic examples in section 3.2.3 in [42]) but amazingly little is known forn≥3. 79 if allε-balls inX are smaller than theε-balls inX′, vol(Bx(ε)) ≺vol′(Bx′(ε)) for all x ∈X,x′∈X′and some continuous positive functionε = ε(x,x′). Cartesian Additivity. Observe that X ≺volX′and Y ≺volY ′ imply that X× Y ≺volX′× Y ′, where the product spaces are endowed withvolX×Y =def volX⊕volY and with the Pythagorean product metrics,...

Scalar Curvature Question [?82]: C0-ContinuousGuth-GerochLowerVolume Bound for Balls in the Coverings of Essential Manifolds

P / partially_solved | AMR 问题清单汇编

Conjecture. C0-ContinuousGuth-GerochLowerVolume Bound for Balls in the Coverings of Essential Manifolds. [57]. The universal coverings ˜X of Q-essential n-manifolds X with continuous Riemannian metrics containR-balls ˜B(R) of all radii R> 0 such that vol(˜B(R)) ≥vol(Bn Eucl(R)). The main justification for5 is the following rough version of it. Corollary to Guth' Mesoscopic Filling Radius Theorem [55, 57]. The universal coverings ˜X of Q-essential Riemanniannmanifolds X containR-balls ˜B(R) of all radiiR> 0 such that vol(˜B(R)) ≥εnvol(Bn Eucl(R)) for some universal constantεn > 0. (d) The sharp bound here, i.e. withεn = 1 is available forlarge balls by the following result. Burago-Ivanov Asymptotic Ball Volume Theorem[21].68 If the universal cover ˜X of an Q-essential manifold X admits a sequence of balls ˜B(Ri) ⊂ ˜X,Ri →∞, (where Ri depend on the metric inX), such that vol(˜B(Ri)) ≤vol(Bn Eucl(Ri)), then X is flat. 68This paper is aboutX homeomorphic Tn; the general case reduces to that by the classification of groups of polynomial growth. 82 (e) The Burago-Ivanov argument automatically extends tononRiemannian manifolds and pseudomanifolds (X,dist) with arbitrarymetricsandsuitablydefined"volumes"onthem, namely Hilbert volumes Hilbert-volume (see [46]). (These "volumes" are not, a priori, additive.) Guth' theorem also remains valid for all(X,dist, Hilbert-volume) which motivates the following.

Scalar Curvature Question [?85]: C0-Density of C0-metrics with Volumically Positive Scalar Curvatures

P / partially_solved | AMR 问题清单汇编

Conjecture. C0-Density of C0-metrics with Volumically Positive Scalar Curvatures. Continuous Riemannian metrics withScvoln > 0 on anX are dense in the spaces of all Riemannian metrics onX for alln-dimensional manifoldsX forn≥3.69 (This may be compared withLohkampC0-Approximation Theorem [82]: C2-metrics with Sc ≤-1 are C0-dense in the spaces of all Riemannian metrics on n-manifolds X for n≥3.) On the other hand, it seems probable that most known properties of smooth manifolds withSc > 0 generalise to spaces with "benign singularities", e.g. toAlexandrov spacesX with sectional curvatures bounded from below by-1. (Ageodesicmetricspace 70 isAlexander Kapovitch Petrunin Alexandrov geometry 2017with sect.curv ≥-1 if, for every quadruple of points xi ∈X, i = 1, 2, 3, 4, there exists a quadruple of pointsx′ i in the hyperbolic planeH2 with sectional curvature -1, such that 69Conformal representation of metrics on surfaces makes this approximation unlikely for n=2. In fact, it may be safer to assumen≥4. 70"Geodesic" means that every two pointsx1 andx2 inX can be joined by a path of length d=dist(x1,x 2). 83 distH 2(x′ i,x′ j) =distX(xi,xj) for i,j = 1, 2, 3, while distH 2(x′ i,x′ 4) ≤ distX(xi,x 4), see [4] and references therein.) The simplest among expected results is the following.

Scalar Curvature Question [?87]: but there are no apparent examples (if any) where these inequalities are strict

P / partially_solved | AMR 问题清单汇编

but there are no apparent examples (if any) where these inequalities are strict. Everything we know aboutK-area+ easily extends to the the FredholmKarea where the main gain iscovariant functorialityof the FredholmK-area, such as follows. Fredholm Push-forwards of under possibly infinite covering maps.Let f : X→Y be a covering between oriented Riemannin manifolds. There is an obviouspush forward mapfrom Hilbertian bundlesL overX to Hilbertian bundles overY, sayL↦M =f∗(L), where the fiber of the bundle M over y ∈Y equals the Hilbertian sum of the fibers ofL over the pullback f-1(y) ⊂X, My = ⊗.big.disp x∈f-1(y) Lx. For instance, ifX =Y ×Σ→Y is the trivial covering with all fibers equal to a given countable setΣ and L is the trivial line bundle, thenM is the trivial bundle with the fiberl2(Σ). Now if Φ:L1→L2 is a Fredholm homomorphism which is an isomorphism at infinity, then the corresponding homomorphism between the pushed forward bundles, say Ψ:M1→M2 is also Fredholm as well as isomorphic at infinity. And since, clearly, the pushed bundles have the same curvatures, ||curv(M1,2)||= ||curv(L1,2),|| 71This is usually defined for compact spacesX where the operators are required to be bounded. We shall use below unbounded operators and our spaces may be sometimes noncompact. 85 the FredholmK-areas of the fundamental homology classes ofX andY, assuming these are manifolds or pseudomanifolds, satisfy:
FredholmK-area[X1]≥FredholmK-area[X2]. More generally letf :X→Y be a fibration where the fibersZy ⊂X have positive dimension and let them carry Riemannian structures continuous in y ∈Y. Let Θ(Zy) besomebundleover Zy associatedwiththetangentbundle T(Zy) and let the Θ-push-forward L↦ Θ M = f∗Θ(L) be defined by taking the space Hy of the square integrable sections ofL|Zy ⊗Θ(Zy), (whereL|Zy denotes the restriction ofL to Zy) for the fiberMy. Assume the fibersZy are closed even dimensional spin manifolds, let the restrictions L|Zy be endowed with unitary connections continuous iny ∈Y and let Dy :S+⊗My→S-⊗My be the Dirac operators onZy twisted withL|Zy. If L is a finite dimensional bundle then the operatorsDy are Fredholm72 and the resulting Fredholm bundle overY serve asf∗(L). (The spinor...

Sections, projections, polarity, and an ellipsoid obstruction

P / partially_solved | AIM 研讨会问题汇编

The PDF declares \(IK\) to be the intersection body, \(\Pi K\) the projection body, \(\mathcal P(K)\) the volume product, \(K|u^\perp\) the orthogonal projection, \(\operatorname{St}_u\) Steiner symmetrization with respect to \(u^\perp\), and \(B_p^n\) the unit ball of \(\ell_p^n\). With symbols restored, its twelve questions are:

1. If \(IK\subset IL\) and \(\Pi K\subset\Pi L\), must \(K\subset L\)? 2. Under the same inclusions, must \(\operatorname{vol}(K)\leq\operatorname{vol}(L)\)? The PDF says this is true for \(n\leq4\). 3. For every convex (symmetric) body \(K\), is there \(u\in S^{n-1}\) such that \[\operatorname{vol}\bigl(\operatorname{St}_u(K)^*\bigr) \leq C\operatorname{vol}(K^*)? \] 4. Is the averaged version \[\int_{S^{n-1}}\operatorname{vol} \bigl(\operatorname{St}_u(K)^*\bigr)\,du \leq C\operatorname{vol}(K^*)? \] 5. If \(K\) is the symmetric convex hull of a fixed number of independent Gaussian vectors, is \(\mathbb E\mathcal P(K)\geq\mathcal P(B_\infty^n)\)? 6. Given an even log-concave probability measure \(\mu\), estimate \(\mu(K)\mu(K^*)\) from above. The PDF prints, with a single factor on the right, that \(\mu(K)\mu(K^*)\leq\mu(B_2^n)\) is known if \(\mu\) is unconditional. 7. In Question 6, characterize equality and find a lower bound in the unconditional case. 8. Consider \(\mu^*\) in the sense of Artstein--Milman and ask the analogous questions for \(\mu(K)\mu^*(K)\). 9. For symmetric convex bodies \(K,L\subset\mathbb R^n\), is \[N(K,L)\leq\bigl[N(L^*,cK^*)\bigr]^\delta \] for absolute constants \(c,\delta\)? 10. For independent uniform \(X\in K\) and \(Y\in K^*\), compare the first “100” moments of \(\langle X,Y\rangle\) with Gaussian moments up to a factor \(1+\varepsilon\). 11. Prove Mahler's conjecture for finite-dimensional normed spaces embedding in \(L_p\), \(p<1\), in particular for convex intersection bodies (associated in the PDF with \(p=-1\)). 12. If \(1<p<2\) and the \(n\)-dimensional space \(X\) embeds in \(L_p\), is \[\mathcal P(B_X)\geq\mathcal P(B_p^n)? \]

Direct inspection shows no equal-volume hypothesis in Question 1 and no printed square on \(\mu(B_2^n)\) in Question 6. Since the latter display lacks a scale convention, it may be workshop shorthand; it is reproduced faithfully rather than silently amended.

Several questions remain underspecified even after faithful recovery. Questions 3--4 do not say whether \(C\) is dimension-free, how the polar is centered for nonsymmetric \(K\), or whether \(du\) is normalized. Questions 6--8 do not state a scale or normalization for \(\mu\) or \(\mu^*\). Question 10 does not specify covariance normalization, an asymptotic parameter, or what “same” means. These omissions are not silently repaired below.

Semi-local versus tame-at-infinity generating families

P / partially_solved | AIM 研讨会问题汇编

Question 1.2. Which \(L\) admit generating functions? One wants to impose some restrictions on the generating function. Typically one wants the generating function to be quadratic at infinity, although it might be interesting to explore other conditions at infinity. The notes add that stabilizations (zig-zags) are “somehow prohibited” in dimension \(3\), and report a theorem of Giroux when no condition at infinity is imposed.

Its question is deliberately tentative:

The following paragraph says that a suitable generating function supports Morse-theoretic invariants. The record then starts a separate **Theme 1.3**, concerning Lisa Traynor's generating-function polynomials and linearized contact homology. I therefore use the comparison only to illuminate existence obstructions and do not treat it as a second problem to solve here.

The preceding source record fixes the convention

\[J^1(M)=T^*M\times\mathbb R_z,\qquad \alpha=dz-p\,dq, \]

and describes the front generated by fiber-critical values of a function on a bundle over \(M\).

Two qualifications are essential to recover a precise modern question.

1. “Generating function” is now usually called a **generating family**. 2. The verified Giroux theorem concerns a **germ, or semi-local generating family, near its fiber-critical locus**. It is not by itself a theorem producing a global function with prescribed behavior at infinity.

Separate criteria for metric and measure entropy attainment

P / partially_solved | AIM 研讨会问题汇编

MR1348316 is M. Handel and B. Kitchens, *Metrics and entropy for non-compact spaces*, Israel Journal of Mathematics 91 (1995), 253--271, with an appendix by D. J. Rudolph.

whether the two extrema \[h_{\mathrm{Borel}}(f) =\sup_{\mu\in\mathcal M_f}h_\mu(f), \qquad h_{\mathrm{top}}(f) =\inf_{d\in\mathcal D_X}h_d(f) \] can be attained simultaneously for a geodesic flow on a noncompact metric space. Here \[h_d(f)=\sup_{K\subset X\ \mathrm{compact}}h_d(f,K), \] \(\mathcal M_f\) is the set of invariant Borel probability measures, and \(\mathcal D_X\) is the set of distances inducing the topology of \(X\). The record says that the Borel and topological entropies coincide for locally compact spaces by the unresolved key \(\mathrm{MR1348316}\).

That key can be resolved precisely:

There are, however, three points requiring correction or interpretation.

1. Handel--Kitchens prove the general inequality \[\sup_{\mu\in\mathcal M_f}h_\mu(f) \leq \inf_{d\in\mathcal D_X}h_d(f) \tag{1.1} \] and give an example in which it is strict. Thus the record's sentence attributing equality in full locally compact generality to MR1348316 is inaccurate as written. 2. Later work of Patrão and of Caldas--Patrão introduced a locally compact topological entropy for which \[\sup_\mu h_\mu(f)=h(f)=\min_{d\in\mathcal D_X}h_d(f) \tag{1.2} \] on locally compact separable metrizable spaces. Caldas--Patrão allow an arbitrary continuous map. 3. For a geodesic flow \(g_t\), the displayed discrete-time notation is read as \(f=g_1\). The distance \(d\) is a compatible distance on the phase space \(T^1M\), not necessarily the Sasaki distance or a distance induced by varying the Riemannian metric on the base manifold.

Under the entropy convention in (1.2), metric attainment is now known very generally. Measure attainment is the substantive dynamical issue.

08014 | AIM-GEOMETRY-0257

Sharp local systolic inequality near the round two-sphere

S / solved | AIM 研讨会问题汇编

Question 8.7.2 (Babenko). Does every Riemannian metric on S^2 with area 4π that is close enough to the round metric have a closed geodesic with length $\le 2\pi$?

