数学猜想与开放问题

第三卷：多源补充与历史提及记录

20,360

条补充资料，另附 9,342 个参数型开放问题实例

对照前两卷 98,151 条记录筛查 / 原始出处 / 分类导航 / 排除与保留审计

来源：OEIS 官方文本、arXiv 目录、学术论坛、研究者问题集与专业数值表

由中国跨学科学者 沈阳　　124739259@qq.com　　调度 AI 生成

整理日期：2026 年 10 月 25 日（Asia/Shanghai）

收录历史提及，不等同于仍未解决；未匹配前卷，不等同于已证明数学上独立。

01 本卷结论与计数口径

本轮继续扫描前两卷未整体处理的公开来源，并以第一卷 17,614 条、第二卷 80,537 条，共 98,151 条记录为排除基准。最终保留 20,360 条补充资料；另将 9,342 个具体参数的开放取值或存在性问题放入附录。两部分合计 29,702 条来源记录。

章节	条数	实际内容
A 明示猜想与研究问题	326	来源明示的问题块、目录整理表述或有相应复用许可的 arXiv 猜想块。
B OEIS 历史与当前提及	17,579	序列名称、注释或公式中命中猜想等关键词的原段；一条序列可能涉及多个命题。
C 论坛与文献定位	2,455	1,637 个问题帖 + 818 条定位线索；帖文不等同于公认开放问题，定位项不冒充全文。
主目录合计	20,360	用于补充前两卷的资料记录数，不是经数学语义归并后的独立猜想数。
D 参数型问题实例附录	9,342	来自六个问题族的具体参数、界限或存在性实例，不计为 9,342 个命名猜想。

“人类只要提到过”的边界

历史上已证明、已反驳、曾被撤回或仅被讨论的猜想也可能有收录价值。因此，OEIS 提及和论坛问题不因“已解决”就自动删除。反过来，提到一个猜想不等于新提出了一个猜想；也不意味着来源中的推测仍然成立或仍未解决。

无法证明已经穷尽全网、所有语言、所有纸本文献和所有历史版本。本卷的“前卷之外”意为按公开列明的规则未匹配到前卷；不同措辞的等价命题仍可能漏检，保守的题目族匹配也可能排除真正的新变体。

02 本轮实际扫描的范围

来源与取得方式	本次处理范围	需要保留的限定
OEIS 官方 Git 文本导出 [S1]	400,652 个 .seq 序列文件	仅在名称 N、注释 C、公式 F 字段检索 conjectur*、hypothesis/hypotheses、open problem/question；不以参考文献标题单独命中。
OpenConjecture 公开发布集 [S2]	4,415 个候选块	采用来源标为 real_open_conjecture 的 3,531 条进入比对；该标签由模型生成。上游的 26,747 篇论文并非本报告逐篇通读。
ConjectureBench [S3]	14,865 条记录	含 302 条编目、5,221 条扩展目录、9,342 个参数实例；此前已处理的集合镜像先排除。
图论论文/书籍定位集 [S4]	768 条论文记录 + 38 条书籍定位	来自第三方自动抽取或整理。本卷只保留定位资料，不用其自动状态评估认证数学结果。
Epoch / OEIS 元数据 [S5]	492 条历史定位	包含由模型生成的概述；本卷采用序列号、提出者、日期和记录名作为回查线索。
MathOverflow / Math Stack Exchange [S6]	2,269 个不同问题帖	完整翻页取得 MO 的 open-problems、conjectures 两标签及 MSE 的 conjectures 标签；不声称涵盖未打这些标签的讨论。
Randomstrasse 101 [S7]	18 篇博客，38 个明示问题块	按网页标注的 conjecture / openproblem 块提取；完整上下文可回到原文。

输入版本：OEIS 导出时间为 2026-10-24T03:00:17-04:00；OpenConjecture 发布集日期为 2026-07-12；ConjectureBench 参数表观察日期多为 2026-07-23。论坛和博客为本轮获取版本。上述快照时间不同，不能合称为同一时点的“当前全部未解问题”。

03 如何与前两卷排除重合

比对使用前两卷正文记录，以及第一卷中 417 条可映射回主记录的归档别名。先做固定序列号、论文号、来源页面、规范化题名和表述匹配，再做文本相似度筛查，最后合并第三卷内部的相同条目与来源线索。

阶段	数量	处理解释
进入前卷比对的候选	38,527	已去除旧集合镜像、来源标记不适合的候选及部分非数学提问。
匹配前卷或触及已知题目族	7,279	含同一 OEIS 序列、同一 arXiv 论文、相同来源页、题名、文本和已知命名猜想提及；是保守排除，不全是已证明的语义重复。
疑似重合，暂不收入正文	628	标题加权 TF-IDF 词/二元词余弦相似度不低于 0.50；保存最相近前卷编号。
第三卷内部初次去重	748	同一序列、相同文本、题名或相同源文件定位。
来源之间追加归并	54	例如论坛帖子链接到本卷同一 OEIS 项；或历史定位对应已暂缓的题目族。
题名与人工编辑规则复查	116	检查短题名是否包含在前卷较长题名中、同名提出者题目族，以及投稿流程等非数学帖子。
本卷全部保留记录	29,702	其中主目录 20,360；参数实例附录 9,342。

可复算：38,527 - 7,279 - 628 - 748 - 54 - 116 = 29,702。机器相似度不是数学等价判定器；本卷不把“未命中规则”称作已确认的新猜想。按整篇论文、同一序列或命名题目族排除会牺牲一些收录率，目的是降低重印前卷内容的风险。

04 来源贡献与新增分布

来源	保留记录数	收录形式
OEIS 官方序列文本	17,579	参见正文中的类型与完整度标记
ETH Randomstrasse 101	18	参见正文中的类型与完整度标记
ConjectureBench 编目	41	参见正文中的类型与完整度标记
OpenConjecture / arXiv	661	参见正文中的类型与完整度标记
MathOverflow	603	参见正文中的类型与完整度标记
Mathematics Stack Exchange	1,034	参见正文中的类型与完整度标记
TOPP 来源定位	3	参见正文中的类型与完整度标记
参数型问题实例	9,342	参数实例，另列附录
Epoch / OEIS 历史定位	42	参见正文中的类型与完整度标记
图论论文定位	372	参见正文中的类型与完整度标记
Bondy-Murty 附录定位	7	参见正文中的类型与完整度标记

EGRES Open 的 95 条候选也参与了扫描，但经本次比对没有作为新条目保留。发现一个新入口，并不意味着里面的问题是前两卷没有的。

本卷没有给出人类猜想总数的新估计：三个文档都是有边界的记录汇编，计数单位和文本完整度并不统一，不能把三个数字直接当成互不相同的数学猜想总量。

05 如何使用本卷

正文采用 V3-000001 等本卷编号；附录采用 V3P-000001。原来源编号、提出者或帖作者、日期、来源链接同时保留。PDF 目录可点击，阅读器书签可快速跳转；全文搜索支持英文题名、OEIS A 编号和论坛问题号。

A 章：明确表述

保留可复用的原始问题段、LaTeX 猜想块或目录整理文本。它们仍可能依赖文章其他部分的定义。来源若只是自动标注为开放，本报告不会把该标注提升为数学界确认的状态。

B 章：历史与当前提及

同一个序列条目中的所有关键词命中段合并为一条，段落顺序按名称、注释、公式分组。正文不复制整个序列页；完整可用字段保存在 PDF 附件，定义、作者更新、相关序列与外链可据此回查。不能把一条序列记录自动等同于一个独立猜想。

C 章：论坛和来源指针

论坛保留问题帖文字，未复制图像或回答，亦未核验是否已被回答推翻。来源指针则只给出论文、源文件行号或书籍位置；它明确缺少正文，不是“完整收集了该数学猜想”的证明。

D 章：参数问题

代码界、覆盖设计、差集和 Ramsey 数的每一组参数可能是一个有意义的开放任务，却未必对应人类单独命名的猜想。附录单列实例数，避免用大量参数行扩张“猜想总量”。数值界限沿用来源观察日，不代表整理日最新最佳界限。

附件 volume3_records_and_audit.zip 收录全部 29,702 条保留资料、完整排除日志、页码映射、归属说明、源文件哈希与筛查脚本。原始 Unicode 和 LaTeX 保留；极少数字形无法显示时，以 [U+编码] 明示，附件保留原字符。

06 来源、署名与内容许可

S1 OEIS Foundation Inc. 与逐条贡献者；官方 oeisdata

https://github.com/oeis/oeisdata

CC BY-SA 4.0。保留逐条来源和作者；将 N/C/F 字段节选并重新编排，属于本卷所作改动。

S2 Robert Davis / OpenConjecture 项目

https://github.com/davisrbr/conjectures-arxiv

猜想抽取和模型标签由该项目提供。正文只刊本轮选定的 CC BY / CC BY-SA 文本；其他项只保留元数据定位。

S3 Anirudha Ramesh、Shreyas Pimpalgaonkar / Bespoke Labs，ConjectureBench

https://github.com/bespokelabsai/conjecture-bench

其原创编目文字 CC BY 4.0；上游材料并未因此重新授权。参数附录保留数值事实和归属，不复制原表格图像、构造或完整文献。

S4 graph-theory-AI / graph-conjectures

https://github.com/graph-theory-AI/graph-conjectures

仅使用论文、作者、问题标签和书页位置等定位信息；抽取集与原论文均可能需要进一步核验。

S5 Epoch / LeanOpenProblems-results

https://github.com/epoch-research/LeanOpenProblems-results

OEIS 提出者、日期与声明名作为历史线索；其模型生成概述不作为新数学证明。

S6 MathOverflow、Mathematics Stack Exchange 的原帖作者

https://api.stackexchange.com/docs/questions

各帖按返回的 content_license 标注 CC BY-SA 版本；保留作者和页面链接。HTML 转为文字，图片与回答未重印。

S7 Randomstrasse 101 研究博客及逐篇作者

https://randomstrasse101.math.ethz.ch/archives/

网页声明 CC BY 4.0；抽取明示的猜想/开放问题块，保留论文与背景的回查入口。

各来源部分仍受各自许可约束，尤其 OEIS 与论坛的 BY-SA 要求；不对整本文档作统一的宽松再许可。封面的“调度 AI 生成”说明指本报告的检索整理与制版，不替代原始数学贡献的署名。

Sequential KV Cache Compression via Probabilistic Language Tries: Beyond the Per-Vector Shannon Limit | KV.tex:1359-1383

\label{conj:cross_session} For sessions s, s' drawn i.i.d.\ from $P_{\mathcal{M}}$, the conditional entropy of session s's KV cache given the cluster centroid s^*'s full cache satisfies: \[H\bigl(\mathrm{KV}_{\leq n}(s) \mid \mathrm{KV}_{\leq n}(s^*)\bigr) \;\leq\; \sum_{i=\bar{d}+1}^{n} H\bigl(t_i^{(s)} \mid t_{<i}^{(s)}\bigr) \;+\; H\bigl(t_{\bar{d}+1}^{(s)} \mid t_{\bar{d}+1}^{(s^*)}, t_{<\bar{d}+1}^{(s)}\bigr), \] where $\bar{d}$ is the divergence position of s and s^*. \emph{Partial proof sketch.} The first term bounds the ``tail'' entropy of session $s$ after divergence: positions $i > \bar{d}$ are bounded by the sequential entropy bound exactly as in Theorem~\ref{thm:seq_bound}. The second term bounds the ``divergence cost'': knowing $t_{\bar{d}+1}^{(s^*)}$ provides partial information about which subtree s is in (via the cluster structure), reducing the entropy of $t_{\bar{d}+1}^{(s)}$. The bound formalizes the