$\operatorname{dias}(M,g)\le C\sqrt{\operatorname{genus}(M))}\sqrt{\operatorname{area}(M,g)}$,

The source first defines $\operatorname{sys}(S^2,g)$ as the least length of a nontrivial (equivalently here, nonconstant) closed geodesic. The exact question is:

The paragraph beginning “For surfaces of higher genus Gromov proved ...” follows the question and supplies context for Section 8.7; it is not an additional hypothesis or part of the requested conclusion.

with an extra closing parenthesis after $\operatorname{genus}(M)$. The same extra parenthesis is visible in the source PDF; the intended formula is evidently $C\sqrt{\operatorname{genus}(M)}\sqrt{\operatorname{area}(M,g)}$. Nothing below depends on that contextual formula.

Let g_0 denote the unit round metric, so

$$ \operatorname{Area}(S^2,g_0)=4\pi, \qquad \ell_{\min}(g_0)=2\pi. $$

The phrase “close enough” has no topology attached to it and therefore is not literally a complete mathematical proposition. The strongest conservative recovery is:

- in the C^2 topology on smooth Riemannian metrics, and hence in every C^r topology with $r\ge2$ and in the smooth Fréchet topology, the answer is yes; - an independent contact/Finsler theorem gives a C^3 neighborhood of every Zoll Finsler metric; - the sources checked do not justify replacing “close” by C^1, C^0, or merely bilipschitz closeness.

Thus “solved” below always means the natural C^2/C^∞ reading, which is also the reading explicitly identified as the Babenko--Balacheff conjecture in the solving paper.

08031 | AIM-GEOMETRY-0005

Signed curl spectra, component purification, and connected minimizers

P / partially_solved | AIM 研讨会问题汇编

The canonical AIM record 2.2, “Curl eigenvalue,” considers a bounded Lipschitz set \(\Omega\subset\mathbb R^3\) of volume \(1\) and formally writes \[\operatorname{curl}u=\mu u,\qquad u\cdot\nu=0\text{ on }\partial\Omega, \qquad \int_\Omega u\cdot w=0 \quad\text{for every }w\in L^2(\Omega)\text{ with }\operatorname{curl}w=0. \tag{1} \] It asks to minimize the first positive eigenvalue \(\mu _1(\Omega)\) under the volume constraint. It also gives the squared variational formula \[\min\{\mu _1(\Omega)^2,\mu _{-1}(\Omega)^2\} =\inf_{u\ne0} \frac{\int_\Omega|\operatorname{curl}u|^2} {\int_\Omega|u|^2}, \tag{2} \] with the stated constraints.

The following repairs and qualifications are necessary.

1. The operator domain, not merely \(C^1(\Omega;\mathbb R^3)\), is essential in (2). The precise zero-flux Giga--Yoshida realization is given in Section 3 below. 2. The spectrum is ordered as \[\cdots\le\mu_{-3}\le\mu_{-2}\le\mu_{-1}<0 <\mu_1\le\mu_2\le\mu_3\le\cdots, \tag{3} \] with \(\mu_k\to+\infty\) as \(k\to+\infty\) and \(\mu_k\to-\infty\) as \(k\to-\infty\). The source’s final “\(\cdots\to\infty\)” describes only the positive tail; read as a statement about both tails it is wrong. 3. Formula (2) characterizes the least absolute eigenvalue \[\beta(\Omega):=\min\{\mu_1(\Omega),-\mu_{-1}(\Omega)\}, \tag{4} \] not \(\mu_1(\Omega)\) alone. The two can differ on an individual domain. 4. A “domain” is often connected by definition, while the source begins with “set.” Component arguments below concern the relaxed class of finite disjoint unions of Lipschitz domains. They are not silently applied to an operator on an infinitely disconnected open set. 5. The source’s unconditional phrase that a smooth optimum is not axisymmetric is stronger than the cited theorem. Enciso--Peralta-Salas exclude \(C^{2,\alpha}\) axisymmetric local optima under a mild additional condition; in particular, they exclude all such domains with convex meridional section and hence the ball. Gerner later broadened the rotational obstruction, but the papers checked do not exclude every imaginable axisymmetric geometry without qualification.

The live AIM page itself was unavailable in this run, so no unrecorded source wording is assumed.

Signed variation of cotangent Dehn-twist powers and the five-dimensional negative stabilization

P / partially_solved | AIM 研讨会问题汇编

This is Question 1.33 (Giroux), under “Sixth day,” in the AIM workshop notes *Holomorphic Curves in Contact Geometry*.

1. **Generation and the boundary twist.** A contact structure on a closed manifold is represented by a Stein/Weinstein open book, hence by a boundary-relative symplectomorphism of its page, modulo stabilization. Are such symplectomorphisms generated by Dehn twists about parametrized Lagrangian spheres? For an integral closed symplectic manifold \((W,\omega)\), a high-degree Donaldson hypersurface \(H_k\) has Stein complement \(F_k=W\setminus H_k\). The annulus-fiber twist near \(\partial F_k\), equivalently the canonical fibered boundary twist, is boundary-relative. Is it a product of ordinary Lagrangian-sphere twists? If \(F_k\) is subcritical and contains no Lagrangian sphere, is this monodromy isotopic, even topologically, to the identity? 2. **Odd powers and the Ustilovsky examples.** The standard contact structure on \(S^{2n+1}\) is supported by the positive Dehn twist \(\phi\) on the cotangent page. Do \(\phi^3,\phi^5,\ldots\) produce Ustilovsky's contact structures on \(S^{4m+1}\)? Can \(\phi\) and \(\phi^3\) be distinguished by Floer homology, perhaps after stabilization, and how does that compare with contact homology? More generally, what happens when each Dehn twist in an open-book factorization is replaced by an odd power? 3. **Left-handed stabilization.** Attach a Weinstein handle to a Stein page along the boundary of a Lagrangian disk, obtaining a Lagrangian sphere, and compose the old monodromy with a left-handed Dehn twist about that sphere. The underlying closed manifold is unchanged. Is the resulting contact structure different and is it unfillable? The notes specifically propose \(S^5\) and one left-handed twist “in \(UT^*(S^2)\).”

There is one necessary dimensional correction to that last phrase and to the informal use of \(T^*S^n\): the compact page is \[P_n=D^*S^n, \] the disk cotangent bundle, while \(UT^*S^n=\partial D^*S^n\) is its boundary and becomes the binding. The monodromy is compactly supported, hence the identity on a collar of the boundary.

Question 10.1.3. Let F_1,F_2 be Finsler metrics on a closed surface of genus ≥ 2. Assume every (unparameterized) F_1-geodesic is an F_2-geodesic. Must F_1 be obtained from F_2 by multiplication by a constant and adding a closed form?

The next paragraph asks the analogous question on arbitrary closed manifolds admitting a hyperbolic metric, records Matveev's affirmative Riemannian result, and points to the first integral associated to trajectory-equivalent metrics.

There is an orientation convention hidden in “unparameterized.” In modern Finsler projective geometry, and in Lang's theorem resolving this question, it means the same **oriented** curves up to orientation-preserving reparameterization. This matters because a nonreversible Finsler metric need not have the reversed curve as a geodesic. Under this standard convention, the apparently one-way hypothesis already gives equality: through every $(x,[v]_+)$ (a point and positive tangent ray), each strongly convex Finsler spray has one local oriented unparameterized geodesic. If the F_1-curve is an F_2-curve, uniqueness makes it the F_2-curve with that ray; varying the ray identifies both families. If instead one reads “geodesic” as an unoriented point set, the statement is genuinely ambiguous for asymmetric metrics. The counterexamples below are reversible, so they refute either reading.

08064 | AIM-GEOMETRY-0240

Solved cylinder rigidity and invariance of sublinear opening

S / solved | AIM 研讨会问题汇编

- “Riemann-ian” is the line-broken word “Riemannian”; - the basepoint is \(p_0\), not \(p\,0\); - the denominator is \(\operatorname{dist}(p,p_0)=d(p,p_0)\); - “with the based at \(p\)” means “based at \(p\)”; - the sentence beginning “7.1. Divergence of geodesics” belongs to the next section and is not part of Conjecture 7.0.4.

For comparison with the primary solution, \(l(p)\) should be read as the length of a shortest **noncontractible** loop based at \(p\). Such a minimizing based loop is geodesic away from its basepoint. Equivalently, after lifting \(p\) to the universal cover, it is represented by a minimizing segment to a suitable nontrivial deck translate.

The displayed limit is a full limit: \(p\) ranges over all points of the cylinder with \(d(p,p_0)\to\infty\). Since a complete connected Riemannian manifold is proper, this is escape from every compact set. Since a cylinder has two ends, the formula simultaneously quantifies over both ends and over every escaping sequence, not just over one chosen ray or one sequence in each end.

The basepoint \(p_0\) is arbitrary. Proposition 5.1 below proves directly that the condition does not depend on it.

08068 | AIM-GEOMETRY-0101

Source correction, the E8 origin ratio, and a shell-distribution certificate

P / partially_solved | AIM 研讨会问题汇编

Suppose we have a radial function \(f\) on \(\mathbb{R}^n\) (\(0 1\), and \(\hat f\) has double roots at \(\sqrt{2k}\) for \(k \geq 1\). Then, \[\frac{f(0)}{\hat f(0)} =-\frac{(n^4-56n^3+1184n^2-11200n+40320} {16(n-10)(n-14)(n-18)}. \]

Suppose we have a radial function \(f\) on \(\mathbb{R}^n\) (\(0<n<10\)) such that \(f\) has a single root at \(\sqrt2\), double roots at \(\sqrt{2k}\) for \(k>1\), and \(\hat f\) has double roots at \(\sqrt{2k}\) for \(k\ge1\). Then, \[\frac{f(0)}{\hat f(0)} =-\frac{(n^4-56n^3+1184n^2-11200n+40320} {16(n-10)(n-14)(n-18)}. \]

Rendered mathematically, the corrupted field says:

This loses most of the hypotheses between the opening parenthesis and the phrase “and \(\hat f\),” and the numerator contains an unmatched parenthesis.

The saved original AIM page recovers the following text and attributes it to Cohn:

Thus the missing root conditions and the range \(0<n<10\) are verified. The AIM page itself still has the unmatched parenthesis and does not specify the Fourier normalization, the function class, whether \(n\) must be integral, or the nonvanishing of \(\hat f(0)\). The database labels the item “1.5”; its position between 1.48 and 1.52 makes this numerically the same label as 1.50, not a change in mathematical content.

The exact polynomial and the intended analytical context occur in Henry Cohn and Stephen D. Miller, *Some properties of optimal functions for sphere packing in dimensions 8 and 24*, arXiv:1603.04759, Section 6. Their conjecture is \[R(n):=\frac{f(0)}{\widehat f(0)} =-\frac{n^4-56n^3+1184n^2-11200n+40320} {16(n-10)(n-14)(n-18)} \qquad(0<n<10). \tag{1} \] This verifies that the extra opening parenthesis in AIM is a typo and that the numerator closes after \(40320\).

Crucially, Cohn--Miller do not start with an arbitrary radial function. For each finite \(K\), they construct a unique normalized polynomial--Gaussian \[f_K(x)=q_K(|x|^2)e^{-\pi|x|^2},\qquad f_K(0)=1, \tag{2} \] of degree \(4K-1\), with prescribed simple and double zeros for \(f_K\) and \(\widehat f_K\). The largest third of the finite set of root locations is moved outward by a specified \(K\)-dependent perturbation. They conjecture that \(f_K\) and \(\widehat f_K\) converge locally uniformly near the real axis, that the limiting functions have no unexpected real roots, and then conjecture (1) for this particular limit. They explicitly use \[\widehat f(\xi)=\int_{\mathbb R^n}f(x)e^{-2\pi i x\cdot\xi}\,dx. \tag{3} \] They also explain that the parameter \(n\) need not be an integer in their Laguerre/Bessel-transform formulation. By contrast, the literal phrase “on \(\mathbb R^n\)” only makes sense for integral \(n\).

Accordingly, there are two distinct readings:

1. **Literal AIM reading:** for an integer \(1\le n\le9\), every sufficiently regular radial function with the listed zeros has ratio (1). 2. **Cohn--Miller reading:** for a real parameter \(0<n<10\), the specifically normalized limiting sequence (2), if it converges in the conjectured manner, has ratio (1).

These readings are not known to be equivalent. The second is the source-supported intended conjecture. The first requires additional uniqueness and well-posedness hypotheses that the AIM page omits.

Sparse-normal formulas for perimeters and related cube-section functionals

P / partially_solved | AIM 研讨会问题汇编

On page 2 it gives the title **“Max/min Perimeter of central cross-sections,”** proposed by Hermann König, and asks:

1. Find the central cross section \[u^\perp=\{x\in\mathbb R^n:x\cdot u=0\} \] of \[B_\infty^n=\{x\in\mathbb R^n:|x_i|\leq 1\} \] with the largest perimeter. 2. Which central cross section has smallest perimeter? 3. What happens for mean width or intrinsic volume instead of perimeter? 4. What happens in other codimensions? 5. What happens for other measures, such as Gaussian measures? 6. What happens for the perimeter of projections?

Only these six questions are treated here.