Layer~1 gain: prefix deduplication saves bits on the tail (first term, bounded by per-token surprisal) and reduces divergence cost (second term, bounded by the trie metric $d_{\mathcal{T}}(s, s^*)$). A formal proof requires bounding the conditional mutual information between the centroid's divergence token and the session's divergence token, which depends on the cluster radius δ.

V3-000094 | OC-2127

Sequential KV Cache Compression via Probabilistic Language Tries: Beyond the Per-Vector Shannon Limit | KV.tex:1385-1414

\label{conj:strict_dominance} For any per-vector compression scheme $\mathcal{C}$ (including TurboQuant, KIVI, KVQuant, and all future schemes bounded by the per-vector Shannon limit), there exists a context length $n^*(\mathcal{C})$ such that for all $n > n^*(\mathcal{C})$: \[R_{\mathrm{seq}}(n) \;<\; R_{\mathcal{C}}(n), \] where $R_{\mathrm{seq}}(n)$ is the total bits used by sequential compression and $R_{\mathcal{C}}(n)$ is the total bits used by scheme $\mathcal{C}$, both for a context of length n. \emph{Partial proof.} $R_{\mathcal{C}}(n) \geq B_{\rm pv} \cdot n$ for some $B_{\rm pv} > 0$ (the per-vector Shannon limit is a hard floor for any per-vector scheme). $R_{\mathrm{seq}}(n) = \sum_{i=1}^n H(\mathrm{KV}_i \mid \mathrm{KV}_{<i}) \leq \sum_{i=1}^n H_i$. Under the monotone entropy condition (Corollary~\ref{cor:asymptotic}), $\frac{1}{n}\sum_{i=1}^n H_i = \bar{H}_n \to H_\infty < B_{\rm pv}$ as $n \to \infty$ (since H_∞ is the model's entropy rate, which is strictly less than any fixed per-vector bit budget for a model with perplexity $< 2^{B_{\rm pv}/d_{\rm head}}$). Thus $R_{\mathrm{seq}}(n)/n \to H_\infty < B_{\rm pv} \leq R_{\mathcal{C}}(n)/n$, giving the stated strict dominance for large n. The threshold $n^*(\mathcal{C}) = O(H_\infty / (B_{\rm pv} - H_\infty))$. The main gap in this argument: the monotone entropy condition holds only for coherent text; for mixed-topic sessions with high surprisal variance, $\bar{H}_n$ may not converge below $B_{\rm pv}$. Bounding n^* for realistic session distributions is the key open problem.

V3-000118 | OC-1600

From BV-BFV Quantization to Reshetikhin-Turaev Invariants | RT_paper.tex:1652-1677

\label{conj:main} There exists a natural equivalence of $(3\text{-}2\text{-}1)$-extended topological quantum field theories \begin{equation} Z_{\mathrm{BV,np}}^{(k)} \;\simeq\; Z_{\mathrm{RT}}^{(k)} \;:\; \Bord_3^{\mathrm{ext}} \longrightarrow 2\text{-}\Vect, \end{equation} where $Z_{\mathrm{BV,np}}^{(k)}$ denotes the non-perturbative completion of the BV-BFV partition function at level k and $2\text{-}\Vect$ is the 2-category of $\CC$-linear categories, functors, and natural transformations. At each categorical level, the equivalence identifies: \begin{enumerate}[label=(\roman*)] \item \emph{Circles:} the $\EE_2$-category $\mathcal{B}_{\CS}^{(k)} \simeq \overline{\Rep}_q(G)$ (Conjecture \ref{conj:E2-equiv}); \item \emph{Closed surfaces:} the factorization homology categories $\iint_{\Sigma_g} \overline{\Rep}_q(G) \simeq (\mathbf{H},\, u_{\Sigma_g})$, with $u_{\Sigma_g} = V_{\mathrm{RT}}(\Sigma_g)$ (Theorem \ref{thm:AKZ}); \item \emph{3-cobordisms:} the linear maps between RT state spaces $\Zrt(M): V_{\mathrm{RT}}(\Sigma_1) \to V_{\mathrm{RT}}(\Sigma_2)$. \end{enumerate} More precisely, for every closed oriented surface Σ_g, the BV-BFV state space is identified with the RT state space via the chain \begin{equation*} \begin{tikzcd}[column sep=2.5em, row sep=2.5em] \mathcal{H}_{\Sigma_g}^{\BV} \arrow[d, dashed, leftrightarrow, "\sim"'] & \Quant\big(\Loc_G(\Sigma_g)\big) \arrow[l, "\textnormal{Step 2}"'] \arrow[r, "\sim", "\textnormal{BBJ}"'] & \displaystyle\iint_{\Sigma_g} \Rep_q(G) \arrow[d, "\textnormal{semisimplify}"] \\ V_{\mathrm{RT}}(\Sigma_g) & (\Vect,\, u_{\Sigma_g}) \arrow[l, "u_{\Sigma_g} \,\mapsto"'] \arrow[r, leftarrow, "\sim"', "\textnormal{AKZ}"] & \displaystyle\iint_{\Sigma_g} \overline{\Rep}_q(G) \end{tikzcd} \end{equation*} where the distinguished object u_{Σ_g} is the RT state space $V_{\mathrm{RT}}(\Sigma_g)$. For every oriented 3-dimensional cobordism $M: \Sigma_1 \to \Sigma_2$, the cobordism induces a functor $\iiint_M$ between the factorization homology categories $\iint_{\Sigma_i} \mathcal{B}_{\CS}^{(k)}$. After the identification with $\overline{\Rep}_q(G)$ via Conjecture \ref{conj:E2-equiv}, and the collapse $\iint_{\Sigma_i} \overline{\Rep}_q(G) \simeq (\Vect,\, u_{\Sigma_i})$ via AKZ, this functor induces a linear map between the distinguished objects. The conjecture asserts that this linear map agrees with the RT partition function: \begin{equation}\label{eq:main-diagram} \begin{tikzcd}[column sep=4em] \iint_{\Sigma_1} \overline{\Rep}_q(G) \arrow[r, "\iiint_M"] \arrow[d, "\textnormal{AKZ}"', "\sim"] & \iint_{\Sigma_2} \overline{\Rep}_q(G) \arrow[d, "\sim"', "\textnormal{AKZ}"] \\ (\Vect,\, u_{\Sigma_1} = V_{\mathrm{RT}}(\Sigma_1)) \arrow[r, "\Zrt(M)"'] & (\Vect,\, u_{\Sigma_2} = V_{\mathrm{RT}}(\Sigma_2)) \end{tikzcd} \end{equation} Here the vertical equivalences are given by the Ai--Kong--Zheng theorem (Theorem \ref{thm:AKZ}), applied after identifying $\mathcal{B}_{\CS}^{(k)} \simeq \overline{\Rep}_q(G)$ (Conjecture \ref{conj:E2-equiv}). The top horizontal arrow is the functor on factorization homology categories induced by the cobordism M; the bottom horizontal arrow is the linear map between distinguished objects, which is the RT partition function $\Zrt(M): V_{\mathrm{RT}}(\Sigma_1) \to V_{\mathrm{RT}}(\Sigma_2)$.