For \(n\geq3\), write \(Q_n=[-1,1]^n\), \(H_u=u^\perp\), and use \[P_n(u):=\mathcal H^{n-2}\!\left(\partial_{H_u}(Q_n\cap H_u)\right) =\mathcal H^{n-2}(\partial Q_n\cap H_u). \] This is the convention used in the later solution of the maximum problem. For \(n=2\), the corresponding \(\mathcal H^0\)-measure of the two boundary points is \(2\), independent of \(u\). The case \(n=1\) is excluded because the relative boundary convention degenerates.

Spinorial nullities, Yamabe sign, and Lorentzian finiteness

P / partially_solved | AIM 研讨会问题汇编

Problem 14: How t(g) and h(g) relate to other conformal invariants?

On a spin manifold \((M,g)\) with complex spinor bundle \(S\), the spin connection decomposes into the Dirac and twistor components. The note sets

\[h(g)=\dim_{\mathbb C}\ker D_g,\qquad t(g)=\dim_{\mathbb C}\ker P_g, \]

where \(D_g\) is the Dirac operator and

\[(P_g\psi)(X)=\nabla_X^S\psi+\frac1nX\mathbin{\cdot}D_g\psi \tag{1.1} \]

is the twistor (Penrose) operator, using the Clifford convention \(X\mathbin{\cdot}X=-g(X,X)\). The source explicitly says that both dimensions are conformal invariants, that the Riemannian case was comparatively well studied, and that the surrounding questions concern the Lorentzian case. Problem 13 asks for a classification with \(t>0\) or \(h>0\), Problem 15 asks specifically about conformal Cartan holonomy, and Problem 16 asks about null-geodesic dynamics.

The question omits four hypotheses that materially change its meaning: signature, compactness, spin structure, and the function space/domain used for \(D_g\). This report fixes those hypotheses in each theorem. All dimensions are complex dimensions and the spin structure is held fixed under conformal rescaling.

08111 | AIM-GEOMETRY-0338

Stable contour graphs and their toric ends

P / partially_solved | AIM 研讨会问题汇编

For \(f\in\mathbb C[x_1,x_2]\), let \(C_f\subset\mathbb R^2\) denote the contour of the amoeba of \(f\). The singular points \(V\) on \(C_f\) divide it into arcs \(E\), giving a planar graph \((V,E)\). What combinatorial properties does this graph have, and which graphs can be realized by a polynomial? How does this generalize to higher dimension?

The AIM source (problem A.18 from the workshop *Amoebas and tropical geometry*) asks:

The contour lies in \(\mathbb R^2\), whereas critical points lie on the complex curve. The standard reconstruction is as follows. Regard \(f\) as a Laurent polynomial on the algebraic torus (ordinary polynomials are included), put \[C=\{f=0\}\subset(\mathbb C^*)^2, \qquad \operatorname{Log}(z,w)=(\log|z|,\log|w|), \] and define \[\Sigma=\operatorname{Crit}(\operatorname{Log}|_C), \qquad \mathcal K_f=\operatorname{Log}(\Sigma). \] Thus the contour \(\mathcal K_f\) is the set of **critical values**. If \(C\) is smooth, its logarithmic Gauss map is \[\gamma:C\longrightarrow\mathbb {CP}^1, \qquad \gamma(z,w)=[z f_z:w f_w], \] and \(\Sigma=\gamma^{-1}(\mathbb {RP}^1)\). Critical points of \(\gamma\) are instead its ramification points and form a different set.

The PDF's broken words “Com-puting” and “nu-merically” are line-wrap artifacts. Its 2003 Passare--Tsikh preprint appeared in 2005. Monomial factors do not change the curve in the torus, so Laurent notation is the natural one.

08115 | AIM-GEOMETRY-0271

Stationary theta graphs on every circle-symmetric Riemannian two-sphere

P / partially_solved | AIM 研讨会问题汇编

A graph \(G\) in a Riemannian surface \((S,g)\) is called a stationary net if every edge is a geodesic and if at every vertex the sum of diverging unit vectors is zero. Vertices must have valence at least \(3\).

Question 11.1.1 ([Has--Mor1996]). Does every metric on \(S^2\) admit a stationary \(\Theta\)-graph?

That material begins the next problem and is not part of Question 11.1.1.

The intended convention is recovered from Hass--Morgan's source paper. Their geodesic net is a graph **embedded** in the surface. Thus the target is an embedded copy of the abstract theta multigraph: two distinct vertices \(p\ne q\), three positive-length embedded geodesic arcs joining them, no self-intersection of an edge, and pairwise disjoint edge interiors. The three edges are distinct geometric arcs. Loops, coincident vertices, zero-length edges, repeated/overlapping edges, or an immersed three-cage with extra crossings do not answer the original question.

All edges have unit weight. At each vertex one takes the three unit tangents directed outward from that vertex and requires their vector sum to vanish. For three unit vectors in a Euclidean plane this is equivalent to pairwise angles exactly \(2\pi/3\). Later authors sometimes use “geodesic net” for an immersed weighted multigraph, allowing loops and intersections; results under that convention must not silently be substituted for the Hass--Morgan question.

08116 | AIM-GEOMETRY-0342

Statistical algebraic geometry and an exact random-binomial law

P / partially_solved | AIM 研讨会问题汇编

This record is Section A.22, “Statistical algebraic geometry,” contributed by Steve Zelditch to the AIM workshop list *Amoebas and Tropical Geometry*. It is a collection of four related research questions rather than a single assertion.

1. For random real plane algebraic curves of degree \(N\), determine the most probable and expected number of connected components. 2. For random spherical harmonics of degree \(N\), determine the most probable and expected number of nodal domains. 3. For \(m\) random real \(f\)-fewnomials of degree \(N\), with spectra chosen among \(f\)-element subsets of \(\mathbb Z_+^m\cap N\Sigma\), determine the expected number of real common zeros. Variants keep Newton polytopes fixed and dilate them, or use Kac coefficients instead of projectively normalized coefficients. 4. For a random holomorphic section \(s\in H^0(M,L)\), count and describe the critical points solving \(\nabla s=0\), noting their dependence on the Hermitian metric and connection.

The fewnomial upper bound displayed in the original slide is \[\nu(m,f)\le 2^{m^2f(f-1)/2}(m+1)^f. \] The source also displays a preliminary zero-density formula formed from an average over spectra \(S\in\mathcal S(N,f)\) and the restricted kernel \[\Pi_{N\mid S}(x,y)=\sum_{\beta\in S}\binom N\beta x^\beta y^\beta. Accordingly, no claim below uses that normalization.

There is a further mathematical ambiguity in “the \(O(m+1)\)-invariant measure.” Invariance alone does not determine a unique Gaussian ensemble on real homogeneous polynomials: the representation decomposes into harmonic summands, whose variances can be weighted differently. Thus the first question has no unique numerical answer until the covariance is specified. The Kostlan and real Fubini-Study ensembles already give different growth orders.

This report gives a status update on all four strands and proves a complete fixed-support special case of the third strand.

Stein fillability, augmentation, and the curvature defect of cylindrical contact homology

P / partially_solved | AIM 研讨会问题汇编

Conjecture: for any Stein fillable contact manifold, the cylindrical contact homology is defined. (As some have used it in the past, CCH is defined if there exists a contact form with no contractible Reeb orbits of certain Maslov indices. If such a form exists, then any two such forms give the same CCH. For this conjecture, one might not be able to eliminate bad contractible orbits, but one could hope that one can make them somehow “algebraically cancel”.) If so, then counting pairs of pants etc. gives operations on the CCH, as in Floer theory of symplectomorphisms.

Submetries of Compact Ptolemy Spaces

O / open | Oberwolfach 报告问题汇编

Let X be a compact Ptolemy space satisfying these R-circle axioms: any two points lie on an R-circle; a fourth point satisfying Ptolemy equality with three points on an R-circle lies on that circle; closest-point projection to an R-circle is self-dual; and every Möbius map between R-circles extends to a Möbius automorphism of X. For every $\omega\in X$, does there exist a submetry $\pi_\omega:X\setminus\{\omega\}\to B_\omega$, where B_ω is isometric to $\mathbb R^k$, such that Möbius automorphisms induce compatible homotheties of the bases? The completed fibers $F\cup\{\omega\}$ should be K-circles homeomorphic to S^p, with $k+p=\dim_\partial X$, and satisfy: two distinct points determine a unique K-circle; a K-circle and an R-circle meet in at most two points; if $F\cup\{\omega\}$ is a K-circle and $x\notin F\cup\{\omega\}$, a unique R-circle through x and ω meets F; and, for two distinct fibers F,F' and two R-circles through ω meeting F,F', any third fiber that meets one of those R-circles also meets the other.

Subword complexes as boundary complexes of brick compactifications

P / partially_solved | AIM 研讨会问题汇编

For the brick (cluster) compactification of a braid variety, which boundary strata are present, what are their closure relations, and when does this combinatorics agree with cluster-complex or brick-polytope combinatorics?

The exact AIM record asks:

The demonstrative “this” is ambiguous in isolation. The two immediately preceding records in the same section ask:

1. whether a braid variety has a natural compactification whose smaller strata also carry cluster structures; and 2. whether brick manifolds can be obtained by cluster-theoretic means.

The 2023 AIM workshop summary confirms this reading: it considers the inclusion of the braid variety \(X(\mathbf i)\) into its brick variety \(\operatorname{brick}(\mathbf i)\), reports that the latter is a cluster compactification, and asks about further polytopal and positive-geometric structure. Thus the recovered question is:

This report answers the first two parts exactly, gives the precise finite-type case in which the subword and cluster complexes agree, and exhibits a small obstruction to any word-independent identification in general.

08142 | AIM-GEOMETRY-0092

Symmetry obstruction and invariant-subprogram collapse for the AIM lattice three-point bound

P / partially_solved | AIM 研讨会问题汇编

\[\inf\Big\{f(0,0): f\in\mathcal S(\mathbb R^{2n}),\ \widehat f(0,0)=1,\ \widehat f\geq0,\ f\leq0\text{ on }C_2\Big\}^{1/2}, \]

\[C_2=\Big\{(x,y):\|x\|,\|y\|,\|x-y\| \in\{0\}\cup[1,\infty)\Big\}\setminus\{(0,0)\}. \]

It says that this bounds optimal lattice sphere-packing center density, reports numerical equality with the Cohn--Elkies bound and apparent invariance under $O(n)\times O(n)$, and asks for an explanation and maps between the two programs.

1. **Why “three-point”?** The three points are $0,x,y$, whose three pairwise differences have norms $\|x\|,\|y\|,\|x-y\|$. Thus a scalar function on $\mathbb R^n\times\mathbb R^n$ can encode a three-point constraint. 2. **The square root is structural.** Poisson summation is over $\Lambda\times\Lambda$, so it produces the square of the reciprocal covolume. Taking a square root is correct. 3. **Density convention.** With minimum lattice-vector length normalized to 1, the displayed objective directly bounds the number density $\operatorname{covol}(\Lambda)^{-1}$. The conventional scale-invariant center density is $2^{-n}\operatorname{covol}(\Lambda)^{-1}$, and packing density is $\operatorname{vol}(B_{1/2}^n)\operatorname{covol}(\Lambda)^{-1}$. Thus factors must be restored according to convention. 4. **The stated group is not a symmetry.** The condition on $\|x-y\|$ is invariant under simultaneous rotations $(x,y)\mapsto(Ux,Uy)$, but not under independent rotations $(x,y)\mapsto(Ux,Vy)$. Therefore independent averaging is not legitimate for this program.

The capitalization of “Lattice” has no mathematical effect. A later primary source uses a related but different constraint that also requires $\|x+y\|\in\{0\}\cup[1,\infty)$; this is not silently inserted into the recovered AIM statement below.

We use the Fourier convention

\[\widehat f(\xi,\eta)=\int_{\mathbb R^{2n}}f(x,y)\, e^{-2\pi i(x\cdot\xi+y\cdot\eta)}\,dx\,dy. \]

08151 | AIM-GEOMETRY-0422

Targeted punctured curves versus full SFT, with a Liouville-period bridge to Clifford boundary rigidity

P / partially_solved | AIM 研讨会问题汇编

With those corrections, the question asks how much of Eliashberg's proposed SFT proofs of (i) the Audin conjecture and (ii) weak boundary rigidity of the Clifford torus in \(S^3\) truly needs the then-unfinished foundations of symplectic field theory. It suggests replacing holomorphic curves with boundary on \(L\) by punctured curves asymptotic in \(T^*L\), reducing a recurring part of the analysis to curves in \(T^*(T^n)\). It also asks, without formulating a precise conjecture, whether CR structures can be useful.

The preceding questions fix the intended statements:

1. **Audin conjecture.** Every Lagrangian torus \(L\subset\mathbb C^n\) has minimal Maslov number \(N_L=2\). 2. **Weak boundary rigidity in dimension four.** Let \[\Lambda=S^1(1/\sqrt2)\times S^1(1/\sqrt2) \subset \partial\overline B^4(1)=S^3. \] If a Lagrangian torus \(K\subset\overline B^4(1)\) is Hamiltonian isotopic to \(\Lambda\) through the ball, must \(K\subset S^3\)?

The official PDF and the nearby Questions 1.19 and 1.25 were checked directly. The phrase about CR structures has no sufficiently precise mathematical target, so no theorem is claimed about it here.

Tetrahedra are sharp among three-dimensional pyramids

P / partially_solved | AIM 研讨会问题汇编

Suppose \(\Omega\subset\mathbb R^3\) is convex, has volume \(1\), and has center of mass at the origin. If \[A_{ij}=\int_\Omega x_i x_j\,dx, \] the ball minimizes \(\det A\). Which shape maximizes \(\det A\)? The scale-invariant functional in dimension \(n\) is \(\det A/|\Omega|^{n+2}\). In dimension two the maximizer is a triangle; is a simplex the maximizer in dimension three?

Here and below a convex body is compact, convex, and has nonempty interior. The archived source URL is <http://aimpl.org/symmetrybreaking/3/>.

There are two normalization points worth making explicit. For a convex body \(K\subset\mathbb R^n\), put \[V_K=|K|,\qquad b_K=\frac1{V_K}\int_Kx\,dx, \] \[M_K=\int_K(x-b_K)(x-b_K)^T\,dx, \qquad \Sigma_K=\frac{M_K}{V_K}. \] Then the source matrix \(A\) is \(M_K=\Sigma_K\) only when \(V_K=1\) and \(b_K=0\). The invariant objective is \[\mathcal I(K):=\frac{\det M_K}{V_K^{n+2}} =\frac{\det\Sigma_K}{V_K^2}=:L_K^{2n}. \] For every invertible affine map \(x\mapsto Tx+a\), \[M_{TK+a}=|\det T|\,T M_KT^T, \qquad \det M_{TK+a}=|\det T|^{n+2}\det M_K, \] so \(\mathcal I\), equivalently the isotropic constant \(L_K\), is invariant under *all* invertible affine maps. Thus equality shapes can only be unique up to affine equivalence.

P / partially_solved | AIM 研讨会问题汇编

The PDF asks about lazy random walks on graphs or reversible Markov chains. Its intended worst-case total-variation mixing time is

\[\tau_{\mathrm{TV}}(1/2) :=\min\left\{t\ge0: \max_{x\in\Omega}\lVert P^t(x,\cdot)-\mu\rVert_{\mathrm{TV}} \le\frac12\right\}. \tag{1} \]

The displayed question is whether a universal constant \(c>0\) exists such that

\[\tau_{\mathrm{TV}}(1/2) \le c\max_{x,A:\,\mu(A)\ge1/2}\mathbb E_x T_A, \tag{2} \]

where \(T_A\) is the first hitting time of \(A\) from \(x\). We use the standard convention

\[T_A=\inf\{t\ge0:X_t\in A\}; \tag{3} \]

thus \(T_A=0\) if the starting state already belongs to \(A\). The PDF writes this random time as \(T_{A,x}\) and then places an expectation in front of it.

The source sentence leaves the quantifier on \(x\) implicit; the standard mixing-time convention and the displayed maximum on the right make the worst-case interpretation (1) unambiguous. The finite-state, irreducible, discrete-time formulation is the one used in the paper that resolved the problem. Its precise laziness hypothesis is

\[P(x,x)\ge\frac12 \quad\text{for every }x. \tag{4} \]

The PDF literally places \(\mu(A)\) before a maximum in the expression \(c\,\mu(A)\max_{x,A}\mathbb E T_{A,x}\), which leaves \(A\) free in a factor outside its own maximum. It is not a subscripted constant \(c_{\mu(A)}\). Aldous's theorem, and all later precise formulations, show that the intended quantity is

\[t_{\mathrm{prod}} :=\max_{x,A:\,\mu(A)>0}\mu(A)\mathbb E_xT_A. \tag{5} \]

The Hofer diameter of equators and a bounded graphical chamber

P / partially_solved | AIM 研讨会问题汇编

This is Question 1.24 in Michael Hutchings's AIM outline *Holomorphic curves in contact geometry*, written with help from Yasha Eliashberg and John Etnyre.

\[\operatorname{length}\{L_t\} :=\int_0^1\left(\max_{L_t}F_t-\min_{L_t}F_t\right)dt, \] and \[d(L_0,L_1):=\inf_{\gamma}\operatorname{length}(\gamma), \] where \(F(x,t)\) generates the Hamiltonian isotopy \(\{L_t\}\) and the infimum is over Hamiltonian paths from \(L_0\) to \(L_1\). The source then asks for the diameter of the space \(\mathscr L\) of smooth simple closed curves in \(S^2\) dividing it into two equal-area regions. It also asks about the analogous orbit of \(\mathbb RP^2\subset\mathbb CP^2\) and records the graph map \[\operatorname{Ham}(M,\omega)\longrightarrow \mathscr L(M\times M,\omega\oplus-\omega). \]

No mean-zero normalization of \(F_t\) is needed for the displayed length: adding any time-dependent spatial constant changes neither maximum minus minimum. More generally, two generators of the same unparametrized Lagrangian motion have restrictions to the connected curve \(L_t\) that differ by a constant, so the integrand is intrinsic to the exact Lagrangian path.

Question 5.4.1. Does there exist a closed Riemannian manifold of negative curvature such that \(E^s\) and \(E^u\) are \(C^1\) smooth, but the dimension is \(>2\) and the metric is not \(1/4\)-pinched?

The record is Question 5.4.1 in Keith Burns and Vladimir Matveev, *Open problems and questions about geodesics*.

The remainder of the record explains the motivation from Hasselblatt--Wilkinson's perturbative construction and observes that complex hyperbolic space has Lyapunov exponents \(1\) and \(2\), arising from parallel planes of curvature \(-1\) and \(-4\), respectively.

No mathematical content was silently changed. The following question about typical Lyapunov ratios and the subsequent Pollicott subsection are outside this record.

There is one important semantic ambiguity. If “\(1/4\)-pinched” means the **strict** inequality, then compact complex-hyperbolic quotients already answer the literal question affirmatively. The only nontrivial reading, and the reading used below, is that “not \(1/4\)-pinched” means worse than the **weak** quarter-pinching bound.

08206 | AIM-GEOMETRY-0132

The solid-torus quantum handlebody ideal

P / partially_solved | AIM 研讨会问题汇编

Let Σ, H as above.

i) $\mathcal{O}(\mathcal{M}_{B})\xrightarrow{def. quant.}\mathcal{A}_{q}$

ii) $\mathcal{L}\subset\mathcal{M}_{B}\Rightarrow \mathcal{I_{L}}\subset\mathcal{O}$ $(\mathcal{M}_{B})\xrightarrow{def. quant.}\mathcal{I_{L}^{q}}<\mathcal{A}_{q}$ (left ideal)

iii) $\mathcal{I_{L}^{q}}$ acts on $H^{0}(\mathbb{L}^{k},Bun_{G}(\Sigma))$ and this algebra annihilates $v_{H}\in H^{0}(\mathbb{L}^{k},Bun_{G}(\Sigma))$.

Therefore the following reconstruction is explicit rather than silently substituted.

* $\Sigma=\partial H$ is a closed oriented surface and H is a handlebody. * $\mathcal M_B(\Sigma,G)=\operatorname{Hom}(\pi_1\Sigma,G)//G$ is the Betti character variety. * $\mathcal L_H\subset\mathcal M_B(\Sigma,G)$ is the locus of boundary local systems that extend over H. * One seeks a deformation quantization $\mathcal A_q$ of $\mathcal O(\mathcal M_B)$ and a quantum **left** ideal $\mathcal I_H^q$ deforming the classical vanishing ideal $\mathcal I_H$. * Under the quantum algebra action on the level-k state space, normally written $H^0(Bun_G(\Sigma),\mathbb L^k)$, the ideal should annihilate the handlebody state v_H.

This report proves that program in the smallest nontrivial case: $G=\mathrm{SL}_2(\mathbb C)$ and $H=S^1\times D^2$. It also states carefully what transfers to a root-of-unity TQFT state and what remains unproved about the holomorphic-section realization.

08207 | AIM-GEOMETRY-0208

The solved Finsler two-or-infinity conjecture and an orbit-covering audit

S / solved | AIM 研讨会问题汇编

Conjecture 2.2.1 (Long, Bangert, Problem 15 from [Alvarez2006]). Every irreversible Finsler metric on \(S^2\) has either exactly two or infinitely many distinct prime closed geodesics.

Matveev, *Open problems and questions about geodesics*, an extended report from the August 2010 International Workshop on Geodesics [BM21]. The paper later appeared in *Ergodic Theory and Dynamical Systems* **41** (2021), 641--684.

After repairing line breaks and typography, the source statement is:

The following source paragraph says that Hofer--Wysocki--Zehnder's work on contact \(S^3\) implies this dichotomy for a bumpy Finsler metric on \(S^2\), provided stable and unstable manifolds of every hyperbolic closed geodesic intersect transversely; it also cites Harris--Paternain and notes that the two closed geodesics in Katok's example are elliptic [HWZ03, HP08].

- The corpus string `irre-versible` is only a line-break hyphen; the word is **irreversible**. - `S2` is \(S^2\); the 2 is a superscript in the PDF. - The citation key is `[Alvarez2006]`. Its bibliography entry is Juan Carlos **Álvarez Paiva**, *Some problems on Finsler geometry*, Handbook of Differential Geometry, vol. II (2006), pp. 1--33 [AP06]. The displaced acute accents near the name and just after the closing parenthesis in the PDF are typesetting artifacts, not mathematical notation. - The corpus ends with `4 KEITH BURNS AND VLADIMIR S. MATVEEV`. This is the running footer/header created at the page break, not part of the problem. - The paper calls the item Conjecture 2.2.1 and attributes it to Long and Bangert while identifying it with Problem 15 in Álvarez Paiva's list. The canonical number `15` should not be confused with the paper's section number.

The count is orientation-sensitive in the standard Finsler convention used by Bangert--Long: a prime closed geodesic is considered up to time translation and is not an iterate. For an irreversible metric, the reversed parametrization need not be a geodesic. If it is, it is counted separately [BL10]. “Prime” does not mean embedded in the base; a prime geodesic may self-intersect.

08209 | AIM-GEOMETRY-0190

The symplectic-volume proportion of unknotted spatial polygons

P / partially_solved | AIM 研讨会问题汇编

Problem 1 in that document supplies the missing notation. For a length vector $\ell=(\ell_1,\ldots,\ell_n)\in\mathbb R_{>0}^n$, let

$$ M_\ell= \left\{(u_1,\ldots,u_n)\in(S^2)^n: \sum_{i=1}^n\ell_i u_i=0\right\}/SO(3). $$

This is the moduli space of labeled closed spatial polygons with those edge lengths, modulo orientation-preserving Euclidean motions. Let Σ be the locus of non-embedded polygons. The source writes

$$ M_\ell\setminus\Sigma=\bigsqcup_i U_i, $$

where the U_i are connected components. Klyachko's symplectic reduction gives a symplectic form ω on a generic M_ℓ, and hence Liouville volume. The intended question is to understand

$$ P_0(\ell):= \frac{\operatorname{Vol}_\omega \left(\bigsqcup_{i\in I_0}U_i\right)} {\operatorname{Vol}_\omega(M_\ell)}, \qquad I_0=\{i:U_i\text{ consists of unknots}\}. \tag{1} $$

Here “unknot” must mean an embedded polygon ambient-isotopic to a round circle. The equality printed in the PDF, $\ell_1+\cdots+\ell_{n-1}=\ell_n$, is genuinely an equality, not a lost inequality sign. It is nevertheless a degenerate boundary case, and its assertion that the proportion is exactly one is incompatible with the preceding embedded-polygon definition; see Section 8.

08221 | AIM-CONVEX_GEOMETRY-0008

Three-dimensional vertex index and the choice of center

P / partially_solved | AIM 研讨会问题汇编

Section 9, Problem 2. Find the best possible universal upper bound for the vertex index of a three-dimensional centrally symmetric convex body.

For an origin-symmetric convex body \(K\subset\mathbb R^n\), the preceding Problem 1 defines \[\operatorname{vein}(K) =\inf\left\{ \sum_{i=1}^{N}\|p_i\|_K: N<\infty,\quad K\subseteq\operatorname{conv}\{p_1,\ldots,p_N\} \right\}, \tag{1.1} \] where \[\|x\|_K=\inf\{t>0:x\in tK\} \] is the norm whose unit ball is \(K\).

Section 9, Problem 3. Provide an upper bound, for a general convex body \(K\subset\mathbb R^n\), for the quantity displayed in the PDF as \[\inf\left\{ \sum_{i=1}^{N}\|p_i\|_{K-a}: a\in K,\quad K-a\subseteq\operatorname{conv}\{p_1,\ldots,p_N\} \right\}. \tag{1.2} \] The PDF really says \(a\in K\), not \(a\in\operatorname{int}K\).

The heading “10 Reconstruction of Polytopes with Few Facets (or Few Vertices)” and the following sentence about estimating polytopes from random points begin the next section. They are context spill, not part of either vertex-index problem.

There is a genuine definitional issue in (1.2). If \(a\in\partial K\), then \(0\notin\operatorname{int}(K-a)\), so the usual Minkowski functional of \(K-a\) is not a finite gauge on all of \(\mathbb R^n\), much less a norm. We therefore keep two readings separate:

1. the **standard repaired reading**, with \(a\in\operatorname{int}K\); 2. the **literal boundary-allowed reading**, only after defining the functional as extended-valued, possibly \(+\infty\).