V3-000122 | OC-1604

From BV-BFV Quantization to Reshetikhin-Turaev Invariants | RT_paper.tex:1985-1991

\label{conj:koszul} The category of Chern--Simons boundary conditions is equivalent to ind-coherent sheaves on the formal completion of the character stack, i.e., we have \begin{equation} \mathcal{B}_{\CS} \;\simeq\; \IndCoh\big(\Loc_G(M)^{\wedge}\big), \end{equation} where $\IndCoh$ denotes the category of ind-coherent sheaves in the sense of Gaitsgory--Rozenblyum \cite{GR2017} and $\Loc_G(M)^{\wedge}$ is the formal completion of the derived character stack along its classical truncation. Concretely, this means that the BV-BFV partition function around each flat connection determines (and is determined by) the local structure of an ind-coherent sheaf at the corresponding point of the character stack, and the global sheaf encodes all of the perturbative data simultaneously, together with the non-perturbative ``gluing data'' that relates the different perturbative expansions to one another.

Additionally, W_n for $n \in \Z$ are the standard branches of the Lambert-W function \cite[Equation 4.13.1_1]{DLMF}. The asymptotics of the eigenvalues satisfy the ``ILW Weyl law'' \begin{equation} R^\wyl(\zeta_n) = \left(n - \frac{1}{2} \right) \pi \epsilon + \bigO{\epsilon^2} \label{eq:WeylLaw} \end{equation} for $n \in \N$. Defining the tail integrals $\theta_\pm: [1/2\delta, \zeta_{\maxrm}]_{\quadratrix{\delta}} \to \R$ \begin{equation} \theta_\pm(\zeta) := \im{\zeta} x_\pm(\zeta) + \int^{\pm\infty}_{x_\pm(\zeta)} \im{ \zeta + \frac{1}{2 \delta} W_{-1}\left(-2\delta \zeta \ee^{-2\delta(\zeta + u_0(x))}\right)} \, \dd x \, . \label{eq:TailIntegralsDef} \end{equation} Then the norming constants have the asymptotics \begin{align} c_n &= \exp \Bigg(\frac{2}{\epsilon} \theta_+(\zeta_n) \Bigg) \left| \frac{(2 \delta)^2 \zeta_n}{1 -2 \delta \zeta_n} \right| \nonumber \\ &\Quad[2] \times \left(\int_{x_-(\zeta_n)}^{x_+(\zeta_n)} \frac{2\delta W_{-1}(-2\delta \zeta_n \ee^{-2\delta(\zeta_n + u_0(x))})}{1+W_{-1}(-2\delta \zeta_n \ee^{-2\delta(\zeta_n + u_0(x))})} - \frac{2\delta W_0(-2\delta \zeta_n \ee^{-2\delta(\zeta_n + u_0(x))})}{1+W_0(-2\delta \zeta_n \ee^{-2\delta(\zeta_n + u_0(x))})} \, \dd x \right)^{-1} \nonumber \\ &\Quad[2] \times \left(1 + \bigO{\epsilon^{1/6}} \right) \, . \label{eq:NormingConstAsymptoticFormula} \end{align} Finally, the reflection coefficient is small beyond all orders in ϵ.

On the Harris-Viehmann conjecture for Hodge-Newton reducible local Shimura data of abelian type | arxiv.tex:475-485

(Harris--Viehmann conjecture) \cite[Conjecture 8.5]{RapoportViehmann}\label{cnj: HV OG} Fix a prime $\ell \neq p$. Let $(G, [b], \{\mu\})$ be a non-basic unramified local Shimura datum. Let L be a Levi subgroup of G such that $b \in L(\breve{\Q}_p)$ for some $b \in [b]$, and let P be a standard parabolic containing L. Let J_b be an inner form of a Levi subgroup contained in L. Let $I_{b,\{\mu\}, L}$ be the set of $L(\breve{\Z}_p)$-conjugacy classes of L with cocharacter representative μ' such that: \begin{enumerate} \item $\mu' \in \{\mu\}$. \item $[b] \cap L(\breve{\Z}_p)\mu'(p)L(\breve{\Z}_p)$ is non-empty. \end{enumerate} Then for any admissible $\overline{\Q}_\ell$-representation ρ of $J_b(\Q_p)$, the virtual representation of $G(\Q_p)\x \mathcal{W}_E$ is expressed by the following parabolic inductive formula: \begin{align*} \mathrm{H}^\bullet(\RZ^\infty_{G, b})_\rho = \mathrm{Ind}_{P(\Q_p)}^{G(\Q_p)}\Big(\sum_{\{\mu'\}\in I_{b,\{\mu\}, L}}\mathrm{H}^\bullet(\RZ^\infty_{L, b})_\rho \Big). \end{align*}

On the Argument of the Lerch, Chowla--Selberg Formula and CM Values of $η(τ)$ | etacm2.tex:412-433

Let $\tau=(-b+\sqrt{D})/(2a)$ with $D=b^2-4ac<0$, where as usual $a>0$ and $\gcd(a,b,c)=1$, and write $D=D_0f^2$ with D_0 fundamental. As above, set $$\al(\tau)=\dfrac{\eta(\tau)^4}{a\cdot c(D_0,f)\CS(D_0)/(2\pi D)}$$ and let $\be(\tau)$ as in the above definition. \begin{enumerate} \item The numbers $a\cdot\al(\tau)$ and $a/\al(\tau)$ are algebraic \emph{integers}. \item The norm of $\al(\tau)$ as an algebraic number (i.e., the product of its algebraic conjugates) is equal to ±1 (since it is usually not an algebraic integer, this of course does not mean that it is a unit), and in fact perhaps always equal to 1. \item Write $h(D)=2^vm$ with m odd. The minimal polynomial of $a\cdot\be(\tau)$ is of the form $B(x^{jm})$ with $j=1$ if $v=0$, and $j\mid3\cdot2^{v-1}$ if $v\ge1$, and where the degree of B is equal to $h(D)$ if $a=1$ and to $h(D)$ or $2h(D)$ if $a>1$. \item The number $\al(\tau)^{\lcm(6,h(D))}$ belongs to the ring class field of the quadratic order of discriminant D, of degree $2h(D)$, and when $b=0$ or $a=b$ it even belongs to its subfield of degree $h(D)$ fixed by the automorphism $\sqrt{D}\mapsto-\sqrt{D}$. \end{enumerate}

Sharp Spectral Thresholds for Multi-View Spiked Wigner Models | draft.tex:3238-3257

We conjecture that this choice of AMP algorithm will converge to equilibrium, as $t\to\infty$. By equilibrium, we mean the following two statements: \begin{enumerate} \item The state evolution parameters converge $q_t \to q_{\ast}\in\RR^L$, where $q_{\ast}$ is the solution to the following fixed-point equation \begin{equation} q_{\ast} = 1 - \diag\sbr{\rbr{\Diag\rbr{\lambda\odot q_{\ast}}+B^{-1}}^{-1}}. \end{equation} In comparison with our self-consistent equations \eqref{eq: self-consistent eq matrix}, it holds that $q_{\ast}^{(l)}=1-M_{ll}(1)$. \item Let $m_t\in\RR^{nL}$ be the concatenation of $m_t^{(1)},\ldots,m_t^{(L)}$. Then it also converges to equilibrium, as $m_t\to m_{\ast}\in\RR^{nL}$, where $m_{\ast}$ satisfies that \begin{equation}\label{eq:AMP variable equilibrium} m_{\ast}^{(l)}=\sqrt{\frac{\lambda_l}{n}} A^{(l)} \cE_\ast^{(l)}(m_{\ast})-\lambda_l\rbr{1-q_{\ast}^{(l)}}\cE_\ast^{(l)}(m_{\ast}), \end{equation} where we use $\cE_{\ast}$ to denote the denoiser with the limiting state evolution parameters $q_{\ast}$. Moreover, we have the following distributional result \begin{equation}\label{eq:AMP distributional} m_{\ast}^{(l)} \overset{d.}{\approx} \lambda_lq_{\ast}^{(l)} X^{(l)}+\sqrt{\lambda_l q_{\ast}^{(l)}}\cN(0,I_n),\quad l\in[L]. \end{equation} Moreover, we also have $X^{(l)\top}\cE^{(l)}_\ast\rbr{m_{\ast}}/n \overset{d.}{\approx} q_{\ast}^{(l)}$. \end{enumerate}