All positive structural results below use the standard repaired reading.

08237 | AMR-054-0054

Traveling Salesman Problem in Solid Grid Graphs

O / open | AMR 问题清单汇编

What is the complexity of finding a shortest tour in a solid planar grid graph? A planar grid graph is a graph whose vertices are any set of points on the planar integer lattice and whose edges connect every pair of vertices at unit distance. Distances between nodes correspond to induced shortest-path distances in the graph, which corresponds to ``Manhattan'' distances. A grid graph is solid if it does not have any holes, i.e., its complement in the planar integer lattice is connected.

Tropical Riemann--Roch and a genus-one residual test

P / partially_solved | AIM 研讨会问题汇编

A.7 What does the Riemann-Roch theorem say in the tropical world?

Background: One way to approach this would be to build up the machinery of line bundles (or maybe coherent sheaves?). A different, more immediately geometric approach might be called the "Brill-Noether" approach. This requires only two ingredients: A. "plane curve with ordinary nodes" and B. If A, B and C are curves with a common point of intersection, what is "A intersect B minus A intersect C", the "residual intersection of C in A intersect B". If O_x is the local ring of x on A, and f_B, f_C are the images in O_x of the equations of B and C, then in the classical case the parts of the intersections A intersect B and A intersect C supported at x are represented by the ideals (f_B) and (f_C) in O_x, and the residual is represented by the ideal

(f_B:f_C) := {g in O_x | g f_C is in (f_B)}.

The early work on Riemann-Roch treated only the case where A is smooth at x. Then A intersect B at x is represented just by a multiplicity, and residuation is just subtraction. When A is arbitrary, things still work because O_x is a Gorenstein ring for any smooth curve, no matter how singular. Question: How do these notions play out for tropical plane curves? (contributed by David Eisenbud)

Vertex π-Floodlights

P / partially_solved | AMR 问题清单汇编

How many π-floodlights are always sufficient to illuminate any polygon of n vertices, with at most one floodlight placed at each vertex? An α-floodlight is a light of aperture α. (We consider here ``inward-facing'' floodlights, whose defining halfspace lies inside the polygon, locally in the neighborhood of the vertex. Other models of the problem allow general orientations of floodlights or restricted orientations (e.g., ``edge-aligned'').)

Vertex-Unfolding Polyhedra

P / partially_solved | AMR 问题清单汇编

Consider a polyhedron with simply connected facets (no holes on a facet) and without boundary (every edge is incident to exactly two facets). Can the polyhedron be cut along potentially all of its edges, but leaving certain faces connected at vertices, and unfolded into one piece in the plane without overlap? Such an unfolding is called a vertex-unfolding, to distinguish from widely studied edge-unfoldings (see Problem 9) and general unfoldings. An important subproblem here is whether all convex polyhedra have vertex-unfoldings; a negative answer would also resolve Problem Problem.9.

Vertex-weight perturbations do not preserve lazy mixing time

S / solved | AIM 研讨会问题汇编

\[P_W(u,v)=\frac{W_v}{\sum_{z\in N(u)}W_z}\qquad(v\in N(u)). \]

The question is whether changing all vertex weights by a bounded multiplicative factor can change the mixing time by more than a bounded factor. The source remark says that the analogous assertion for the spectral gap is true (the PDF has the typographical error “spetral”).

The source does not specify aperiodicity. Ordinary discrete-time total-variation mixing is infinite on every connected bipartite graph for this non-lazy walk, regardless of the positive weights. We therefore use the standard \(1/2\)-lazy kernel

\[L_W=\frac{I+P_W}{2} \]

and the worst-start total-variation mixing time at threshold \(1/4\). Changing the fixed threshold in \((0,1/2)\), or using continuous time, changes the quantities below only by universal factors. Under this standard interpretation the answer is **no**.

What a parabolic de Rham Torelli theorem can recover

P / partially_solved | AIM 研讨会问题汇编

Torelli theorems on \(\mathcal M_{dR}\) with parabolic structure.

Under explicit hypotheses, does an **algebraic** isomorphism between two spaces (1.1), perhaps preserving the algebraic symplectic form or a natural determinant class, force an isomorphism of pointed curves \((X,D)\cong(Y,D')\)? Which of the rank, flags, residues, stability chamber, and determinant data can also be recovered?

It is a research program rather than a proposition with a truth value: it does not specify the curve, group, residues, weights, determinant, stability condition, or the structure that an isomorphism must preserve.

Here is a precise version of the program. This is an **added formulation**, not a silent replacement of the source. Let

- \(X\) be a smooth projective complex curve of genus \(g\), - \(D=p_1+\cdots+p_n\) a reduced marked divisor, - \(r\) the rank and \(\xi\) a determinant line bundle, - \(E_{p_i}=F_{i,0}\supsetneq\cdots\supsetneq F_{i,\ell_i}=0\) prescribed flag types, - \(\boldsymbol\lambda=(\lambda_{i,j})\) prescribed residue eigenvalues on the graded pieces, satisfying the trace/degree constraint, - \(\boldsymbol\alpha\) auxiliary generic stability weights, and - \(\nabla_\xi\) a fixed logarithmic determinant connection.

\[\mathcal M_{dR}(X,D;r,\boldsymbol\alpha, \boldsymbol\lambda,\xi,\nabla_\xi) \tag{1.1} \]

for a coarse moduli space of stable logarithmic connections \((E,F_\bullet,\nabla)\) with those data. A meaningful marked Torelli question is:

The word “algebraic” is essential. A bare biholomorphism is too weak by the Riemann--Hilbert correspondence. Rank \(r=1\) must also be excluded from any unqualified marked Torelli theorem; Section 5 gives a sharp proof.

Why fixed subtori miss the regular 3-Sasakian zero set

P / partially_solved | AIM 研讨会问题汇编

S1

Question 2.6 (C. Boyer) In the case of 3-Sasakian reduction by abelian groups, would it be possible to extract information about the cohomology of the reductions by using fixed points of smaller tori? The question is motivated by the fact that some cases of 3-Sasakian reductions of spheres by S1 is well-understood. Suppose there is a circle action on S4n+3, where the action is locally free on the whole sphere, and free on the zero level set. Then one can see explicitly that H∗

(S4n+3; Q) surjects onto H∗(S4n+3 ///S 1; Q), up to the middle dimension. The idea would be to look at the fixed point set M H for subtori H ⊂ T, where we start with the abelian group T acting on the 3-Sasakian manifold M. Note that the fixed point sets M H are contact, and for the Sasakian case, known examples of M H are spheres.

Comment 2.7 (C. Boyer) Main references for 3-Sasakian toral reductions are [BG99, BGM94, BGMR98].

3 Kirwan surjectivity for contact quotients

The official PDF, page 4, confirms the intended formula \[H_{S^1}^*(S^{4n+3};\mathbb Q)\longrightarrow H^*(S^{4n+3}///S^1;\mathbb Q) \] and the notation \(M^H\). The final line “3 Kirwan surjectivity for contact quotients” is the next section heading, not part of Question 2.6.

The recovered question is therefore: can fixed sets \(M^H\) of connected subtori \(H\subset T\) be used to compute ordinary rational cohomology of a 3-Sasakian torus reduction, extending the understood circle reductions of spheres?

Zero-Higgs restriction and the sharp rank-two pure ring

P / partially_solved | AIM 研讨会问题汇编

It also appends the beginning of Section 7, “Kernel computations for Kirwan maps,” which starts immediately after Example 6.22 in the source PDF and is not part of Conjecture 6.20.

The ambient assumptions are stated at the start of Section 6.5 of the PDF: \(C\) is the fixed complex curve (denoted \(\Sigma\) there), and the rank \(n\) and degree \(d\) are relatively prime. For the cohomological results below, assume that \(C\) is smooth projective of genus \(g\geq2\).

\[\mathcal M^d_{\mathrm{Dol}}(GL_n) \quad\text{and}\quad \mathcal N^d(GL_n) \]

for the moduli spaces of stable rank-\(n\), degree-\(d\) Higgs bundles and stable vector bundles, respectively. With the standard normalized universal classes \(a_i\in H^{2i}\), define

\[P_{\mathrm{Dol}}(n,d):=\mathbb Q[a_2,\ldots,a_n] \subset H^*(\mathcal M^d_{\mathrm{Dol}}(GL_n);\mathbb Q), \qquad P_{\mathrm{bun}}(n,d):=\mathbb Q[a_2,\ldots,a_n] \subset H^*(\mathcal N^d(GL_n);\mathbb Q). \]

The recovered conjecture says that these two graded rings are isomorphic, that this pure ring is independent of the coprime degree \(d\), and that its Poincaré polynomial \(PP_n(t)\) is determined by a partition generating series. A direct transcription of the typeset display, retaining its notation, is

\[PV_n(t)=PP_n(t)\frac{t^{2(1-g)n(n-1)}}{t^2-1}, \qquad PZ_n(t,T)=\exp\!\left(\sum_{r\geq1}\frac{PV_n(t^r)T^r}{r}\right), \]

\[PH^g_\lambda(t)=t^{4(1-g)n(\lambda')} \prod_{\substack{x\in d(\lambda)\\a(x)=0}} \frac{1}{1-t^{2h(x)}}, \qquad n(\lambda')=\sum_{z\in d(\lambda)}\ell(z), \]

\[\prod_{n=1}^{\infty}PZ_n(t,T^n) =\sum_{\lambda\in\mathcal P}PH^g_\lambda(t)T^{|\lambda|}. \]

The PDF does not define every partition statistic in this immediate display, and \(n\) is used both for rank and as a product index. I therefore preserve the formula as a source transcription and do not use it in the proof below. In particular, I do not silently repair the hook-length convention or claim that a later formula in the literature is identical to this display without a term-by-term comparison.

A compression-ladder reduction and category audit for stable four-genus

P / partially_solved | AIM 研讨会问题汇编

Stable 4-genus and 2-torsion. Find a knot \(K\) which has infinite order in \(\mathcal C\) and yet which has \(g_4^{st}(K)=0\).

The preceding canonical record defines \[g_4^{st}(K)=\lim_{n\to\infty}\frac{g_4(nK)}{n} \] “in either category.” This creates a category issue that must be resolved explicitly. Standard usage in this workshop makes unadorned \(\mathcal C\) and \(g_4\) smooth. Thus the intended reading is:

* \(K\) has infinite order in the smooth concordance group \(\mathcal C_{\mathrm{sm}}\); and * its smooth stable four-genus \(g_{4,\mathrm{sm}}^{st}(K)\) is zero.

There is also a coherent topological version, with both terms interpreted locally flat topologically, and an incoherent “mixed” version using smooth order but topological four-genus. The mixed version has easy explicit solutions (Section 5); they do not solve the intended problem.

A local-capacity obstruction for trivial bypass detection

P / partially_solved | AIM 研讨会问题汇编

Problem 7.4. Can triviality be detected via capacities on balls around the intersection point?

The record occurs in the section “Explicit contact handlebodies” of the April 2024 AIM workshop *Higher-dimensional contact topology*. The immediately preceding Problem 7.3 asks whether a trivial bypass can be characterized using the belt sphere of the contact (n)-handle and the attaching sphere of the contact ((n+1))-handle. This gives the most likely antecedent of “the intersection point”: the unique geometric intersection which makes those two handles smoothly cancel.

There is a second, closely related intersection built into the bypass attaching data. In the notation now used by Breen--Christian--Honda--Huang (BCHH), a convex hypersurface has a decomposition

\[\Sigma^{2n}=R_+\cup \Gamma\cup R_-, \]

and bypass data is a tuple

\[\mathcal D=(\Lambda_-,\Lambda_+;D_-,D_+), \]

where (D_\pm\subset R_\pm) are properly embedded Lagrangian disks with Legendrian boundaries (\Lambda_\pm\subset\Gamma), and (\Lambda_-) and (\Lambda_+) have one (\xi_\Gamma)-transverse intersection. Thus “intersection point” can also naturally refer to (p=\Lambda_-\cap\Lambda_+). The two readings lead to the same conclusion for ordinary ball capacities, and both are treated below.

BCHH’s current definition says that the data is trivial of type (TB1) if ((\Lambda_+,D_+)) is a standard Legendrian unknot with its standard Lagrangian disk and (\Lambda_+) is below (\Lambda_-); type (TB2) is the sign-reversed condition on ((\Lambda_-,D_-)). Their Proposition A.26 realizes every bypass as a smoothly canceling contact (n)- and ((n+1))-handle pair and proves that trivial data gives a vertically invariant contact cobordism. In particular, “triviality” is not merely smooth handle cancellation: every bypass pair in that proposition cancels smoothly.

The ambiguity above is retained rather than silently resolved.

A sign-splitting reduction for length-spectrum isometries

P / partially_solved | AIM 研讨会问题汇编

Problem 3.3 (A. Papadopoulos). Is \[\operatorname{Isom}(\mathcal T(S),d_{ls})=\operatorname{Mod}(S)? \]

Inspection of page 3 of the source PDF recovers the mathematical statement as

The dots are a separator. “4 WEIXU SU” is the page number and running header on the following page, not part of the problem. The preceding text says that Sorvali's length-spectrum metric is a symmetrization of the Thurston metric.