Spectral Intertwining Operators | main.tex:3414-3461

\label{categorical} Let $G = (G^*)_b$ be as above. For a fixed Whittaker datum of G^*, there is an equivalence of categories \[\widetilde{\operatorname{LL}}_{G^*} \colon D_{\text{lis}}(\operatorname{Bun}_{G^*})^\omega \simeq D\Coh^{\text{qc}}(\Par_{G^\vee}), \] where ω denotes the full subcategory of compact object and qc denotes the full subcategory of objects with compact supports, satisfying the following properties: \begin{enumerate} \item Under this functor, the parabolic induction operator corresponds to the Eisenstein operator. More precisely, let P be a parabolic subgroup of G with Levi subgroup M, denote by $\bar{P}$ the opposite parabolic subgroup of P. We have $M=(M^*)_b$ for the quasi-split inner form M^* of M and the Whittaker datum for G induces a Whittaker datum for M^*. Then the diagram \[\begin{tikzcd} D(\mathsf{Rep}(M(F))) & D_{\text{lis}}(\operatorname{Bun}_{M^*})^\omega & D\Coh^{\text{qc}}(\Par_{M^\vee}) \\ D(\mathsf{Rep}(G(F))) & D_{\text{lis}}(\operatorname{Bun}_{G^*})^\omega & D\Coh^{\text{qc}}(\Par_{G^\vee}) \arrow["i_{b!}",from=1-1, to=1-2] \arrow["\widetilde{\operatorname{LL}}_{M^*}",from=1-2, to=1-3] \arrow["i_{b!}",from=2-1, to=2-2] \arrow["\widetilde{\operatorname{LL}}_{G^*}",from=2-2, to=2-3] \arrow["{i_{\bar{P}}^G}"', from=1-1, to=2-1] \arrow["{\Eis^a_{\bar{P}!}}", from=1-2, to=2-2] \arrow["{\Eis_{P^\vee}}", from=1-3, to=2-3] \end{tikzcd} \] commutes up to isomorphisms, where $\Eis^a_{\bar{P}!}$ is the Eisenstein operator for Bun's, defined in \cite{hamann}, Definition 2.1.8. In this notation, ``$a$'' stands for ``automorphic side''. \item This functor is compatible with automorphisms: for an automorphism σ of G^* that preserves b and a pinning, it induces an isomorphism $\sigma^\vee$ of $G^\vee$. Then the diagram \[\begin{tikzcd} D(\mathsf{Rep}(G(F))) & D_{\text{lis}}(\operatorname{Bun}_{G^*})^\omega & D\Coh^{\text{qc}}(\Par_{G^\vee}) \\ D(\mathsf{Rep}(G(F))) & D_{\text{lis}}(\operatorname{Bun}_{G^*})^\omega & D\Coh^{\text{qc}}(\Par_{G^\vee}) \arrow["i_{b!}",from=1-1, to=1-2] \arrow["\widetilde{\operatorname{LL}}_{G^*}",from=1-2, to=1-3] \arrow["i_{b!}",from=2-1, to=2-2] \arrow["\widetilde{\operatorname{LL}}_{G^*}",from=2-2, to=2-3] \arrow["\sigma"', from=1-1, to=2-1] \arrow["\sigma", from=1-2, to=2-2] \arrow["\sigma^\vee", from=1-3, to=2-3] \end{tikzcd} \] commutes up to isomorphisms. Such a functor is called categorical local Langlands correspondence. \item The correspondence is compatible with the Kottwitz isomorphism. More precisely, for any $V \in \mathsf{Rep}(G(F))$, The $Z(G^\vee)^{W_F}$-character of the fiber of $\widetilde{\operatorname{LL}}_{G^*} \circ i_{b!}(V)$ at any point in $\Par_{G^\vee}$ is $\kappa(b)$ under the Kottwitz isomorphism $\kappa\colon B(G^*)_{bas} \simeq X^*(Z(G^\vee)^{W_F})$. \end{enumerate}

V3-000329 | OEIS-A000041

a(n) is the number of partitions of n (the partition numbers).

Conjecture: starting with offset 1 represents the numbers of ordered compositions of n using the signed (++--++...) terms of A001318 starting (1, 2, -5, -7, 12, 15, ...). - _Gary W. Adamson_, Apr 04 2013 (this is true by the pentagonal number theorem, _Joerg Arndt_, Apr 08 2013) Conjecture: No a(n) has the form x^m with m > 1 and x > 1. - _Zhi-Wei Sun_, Dec 02 2013 Conjecture: Each integer n > 2 different from 6 can be written as a sum of finitely many numbers of the form a(k) + 2 (k > 0) with no summand dividing another. This has been verified for n <= 7140. - _Zhi-Wei Sun_, May 16 2023 G.f.: (conjecture) (r(x) * r(x^2) * r(x^4) * r(x^8) * ...) where r(x) is A000009: (1, 1, 1, 2, 2, 3, 4, ...). - _Gary W. Adamson_, Sep 18 2016; _Doron Zeilberger_ observed today that "This follows immediately from Euler's formula 1/(1-z) = (1+z)*(1+z^2)*(1+z^4)*(1+z^8)*..." _Gary W. Adamson_, Sep 20 2016

V3-000331 | OEIS-A000048

Number of n-bead necklaces with beads of 2 colors and primitive period n, when turning over is not allowed but the two colors can be interchanged.

Conjecture: Also the number of caliber-n cycles of Zagier-reduced indefinite binary quadratic forms with sum invariant equal to s, where (s-1)/n is an odd integer. - _Barry R. Smith_, Dec 14 2014 The comment above is true for discriminants of the form a^2+4 (as Smith stated it, Conjecture 7 of his paper). Proved by an explicit bijection that turns kneading into the cyclic rotation of binary words of odd weight; Smith's Conjecture 6 is also proved in full (see link). - _Roberto Blanco Gómez_, Oct 07 2026

V3-000332 | OEIS-A000071

a(n) = Fibonacci(n) - 1.