There is a genuine convention issue in the recovered statement. In much of the literature, \(\operatorname{Mod}(S)\) means orientation-preserving mapping classes, whereas an isometry theorem is normally stated using the extended group \(\operatorname{Mod}^{\pm}(S)\). The 2010 Oberwolfach formulation by Papadopoulos asks explicitly whether the isometry group *strictly contains the extended mapping class group*. Thus the intended question is best read as

\[\operatorname{Isom}(\mathcal T(S),d_{ls}) \stackrel{?}{=} \operatorname{Mod}^{\pm}(S)/K(S), \tag{1} \]

where \(K(S)\) is the pointwise kernel of the action on Teichmüller space. Without the effective quotient, equality is not literally possible in the familiar low-complexity cases.

This report treats connected orientable finite-type surfaces \(S=S_{g,n}\) of negative Euler characteristic, without geodesic boundary, and with \(3g-3+n>0\). The zero-dimensional pair of pants is a separate degenerate case: its Teichmüller space is a point and its isometry group is trivial.

Action-produced quasimorphisms and a uniform-perfectness obstruction

P / partially_solved | AIM 研讨会问题汇编

For surfaces for which this is not known, can we produce quasimorphisms using actions of $\operatorname{Map}(S)$?

Its problem text is:

The supplied literature note is:

The immediately preceding records concern homomorphisms and lattice maps, while item 4.7 asks about subgroups having infinite-dimensional spaces of quasimorphisms. The literature note also points to the ray and loop graph constructions. The safest reconstruction is therefore:

Here and below “nontrivial” means nonzero after quotienting by homomorphisms and bounded functions. This qualification is essential: a homomorphism is itself a quasimorphism, but it represents zero in the reduced space.

Unless continuity is explicitly mentioned, groups and quasimorphisms are treated algebraically. Big mapping class groups carry a natural Polish topology, so continuous quasimorphisms form a genuinely different problem.

08440 | AIM-TOPOLOGY-0014

An essential-tight bypass ladder on contact S2 x S3

P / partially_solved | AIM 研讨会问题汇编

Find other interesting explicit bypass decompositions of contact manifolds.

The record has no remarks or literature field. The prompt is deliberately open-ended: “other” refers to the preceding Problem 7.1, which asks for a bypass description of the layers between two Darboux balls in

\[(S^5,\xi_k)=\operatorname{OB}(T^*S^2,\tau^{2k+1}). \]

The official April 2024 AIM workshop report confirms this reading. Its “Explicit contact handlebodies” group sought those \(S^5\) layers and, as a three-dimensional stepping stone, computed that two overtwisted bypasses in \(\operatorname{OB}(T^*S^1,\tau^{-1})\) realize a negative plus a positive stabilization. The report says the higher-dimensional target was not completed.

This report preserves the broad prompt and develops a different explicit family: a finite ladder of nontrivial, non-overtwisted bypasses between convex \(S^2\times S^2\) levels in a tight contact \(S^2\times S^3\). It does not claim to settle every possible meaning of “find other.”

An invariant Kähler structure on the SL(3,R) Hitchin component

S / solved | AIM 研讨会问题汇编

Question 2.1 (John Loftin). Does there exist a mapping class group-invariant Kähler structure on the Hitchin component for \(\mathrm{SL}(3,\mathbb R)\)?

Comment 2.2 (Richard Wentworth). Theorem 1.0.2 of [Labourie 2007] shows that the Hitchin component for \(\mathrm{SL}(3,\mathbb R)\) is given by the bundle of cubic differentials on Teichmüller space. There is a mapping class group-invariant complex structure on this space.

Comment 2.3 (John Loftin). There is evidence for a Kähler structure, since transverse to the fibres there is a Kähler metric (Weil--Petersson), and on the fibres there is a Kähler metric.

An invariant ledger for the Thurston infinitesimal norm

S / solved | AIM 研讨会问题汇编

Problem 1.2 (K. Rafi). What properties of the hyperbolic surface are determined by the Thurston infinitesimal norm?

On its first page, under “Infinitesimal properties of the Thurston metric,” the source reads:

The PDF declares that \(S=S_{g,n}\) is a genus-\(g\) hyperbolic surface with \(n\) punctures and that \(\mathcal T(S)\) is its Teichmüller space. The question immediately follows Problem 1.1, which asks whether the norm at \(X\) determines \(X\), but Problem 1.2 asks for a broader inventory of recoverable properties.

This report interprets the datum as the **abstract real asymmetric normed vector space**

\[N_X=(T_X\mathcal T(S),\|\cdot\|_{\mathrm{Th}},X}) \]

up to surjective real-linear isometry. This convention is essential. A norm written in already marked coordinates, or a dual sphere supplied with curve labels, contains extra data not present in an abstract norm.

Applications 1 - Introduce stable homotopy theory into the world of C^*-algebras, like Voevodsky has done in algebraic…

P / partially_solved | AMR 问题清单汇编

Introduce stable homotopy theory into the world of C^*-algebras, like Voevodsky has done in algebraic geometry. More specifically, find a model structure on some category of C^*-algebras that is useful. Then stabilize it somehow to find a stable homotopy category of C^*-algebras where Kasparov's KK theory is just Hom in the category. This will probably be the same as finding a category where K-theory of C^*-algebras is representable. I have thought about this a little--almost the first thing you realize is that C^*-algebras are not closed under inverse limits, so you need pro-C^*-algebras. These have been considered by Chris Phillips in N. C. Phillips, Inverse limits of $C\sp *$-algebras, J. Operator Theory {\bf 19} (1988), no.~1, 159--195; MR 90c:46090. Another thing you realize is that it is easier to map into C^*-algebras than it is to map out of them, and so it seems likely that any model category will be fibrantly generated instead of cofibrantly generated. But not much else is clear to me. One of the people who knows the most about the combination of C^*-algebras and homotopy theory is Claude Schochet. The viewpoint I am advocating here is shared by Jim McClure, and probably Marius Dadarlat, and they may know more about this. In particular, C^*-algebraists often make an assumption about their cohomology theories which basically forces them to be K-theory--I think it is Bott periodicity. To do what I am saying, you would have to drop this assumption.

O / open | AMR 问题清单汇编

Neil Strickland points out that several different moduli spaces are used in differential geometry and physics. For example, there is the moduli space people are always talking about in every talk on gauge theory I have ever been to. I can't remember what this moduli space is now, unfortunately--something to do with connections and the gauge group? Anyway, the geometers tend to think only about the rational homology of these spaces. What about their Morava K-theory? (Neil also mentioned solitons and Seiberg-Witten theory).

Applications 4 - Stefan Stolz showed that a simply connected Spin manifold of dimension at least 5 admits a metric of p…

P / partially_solved | AMR 问题清单汇编

Stefan Stolz showed that a simply connected Spin manifold of dimension at least 5 admits a metric of positive scalar curvature if and only if its image under the orientation MSpin --> KO is 0. But the situation is not completely understand when the manifolds are not simply connected. It seems to get involved with the Novikov conjecture. Oh yes, I remember--it is actually false for some fundamental groups, but the trouble appears to be all with products with the Bott manifold. That is, the general conjecture is: suppose M is a Spin manfold of dimension at least 5. Then a product of M with some finite number of Bott manifolds admits a metric of positive scalar curvature.

Applications 6 - Improve on Benson-Carlson-Rickard.

S / solved | AMR 问题清单汇编

Improve on Benson-Carlson-Rickard. Recall their theorem: if G is a finite p-group and k is an algebraically closed field, then thick subcategories in the stable k[G]-module category (= category obtained by killing projectives = injectives = frees) are in 1-1 correspondence with subsets of Proj H^*(G,k) closed under specialization. There are several open questions related to this. The most obvious one is to remove the algebraically closed requirement. This may involve understanding some Galois theory of stable homotopy categories, but may not be too difficult. I sincerely hope that anybody who wants to work on the stable module category will make the effort to understand my work with Palmieri and Strickland on this; our setup makes things considerably simpler, in my opinion.

08459 | AMR-110-0032

Applications 8 - Extend the results of Benson-Carlson-Rickard to connected, cocommutative Hopf algebras over a field, l…

P / partially_solved | AMR 问题清单汇编

Extend the results of Benson-Carlson-Rickard to connected, cocommutative Hopf algebras over a field, like A(n). Hovey-Palmieri have achieved some partial success here; we reduce the calculation of thick subcategories to the case when the Hopf algebra is quasi-elementary. For k[G], quasi-elementary subHopf algebras look like k[E] for elementary abelian p-groups E, and the group cohomology is a polynomial algebra, so Benson-Carlson-Rickard use algebraic geometry to finish the proof (this is where they require the field to be algebraically closed). For A(n), the quasi-elementary subHopf algebras are also exterior, but the Ext groups are bigraded. We don't know how to do bigraded algebraic geometry, so we are stuck there. But I think something should be doable here. Anyway, here is the abstract of the Hovey-Palmieri paper , and here is the dvi file.

Boundary-sensitive extensions of the Thurston metric

P / partially_solved | AIM 研讨会问题汇编

Problem 3.8. Let \(S\) be a hyperbolic surface with ideal boundary. Can we define the Thurston metric on the non-reduced Teichmüller space of \(S\)?

There is no omitted attribution or remark in the PDF.

The nearby context is essential. Immediately before this question, Problems 3.6--3.7 discuss the **reduced**, finite-dimensional Teichmüller space of a compact bordered surface and its arc metric. Problem 3.8 changes both the boundary geometry and the equivalence relation:

- The **ideal boundary** is the conformal boundary of a hyperbolic Riemann surface. In a Fuchsian model it is \(\Omega_\Gamma/\Gamma\). Equivalently, in the 2024 terminology of Alekseev--Meinrenken, the interior carries a conformally compact hyperbolic or hyperbolic \(0\)-metric; its ends are funnels or trumpets and their boundary circles lie at infinite hyperbolic distance. - A reduced Teichmüller point is a marked surface modulo a conformal comparison map in the ordinary homotopy class. In the **non-reduced** (or unreduced) space, that homotopy is required to be relative to the ideal boundary. Thus boundary parametrizations are retained. For nonempty ideal boundary the resulting space is infinite-dimensional.

These meanings agree with the explicit definitions in Fortier Bourque and with the hyperbolic \(0\)-metric model of Alekseev--Meinrenken. They are distinct from the geodesic-boundary arc-metric theory of Liu--Papadopoulos--Su--Théret.

Conjecture 2.1 - The natural homomorphisms (Λ∗Λ3HQ)Sp →H ∗(Mg,∗; Q), (Λ∗UQ)Sp→H ∗(Mg; Q) induce isomorphisms (Λ∗Λ3H ∗ Q/ ([12]tore…

O / open | AMR 问题清单汇编

The natural homomorphisms (Λ∗Λ3HQ)Sp →H ∗(Mg,∗; Q), (Λ∗UQ)Sp→H ∗(Mg; Q) induce isomorphisms (Λ∗Λ3H ∗ Q/ ([12]torelli⊕ [22]))Sp ∼=R∗(Mg,∗) (Λ∗U ∗ Q/([22]))Sp∼=R∗(Mg). Furthermore, the algebras on the left hand sides are Poincar´ e duality algebras of dimensions 2g-2 and 2g- 4 respectively. Here we mention that for a single Riemann surface X, the cohomology H ∗(Jac(X); Q) is a Poincar´ e duality algebra of dimension 2 g while it can be shown that there exists a canonical isomorphism H ∗(Jac(X); Q)/([12])∼=H ∗(X; Q) which is a Poincar´ e duality algebra of dimension 2. Here [12]⊂H 2(Jac(X); Q) 354 S. Morita denotes the kernel Ker(Λ 2H ∗ Q→Q) of the intersection pairing and ([1 2]) denotes the ideal generated by it. Observe that we can write Λ ∗U ∗ Q = H ∗(PH 3(Jac)) which is a Poincar´ e duality algebra of dimension (2g 3) - 2g, where PH 3(Jac) denotes the primitive part of the third cohomology of the Jacobian variety. Hence the above conjecture can be rewritten as (H ∗(PH 3(Jac))/([22]))Sp∼=R∗(Mg) so that it could be phrased as the family version of the above simple fact for a single Riemann surface.

Conjecture 2.17 - [154] Every Vassiliev invariant of classical knots can be extended to a finite type invariant of long virtual knots.

S / solved | AMR 问题清单汇编

[154] Every Vassiliev invariant of classical knots can be extended to a finite type invariant of long virtual knots. (Se e also Problem 3.9.) 2.8 Finite type invariants derived from local moves One aspect of the study of knot invariants is the study of the s et of knots. A local move and finite type invariants derived from it might gi ve an approach of this study. A local move is a move between two knots, which are identical except for a b all, where they differ as shown in both sides of a move in Figure 10. L et R be a commutative ring with 1, and K the set of isotopy classes of oriented knots, as before. For a local move m, we define Fd(RK, m) as follows. Let K be an oriented knot with d disjoint balls B1, B2,···, Bd such that K is as shown in one side of m in each Bi. For any subset S⊂{ 1, 2,···, d}, we denote by KS the knot obtained from K by applying m in each Bi for i∈ S. We define Fd(RK, m) to be the submodule of RK spanned by ∑ S (-1)#S KS (13) for any K with d balls, where # S denotes the number of elements of S, and the sum runs over all subsets S of{1, 2,···, d}. Then, we have a descending series of submodules, RK =F0(RK, m) ⊃ F1(RK, m) ⊃ F2(RK, m) ⊃ ···. Note that Fd(RK) =Fd(RK,×) for a crossing change “ ×”. An R-homomor- phism v: RK→ R is called a finite type invariant of m-degree d, or an m finite type invariant of degree d, if v|Fd+1(RK,m) = 0. A crossing change “ ×”: ←→ A double crossing change “ ××”: ←→ A # move: ←→ A pass move: ←→ A Δ move: ←→ A doubled delta move Δ Δ: ←→ An n-gon move: ←→ Figure 10: Some local moves among oriented knots. The strand s of both sides of a Δ move and an n-gon move have any orientations such that corresponding str ands from opposite sides of the moves are oriented in the same way. Each side of an n-gon move has n strands. It is a fundamental problem of finite type invariants to calcu late the correspond- ing graded spaces, which would enable us to identify finite ty pe invariants in some sense.

Conjecture 4.1 - (Inhomogeneity of all metrics).

P / partially_solved | AMR 问题清单汇编

(Inhomogeneity of all metrics). Let Teichg denote the Teichm¨ uller space of closed, genus g≥ 2 Riemann surfaces. Let h be any Riemannian metric (or any Finsler metric with some weak regularity conditions) on Teichg which is invariant under the action of the mapping 2. Some problems on mapping class groups and moduli space 31 class group Modg, and for which this action has finite covolume. Then Isom(Teichg,h) is discrete; even better, it contains Modg as a subgroup of index C =C(g). Royden’s Theorem is the special case when h is the Teichm¨ uller metric (Royden gets C = 2 here). A key philosophical implication of Conjecture 4.1 is that the mechanism behind the inhomogeneity of Teichm¨ uller space is due not to fine regularity properties of the unit ball in Q(X) (as Royden’s proof suggests), but to the global topology of moduli space. This in turn is tightly controlled by the structure of Mod g. As one piece of evidence for Conjecture 4.1, I would like to point out that it would follow if one could extend the main theorem of [FW1] from the closed to the finite volume case. In some sense looking at Mod g-invariant metrics seems too strong, especially since Mod g has torsion. Perhaps, for example, the inhomogeneity of Teich g is simply caused by the constraints of the torsion in Mod g. Sufficiently large index subgroups of Mod g are torsion free. Thus one really wants to strengthen Conjecture 4.1 by replacing Mod g by any finite index subgroup H, and by replacing the constant C =C(g) by a constant C =C(g, [Modg:H]). After this one can explore metrics invariant by much smaller subgroups, such as Ig, and at least hope for discreteness of the corresponding isometry group (as long as the subgroup is sufficiently large). If one can prove the part of Conjecture 4.1 which gives discreteness of the isometry group of any Modg-invariant metric on Teich g, one can approach the stronger statement that Cg = 1 or Cg = 2 as follows. Take the quotient of Teich g by any group Λ of isometries properly containing Mod g. By discreteness of Λ, the quotient Teich g/Λ is a smooth orbifold which is finitely orbifold-covered byMg.

08627 | AMR-103-0093

Conjecture 4.15 - (J.

O / open | AMR 问题清单汇编

(J. Przytycki, see [286]) (1) There is a polynomial invariant of unoriented links, P1(L)∈ Z[x, t] which satisfies: (i) Initial conditions: P1(Tn) = tn, where Tn is a trivial link of n components. (ii) Skein relation P1(L0) + xP1(L1)- xP1(L2)- P1(L3) = 0 where L0, L1, L2, L3 is a standard, unoriented skein quadruple (Li+1 is obtained from Li by a right-handed half twist on two arcs involved in Li; compare Figure 15.) (2) There is a polynomial invariant of unoriented framed links, P2(L) ∈ Z[A±1, t] which satisfies: (i) Initial conditions: P2(Tn) = tn, (ii) Framing relation: P2(L(1)) =-A3P2(L) where L(1) is obtained from a framed link L by a positive half twist on its framing. (iii) Skein relation: P2(L0) + A(A2 + A-2)P2(L1) + (A2 + A-2)P2(L2) + AP2(L3) = 0. (3) There is a rational function invariant of unoriented framed links, P3(L)∈ Z[a±1, x, y, (x + y + xy + y2)-1] which satisfies: (i) Initial conditions: P3(Tn) = (-a3(x+y+xy+x2)+a7(x+y+1)2-a-1 x+y+xy+y2)n-1, (ii) Framing relation: P3(L(1)) = aP3(L), (iii) Skein relation: P3(L0)+axP3(L1)+a2yP3(L2)-a3(x+y+1)P3(L3) = 0. (4) The invariant predicted in (1) (respectively (2) and (3)) is not uniquely defined (if it exists). Note that a solution to (3) becomes a solution to (1) under the substitution a = 1, x =-y and that a solution to (3) becomes a solution to (2) under the substitution a =-A3, x =-1- A-4, y = A-4 + A-8. As for the uniqueness of (4), note that all such invariants agree on trivial links and therefore they agree on the space spanned by trivial links in the related cubic ske in module. The above conjectures assume that b∞ = 0 in our skein relation. Let consider the possibility that b∞ is invertible in R. Using the “denominator” of our skein relation (the first line of Figure 16) we get the relation whic h allows to compute the effect of adding a trivial component to a link L (we write tn for the trivial link Tn): (a-3b3 + a-2b2 + a-1b1 + b0 + b∞t)L = 0. (33) When considering the “numerator” of the relation and its mir ror image (Figure 16) we obtain formulas for Hopf link summands, and because un oriented Hopf link is amphicheiral we can eliminate it from our equations t o get the formula (34): b3(L#H) + (ab2 + b1t + a-1b0 + ab∞)L = 0. b0(L#H) + (a-1b1 + b2t + ab3 + a2b∞)L = 0. ((b0b1- b2b3)t + (a-1b2 0- ab2 3) + (ab0b2- a-1b1b3) + b∞(ab0- a2b3))L = 0. (34) It is possible that (33) and (34) are the only relations in the module. Precisely, we ask whether S4,∞(S3; R) is the quotient ring R[t]/(I) where ti represents the trivial link of i components andI is the ideal generated by (33) and (34) for L = t. The substitution which realizes the relations is: b0 = b3 = a = 1, b1 = b2 = x, b∞ = y. This may lead to the polynomial invariant of unoriented lin ks in S3 with values in Z[x, y] and the skein relation L3+xL2+xL1+L0+yL∞ = 0.

08631 | AMR-109-0043

Conjecture 4.4 - (Nonpositive curvature).

O / open | AMR 问题清单汇编

(Nonpositive curvature). For g≥ 2 the orbifold Mg admits no complete, finite volume Riemannian metric with nonpositive sectional curvatures uniformly bounded away from-∞. 5As Mg is an orbifold, technically one studies Mod g-invariant metrics on the Teichm¨ uller space Teichg. 32 B. Farb One might be more ambitious in stating Conjecture 4.4, by weakening the finite volume condi- tion, by dropping the uniformity of the curvature bound, or by extending the statement from Mg to any finite cover of Mg (or perhaps even to certain infinite covers). It would also be interesting to extend Conjecture 4.4 beyond the Riemannian realm to that of CAT(0) metrics; see, e.g., [BrF] for a notion of finite volume which extends to this context. In the end, it seems that we will have to make do with various relative notions of nonpositive or negative curvature, as in [MM1, MM2], or with various weaker notions of nonpositive curvature, such as holomorphic, Ricci, or highly singular versions (see, e.g.,[LSY]), or isoperimetric type versions such a Kobayashi or Kahler hyperbolicity (see [Mc2]). Part of the difficulty with trying to fit Mg into the “standard models” seems to be the topological structure of the cusp of Mg. Scalar curvature and Q-rank. Let S be a genus g surface with n punctures, and let M(S) denote the corresponding moduli space. We set d(S) = 3 g- 3 + n The constant d(S) is fundamental in Teichm¨ uller theory: it is the complex dimension of the Teichm¨ uller space Teich(S); it is also the number of curves in any pair-of-pants decomposition of S. While previous results have concentrated on sectional and holomorphic curvatures, Shmuel Weinberger and I have recently proven the following; see [FW2].

Conjecture 4.4 - Let M be a closed hyperbolic 4-manifold.

O / open | AMR 问题清单汇编

Let M be a closed hyperbolic 4-manifold. Then all the Seiberg-Witten invariants of M vanish. The relevance of this is given in the following proposition. We give a proof for hyperbolic manifolds that makes use only of Taubes celebrated paper [37] when b+ 2 > 1, and hence avoid complexities that arise when b+ 2 = 1. Proposition 4.5. A postive answer to Conjecture 4.4 implies that a closed hyperbolic 4- manifold M cannot be symplectic. Proof: This follows automatically from [37] in the case when b+ 2 > 1, since [37] shows that a compact oriented symplectic 4-manifold with b+ 2 > 1 has non-vanishing Seiberg-Witten invariants. Thus assume that b+ 2 (M) = 1, and M is symplectic (if b2(M) = 0 there is nothing to prove). From the discussion above, since M is hyperbolic, the signature of M is 0, and so b2(M) = 2. Also M being hyperbolic implies π1(M) is residually finite and so M has many finite covers. Let p:M1→M be a cover of degree d> 1. Since M is symplectic, M1 will be symplectic using the pullback of the symplectic form on M. We claim that b+ 2 (M1)> 1, and so we can apply [37] to get a contradiction. 282 A.W. Reid For if b2(M1) = 2, then (from the volume formula above) since the Euler characteristic satisfies χ(M1) > 0, it follows that b1(M1) < 2. However, χ(M1) = dχ(M) and this shows b1(M1) = 2-d(2-b1(M)). These remarks yield the desired contradiction. ⊔ ⊓ On the otherhand, any X that has the description of a surface bundle over a surface where both the base and fiber have genus ≥ 2 is symplectic by an old argument of Thurston (see [39] or [14] Theorem 10.2.17). Motivated by this discussion, one can ask the following generalization of Question 4.1, which is an analogue of the virtual fibering question in dimension 3.

08633 | AMR-109-0044

Conjecture 4.6 - LetS be any surface with d(S)≥ 1.

O / open | AMR 问题清单汇编

LetS be any surface with d(S)≥ 1. Then M does not admit a finite volume Riemannian metric of (uniformly bounded) positive scalar curvature in the quasi-isometry class of the Teichm¨ uller metric. The analogue of Conjecture 4.6 in the Γ \G/K case was proven by S. Chang in [Ch]. The same method of proof as in [Ch] should reduce Conjecture 4.6 to the following discussion, which seems to be of independent interest, and which came out of discussions with H. Masur. What does Mg, endowed with the Teichm¨ uller metric dTeich, look like from far away? This can be formalized by Gromov's notion of tangent cone at infinity: Cone(Mg):= lim n→∞ (Mg, 1 ndTeich) (10) where the limit is taken in the sense of Gromov-Hausdorff convergence of pointed metric spaces; here we have fixed a basepoint in Mg once and for all. This limit is easily shown to make sense and exist in our context. To state our conjectural answer as to what Cone(Mg) looks like, we will 2. Some problems on mapping class groups and moduli space 33 need the complex of curves on Σ g. Recall that the complex of curves Cg forg≥ 2 is the simplicial complex with one vertex for each nontrivial, nonperipheral isotopy class of simple closed curves on Σ g, and with a k-simplex for every (k + 1)-tuple of such isotopy classes for which there are mutually disjoint representatives. Note that Mod g acts by simplicial automorphisms on Cg.

08634 | AMR-109-0045

Conjecture 4.7 - (Q-rank of moduli space).

S / solved | AMR 问题清单汇编

(Q-rank of moduli space). Cone(Mg) is homeomorphic to the (open) cone on the quotient Cg/ Modg 6. One can pose a stronger version of Conjecture 4.7 that predicts the precise bilipschitz type of the natural metric on Cone(Mg); an analogous statement for quotients Γ \G/K of symmetric spaces by lattices was proven by Hattori [Hat]. H. Masur and I have identified the right candidate for a coarse fundamental domain needed to prove Conjecture 4.7; its description involves certain length inequalities analogous to those on roots defining Weyl chambers. Further, the (conjectured) dimensions of the corresponding tangent cones are Q-rank(Γ) and d(S), respectively. Thus we propose the following additions to the list of analogies between arithmetic lattices and Mod g. arithmetic lattices Modg Q-rank(Γ) d(S) root lattice {simple closed curves } simple roots top. types of simple closed curves Cone(Γ\G/K) Cone(Mg) As alluded to above, Conjecture 4.7 should imply, together with the methods in [Ch], the second statement of Conjecture 4.5.

08635 | AMR-109-0046

Conjecture 4.8 - (Mod g is Kahler).