We can establish _Gerald McGarvey_'s conjecture mentioned in the Formula section, however we require n > 4. We need the following 4 prerequisites. (1) a(n) = F(n) - 1, with {F(n)}_{n >= 1} the Fibonacci numbers A000045. (2) (Binet form) F(n) = (d^n - e^n)/sqrt(5) with d = phi and e = 1 - phi, de = -1 and d + e = 1. It follows that a(n) = (d(n) - e(n))/sqrt(5) - 1. (3) To prove floor(x) = y is equivalent to proving that x - y lies in the half-open interval [0, 1). (4) The series {s(n) = c1 x^n + c2}_{n >= 1}, with -1 < x < 0, and c1 and c2 positive constants, converges by oscillation with s(1) < s(3) < s(5) < ... < s(6) < s(4) < s(2). If follows that for any odd n, the open interval (s(n), s(n+1)) contains the subsequence {s(t)}_{t >= n + 2}. Using these prerequisites we can analyze the conjecture. Conjecture: for k a positive odd integer, the sequence {a(k^n): n >= 1} is a strong divisibility sequence; that is, for n, m >= 1, gcd(a(k^n), a(k^m)) = a(k^gcd(n,m)). - _Peter Bala_, Dec 05 2022 Conjecture: for all c such that 2*(2 - Phi) <= c < (2 + Phi)*(2 - Phi) we have a(n) = floor(Phi*a(n-1) + c) for n > 4. - _Gerald McGarvey_, Jul 22 2004. This is true provided n > 3 is changed to n > 4, see proof in Comments section. - _Russell Jay Hendel_, Mar 15 2015

V3-000335 | OEIS-A000110

Bell or exponential numbers: number of ways to partition a set of n labeled elements.

When n is prime, a(n) == 2 (mod n), but the converse is not always true. Define a Bell pseudoprime to be a composite number n such that a(n) == 2 (mod n). W. F. Lunnon recently found the Bell pseudoprimes 21361 = 41*521 and C46 = 3*23*16218646893090134590535390526854205539989357 and conjectured that Bell pseudoprimes are extremely scarce. So the second Bell pseudoprime is unlikely to be known with certainty in the near future. I confirmed that 21361 is the first. - _David W. Wilson_, Aug 04 2007 and Sep 24 2007 Conjecture: No a(n) has the form x^m with m > 1 and x > 1. - _Zhi-Wei Sun_, Dec 02 2013

V3-000355 | OEIS-A000217

Triangular numbers: a(n) = binomial(n+1,2) = n*(n+1)/2 = 0 + 1 + 2 + ... + n.

Conjecturally, 1, 6, 120 are the only numbers that are both triangular and factorial. - Christopher M. Tomaszewski (cmt1288(AT)comcast.net), Mar 30 2005 Conjecture: For n > 0, there is always a prime between A000217(n) and A000217(n+1). Sequence A065383 has the first 1000 of these primes. - _Ivan N. Ianakiev_, Mar 11 2013 Conjecture: the sequence is the genus/deficiency of the sinusoidal spirals of index n which are algebraic curves. The value 0 corresponds to the case of the Bernoulli Lemniscate n=2. So the formula conjectured is (n-1)(n-2)/2. - _Wolfgang Tintemann_, Aug 02 2015 Conjecture: Let m be any positive integer. Then, for each n = 1,2,3,... the set {Sum_{k=s..t} 1/k^m: 1 <= s <= t <= n} has cardinality a(n) = n*(n+1)/2; in other words, all the sums Sum_{k=s..t} 1/k^m with 1 <= s <= t are pairwise distinct. (I have checked this conjecture via a computer and found no counterexample.) - _Zhi-Wei Sun_, Sep 09 2015

V3-000357 | OEIS-A000241

Crossing number of complete graph with n nodes.

It was conjectured by A. Hill in 1958 (see Guy 1960 and Harary-Hill 1963) that a(n) = floor(n/2)*floor((n-1)/2)*floor((n-2)/2)*floor((n-3)/2)/4 (see A028723). This is also sometimes referred to as Guy's conjecture. - _N. J. A. Sloane_, Jan 21 2015 Another version of the conjecture is that a(n)=C(floor(n/2),2)*C(floor((n-1)/2),2). We conjecture that this sequence is also given by one half of the third coefficient of the denominator polynomial of the n-th convergent to the g.f. of n!. From the Pan and Richter reference: 0.8594 Z(n) <= a(n) <= Z(n), where Z(n) is the conjectured formula (Richter and Thomassen 1997, de Klerk et al. 2007). - _Danny Rorabaugh_, Mar 12 2015 Empirical g.f.: -x^5*(1+x+x^2)/(x+1)^3/(x-1)^5, which is the same as the conjectured formula of A. Hill. - _Simon Plouffe_, Feb 06 2013

V3-000379 | OEIS-A000531

From area of cyclic polygon of 2n + 1 sides.

A conjectured definition: Let 0 < a_1 < a_2 <...<a_{2n} < 1. Then how many ways are there in which one can add or subtract all the a_i to get an odd number. For example, take n = 2. Then the options are a_1+a_2+a_3+a_4 = 1 or 3; one can change the sign of any of the a_i's and get 1; or -a_1-a_2+a_3+a_4 = 1. That's a total of 7, which is the 2nd number of this sequence. One of the definitions of the sequence (which was how I came across it) is the degree of the equation giving the area of a cyclic polygon in terms of the sides. I conjectured that for any set of side lengths there is a unique way of fitting them together for any possible winding number and any possible subset of sides which go round the circle in a retrograde manner. - Simon Norton (simon(AT)dpmms.cam.ac.uk), May 14 2001 a(n) is also the number of walks of length 2n in the quarter plane starting and ending at the origin using steps {(1,1),(1,0),(-1,0),(-1,-1)} (which appear in Gessel's conjecture) in which the steps (1,0) and (-1,0) appear exactly once each. - _Arvind Ayyer_, Mar 02 2009 (Conjecture) a(n)=2^(2*n)*sum_{k=1..n} cos(k*Pi/(2*n+1))^2*n. - _L. Edson Jeffery_, Jan 21 2012

V3-000383 | OEIS-A000698

A problem of configurations: a(0) = 1; for n>0, a(n) = (2n-1)!! - Sum_{k=1..n-1} (2k-1)!! a(n-k). Also the number of shellings of an n-cube, divided by 2^n n!.