P / partially_solved | AMR 问题清单汇编

(Mod g is Kahler). Forg≥ 3, the group Modg is a Kahler group, i.e. it is isomorphic to the fundamental group of a compact Kahler manifold. It was shown in [V e] that Mod 2 is not a Kahler group. This is proven by reducing (via finite extensions) to the pure braid group case; these groups are not Kahler since they are iterated extensions of free groups by free groups. A natural place to begin proving Conjecture 4.8 is the same strategy that Toledo uses in [T o] for nonuniform lattices in SU(n, 1),n ≥ 3. The main point is the following. One starts with a smooth open variety V and wants to prove that π1V is a Kahler group. The first step is to find a compactificationV ofV which is projective, and for which V-V has codimension at least 3. This assumption guarantees that the intersection of the generic 2-plane P in projective space with V misses V. The (weak) Lefschetz Theorem then implies that the inclusion i:V∩P ↪→V induces an isomorphism on fundamental groups, thus giving that π1V is a Kahler group. 6Note: This statement is a slight cheat; the actual version requires the language of orbi-complexes. 34 B. Farb One wants to apply this idea to the Deligne-Mumford compactification Mg of moduli space Mg. This almost works, except that there is a (complex) codimension one singular stratum of Mg, so that the above does not apply. Other compactifications of Mg are also problematic in this regard. What about the Torelli group Ig? This group, at least for g≥ 6, is not known to violate any of the known constraints on Kahler groups. Most notably, Hain [Ha3] proved the deep result that for g≥ 6 the group Ig has a quadratically presented Malcev Lie algebra; this is one of the more subtle properties posessed by Kahler groups. Note Akita's theorem (Theorem 5.13 above) that the classifying space of Ig,g≥ 7 does not have the homotopy type of a finite complex shows that these Ig are not fundamental groups of closed aspherical manifolds. There are of course Kahler groups (e.g. finite Kahler groups) with this property. In contrast to Conjecture 4.8, I have recently proven [F a3] the following.

Conjecture 4.8 - Each component of Hc g is simply connected.

S / solved | AMR 问题清单汇编

Each component of Hc g is simply connected. This is trivially true in genus 2, where there is one component which is all of h2. If true in genus 3, it implies quite directly the known fact that T3 is generated by 35 = 36 - 1 bounding pair elements. The number 35 is the rank of H1(J3,H3). The inverse images of generators of π1(J3,H3), once oriented, generate T3.10 The conjecture has an equivalent statement in more group theoretic terms. Define the hy- perelliptic Torelli group to be the intersection of the hyperelliptic mapping class group and the Torelli group: T Δg:= Δ g∩Tg = ker{Δg→ Spg(Z)}. It is a subgroup of the Johnson subgroup Kg:= ker{τ:Tg→ Λ3H/H}. Examples of elements in T Δg are Dehn twists on separating simple closed curves that are invariant under the hyperelliptic involutionσ. If Hg,α is a component of Hg, then there is an isomorphism π1(Hg,α,∗)∼=T Δg. The conjugacy classes of twists on a σ-invariant separating SCC correspond to loops about com- ponents of the divisor Hc,red g. Van Kampen's Theorem implies that π1(Hc g,α,∗)∼=π1(Hg,α)/these conjugacy classes ∼=T Δg/these conjugacy classes. The conjecture is thus equivalent to the statement that T Δg is generated by the conjugacy classes of Dehn twists on σ-invariant separating SCCs. It is important to understand the topology of the loci of hyperelliptic curves as it is the branch locus of the period mapping and also because it is important in its own right.

Conjecture 5.24 - (Picard number one conjecture for level L structures).

P / partially_solved | AMR 问题清单汇编

(Picard number one conjecture for level L structures). Prove that H2(Modg[L]; Q) = Q when g≥ 3. More generally, compute H2(Modg[L]; Z) for all g≥ 3,L≥ 2. Harer [Har2] proved this conjecture in the case L = 1. This generalization was stated (for Picard groups) as Question 7.12 in [HL]. The case L = 2 was claimed in [F o], but there is apparently an error in the proof. At this point even the (g,L) = (3, 2) case is open. Here is a possible approach to Conjecture 5.24 for g≥ 4. First note that, since Mod g[L] is a finite index subgroup of the finitely presented group Mod g, it is finitely presented. As we have a lot of explicit information about the finite group Sp(2 g, Z/LZ), it seems possible in principle to answer the following, which is also a test of our understanding of Mod g[L].

Conjecture 5.3 - Let hX be as above.

S / solved | AMR 问题清单汇编

Let hX be as above. Then, log hX is not a Vassiliev invariant, unless it is constant. 5.3 (Co)homology of quandles Second cohomology classes of a quandle are used in order to de fine quandle cocycle invariants of knots. They are introduced as follows. Let A be an abelian group, written additively, and let C n(X; A) be the abelian group consisting of maps X n→ A, where X n denotes the direct product of n copies of X. We put C 1 Q(X; A) = C 1(X; A), C 2 Q(X; A) ={f∈ C 2(X; A)| f (x, x) = 0 for any x∈ X}, C 3 Q(X; A) ={g∈ C 3(X; A)| g(x, x, y) = 0 and g(x, y, y) = 0 for any x, y∈ X}. The coboundary operators di: C i Q(X; A)→ C i+1 Q (X; A) are given by d1f (x, y) = f (x)- f (x∗ y), d2g(x, y, z) = g(x, z)- g(x, y)- g(x∗ y, z) + g(x∗ z, y∗ z), for f∈ C 1 Q(X; A) and g∈ C 2 Q(X; A). We define the second quandle cohomol- ogy group by H 2 Q(X; A) = (kernel d2)/(image d1). It is known that H 2 Q(X; A) is isomorphic to Hom (H Q 2 (X); A) by the universal coefficient theorem, noting that H Q 1 (X) is free abelian (see [82]). Here, H Q 2 (X) denotes the second homol- ogy group of the dual complex of {C ⋆ Q(X; Z), d⋆}. See [82] for the definition of the nth quandle (co)homology group. Therefore, to obtain H 2 Q(X; A) for any A, it is sufficient to compute H Q 2 (X). Connected quandle X Order H Q 2 (X) H Q 3 (X) R3 3 0 Z/3Z Z[t±1]/(2, t2 + t + 1) 4 Z/2Z Z/2Z⊕ Z/4Z R5 5 0 Z/5Z Z[t±1]/(5, t- 2) 0 0 R7 0 Z/7Z Z[t±1]/(7, t- 2) 7 0 0 Z[t±1]/(7, t- 3) 0 0 Z[t±1]/(2, t3 + t + 1) 8 0 Z/2Z R9 0 Z/9Z Z[t±1]/(9, t- 2) 0 Z/3Z Z[t±1]/(3, t2 + 1) 9 Z/3Z (Z/3Z)3 Z[t±1]/(3, t2- t + 1) Z/3Z Z/3Z⊕ Z/9Z Z[t±1]/(3, t2 + t- 1) 0 0 Z[t±1]/(p, t- a) p 0for any prime p and any a̸= 0, 1∈ Z/pZ Table 5: The cohomologies of the quandles, except for the las t one, in the table are due to [264]. From a table in [264] we omit one of two dual quandles and quandles that are not connected (see remarks on Problem 5.6). The 2nd homology of Z[t±1]/(p, t- a) is due to [284]. See [264, 284] for computations of cohomolog y groups of some more quandles.

S / solved | AMR 问题清单汇编

f f is pseudo-Anosov element of a mapping class group ModS with sufficiently big dilatation coefficient, then the subgroup of ModS normally generated by f is a free group having as generators the conjugates of f. More cautiously, one may conjecture that the above holds for a sufficiently high power g =fN of a given pseudo-Anosov element f. This conjecture is motivated by a theorem of M. Gromov (see [Gr], Theorem 5.3.E). According to this theorem, the subgroup of a hyperbolic group normally generated by a hyperbolic element (with sufficiently big translation length) is a free group having as generators the conjugates of this element. Of course, it is well-known that mapping class groups are not hyperbolic. But, as M. Gromov noticed, what is essential for his proof is not the global negative curvature (hyperbolicity), but the negative curvature around the loop representing the considered element in an Eilenberg- MacLane space of the group in question. So, the hope is that the Teichm¨ uller spaces have enough negative curvature along the axes of pseudo-Anosov elements for a similar conclusion to hold. For a more direct and elementary approach to Gromov’s result see the work of Th. Delzant [D]. 80 N. Ivanov This conjecture may be relevant to the Problem 3 above, since one may expect that all no- trivial elements of such subgroups are pseudo-Anosov.

08655 | AMR-109-0098

Conjecture I - f Γ is an irreducible arithmetic group of rank ≥ 2, then every homomorphism Γ→ ModS has finite image.

S / solved | AMR 问题清单汇编

f Γ is an irreducible arithmetic group of rank ≥ 2, then every homomorphism Γ→ ModS has finite image. For many arithmetic groups Γ the conjecture can be proved by combining some well-known information about arithmetic groups with equally well-known properties of Mod S. But, for ex- ample, for cocompact lattices in SU (p,q) this straightforward approach seems to fail. (I owe this specific example to G. Prasad.) In any case, by now this conjecture is completely proved. V. A. Kaimanovich and H. Masur [KaM] proved that so-called non-elementary subgroups (subgroups containing a pair pseudo-Anosov elements with disjoint sets of fixed points in Thurston boundary) of Mod S are not isomorphic to irreducible arithmetic groups of rank ≥ 2. The proof is based on the theory of random walks on Mod S developed by Masur and Kaimanovich-Masur and on the results of H. Furstenberg about random walks on arithmetic groups (see the references in [KaM]). If combined with the Margulis finiteness theorem and the techniques of N. V. Ivanov, Subgroups of Teichm¨ uller Modular Groups, Translations of Mathematical Monographs, Vol. 115, American Math. Soc., 1992, this result can be used to prove the conjecture. A proof close in the spirit to the one alluded to in the previous paragraph is due to B. Farb and H. Masur [FM]. In a addition, S-K. Yeung [Y] completed the picture by proving that any homomorphism from a lattice Γ in either Sp(m, 1) or F -20 4 (the isometry group of the Cayley plane) into a mapping class group has finite image. The lattices in the remaining simple Lie groups of rank 1 often admit non-trivial homomorphisms to Z, and, therefore, homomorphisms to the mapping class groups with infinite image.

Conjecture - Every subgroup of finite index in ModS contains a congruence subgroup.

P / partially_solved | AMR 问题清单汇编

Every subgroup of finite index in ModS contains a congruence subgroup. V. Voevodsky had indicated (in a personal communication) a beautiful application of this conjecture. Namely, the conjecture implies that a smooth algebraic curve over Q is determined up to an isomorphism by its algebraic fundamental group (which is isomorphic to the profinite completion of π1(S)) considered together with the natural action of the absolute Galois group Gal(Q/Q) on it. This corollary was apparently first conjectured by A. Grothendieck. I am not aware of any publication where this conjecture of Grothendieck is deduced from the solution of the congruence subgroup problem for the mapping class groups. The Grothendieck conjecture itself was proved by S. Mochizuki [Mo1] after the initial work by A. Tamagawa [T am]. See also [Mo3] and the expository accounts by S. Mochizuki [Mo2] and G. Faltings [F]. The proof of the Grothendieck conjecture lends some additional credibility (beyond the analogy with the classical congruence-subgroup problem) to the above congruence-subgroup conjecture.

08658 | AMR-109-0106

Conjecture - LetS and R be closed surfaces.

O / open | AMR 问题清单汇编

LetS and R be closed surfaces. Let Γ be a subgroup of finite index in ModS. If the genus of R is less than the genus of S, then there is no homomorphism Γ→ ModR having as an image a subgroup of finite index in ModR. In fact, one may hope that any such homomorphism Γ → ModR has a finite image. But while the problem 7 about H 1(Γ) is unresolved, a more cautious conjecture seems to be more appropriate and more accessible, because if H 1(Γ) is infinite, Γ admits a homomorphism onto Z, and therefore, a lot of homomorphisms into Mod R, in partucular, with infinite image. In the special case when Γ = Mod S, the conjecture is recently proved by W. Harvey and M. Korkmaz [HaK]. Their methods relay on the use of elements of finite order in Γ = Mod S, and therefore cannot be extended to general subgroupsΓ of finite index.

Continuity of Thurston geodesic envelopes and diagonal collapse

P / partially_solved | AIM 研讨会问题汇编

Problem 2.3 (K. Rafi). Does `Env(X,Y)` depend continuously on `X,Y`?

The immediately preceding Problem 2.2 in the AIM source defines

\[\operatorname{Env}(X,Y)=\bigcup\{G:G\text{ is a Thurston geodesic connecting }X\text{ to }Y\}. \]

Thus the question concerns a set-valued map on \(\mathcal T(S)\times\mathcal T(S)\). The source does not specify a topology on sets. Following Dumas--Lenzhen--Rafi--Tao and Pan--Wolf, the precise reading used here is Hausdorff continuity on nonempty compact subsets, for the symmetric metric

\[d_s(U,V):=\max\{d_{\rm Th}(U,V),d_{\rm Th}(V,U)\}. \]

The AIM document is the workshop version of Weixu Su's problem list. Its ambient surface is of finite type (genus \(g\), \(n\) punctures, negative Euler characteristic), so a result only for closed surfaces does not literally settle every case of the recovered question.