The o.g.f. B(x) = Sum_{n>=1} a(n)*x^(2*n-1) = x + 2*x^3 + 10*x^5 + 74*x^7 + ... satisfies the Riccati differential equation y'(x) = -1/x^2 + (1/x^3)*y(x) - (1/x^2)*y(x)^2 with initial condition y(0) = 0 (cf. A005412). The solution is B(x) = 1/z(x) + 1/x, where z(x) = -Sum_{n>=0} A001147(n) * x^(2*n+1) = -(x + x^3 + 3*x^5 + 15*x^7 + ...). The function b(x) = -B(1/x) satisfies b'(x) = -1 - (x + b(x))*b(x). Hence the differential operator (D^2 + x*D + 1), where D = d/dx, factorizes as (D - a(x))*(D - b(x)), where a(x) = -(x + b(x)), as conjectured by [Edgar, Problem 4.32]. For a refinement of this sequence see A053979. (End)

V3-000386 | OEIS-A000727

Expansion of Product_{k >= 1} (1 - x^k)^4.

Ramanujan (see the link, pp. 155 and 157 Nr. 23.) conjectured the expansion coefficients called Psi_4(n) of eta^4(6*z) in powers of q = exp(2*Pi*i*z), Im(z) > 0, where i is the imaginary unit. In the Finch link on p. 5, multiplicity is used and Psi_4(p^r), called f(p^r), is given (see also b(p^e) formula given by Michael Somos, Aug 23 2006). Mordell proved this conjecture on pp. 121-122 based on Klein-Fricke, Theorie der elliptischen Modulfunktionen, 1892, Band II, p. 374. The product formula for the Dirichlet series, Mordell, eq. (7) for a=2,is used to find Psi_4(n), called f_2(n), from f_2(p) for primes p. The primes p = 2 and 3 do not appear in the product. - _Wolfdieter Lang_, May 03 2016

V3-000401 | OEIS-A000984

Central binomial coefficients: binomial(2*n,n) = (2*n)!/(n!)^2.

Erdős, Graham et al. conjectured that a(n) is never squarefree for sufficiently large n (cf. Graham, Knuth, Patashnik, Concrete Math., 2nd ed., Exercise 112). Sárközy showed that if s(n) is the square part of a(n), then s(n) is asymptotically (sqrt(2)-2) * (sqrt(n)) * zeta(1/2). Granville and Ramare proved that the only squarefree values are a(1)=2, a(2)=6 and a(4)=70. - _Jonathan Vos Post_, Dec 04 2004 [For more about this conjecture, see A261009. - _N. J. A. Sloane_, Oct 25 2015] The MathOverflow link contains the following comment (slightly edited): The Erdős squarefree conjecture (that a(n) is never squarefree for n>4) was proved in 1980 by Sárközy, A. (On divisors of binomial coefficients. I. J. Number Theory 20 (1985), no. 1, 70-80.) who showed that the conjecture holds for all sufficiently large values of n, and by A. Granville and O. Ramaré (Explicit bounds on exponential sums and the scarcity of squarefree binomial coefficients. Mathematika 43 (1996), no. 1, 73-107) who showed that it holds for all n>4. - Fedor Petrov, Nov 13 2010. [From _N. J. A. Sloane_, Oct 29 2015] Straub, Amdeberhan and Moll: "... it is conjectured that there are only finitely many indices n such that C_n is not divisible by any of 3, 5, 7 and 11." - _Jonathan Vos Post_, Nov 14 2008 Conjecture: For any positive integer n, the polynomial Sum_{k=0}^n a(k)x^k is irreducible over the field of rational numbers. In general, for any integer m>1 and n>0, the polynomial f_{m,n}(x) = Sum_{k=0..n} (m*k)!/(k!)^m*x^k is irreducible over the field of rational numbers. - _Zhi-Wei Sun_, Mar 23 2013 Number of vertices of the subgraph of the (2n-1)-dimensional hypercube induced by all bitstrings with n-1 or n many 1s. The middle levels conjecture asserts that this graph has a Hamilton cycle. - _Torsten Muetze_, Feb 11 2019

V3-000403 | OEIS-A001006

Motzkin numbers: number of ways of drawing any number of nonintersecting chords joining n (labeled) points on a circle.

Conjecture: (2/n)*Sum_{k=1..n} (2k+1)*a(k)^2 is an integer for each positive integer n. - _Zhi-Wei Sun_, Nov 16 2017 The Rubey and Stump reference proves a refinement of a conjecture of René Marczinzik, which they state as: "The number of 2-Gorenstein algebras which are Nakayama algebras with n simple modules and have an oriented line as associated quiver equals the number of Motzkin paths of length n." - _Eric M. Schmidt_, Dec 16 2017 Conjecture: If p is a prime of the form 6m+1 (A002476), then a(p-2) is divisible by p. Currently, no counterexample exists for p < 10^7. Personal communication from _Robert Gerbicz_: mod such p this is equivalent to A066796 with comment: "Every A066796(n) from A066796((p-1)/2) to A066796(p-1) is divisible by prime p of form 6m+1". - _Serge Batalov_, Feb 08 2022 The conjecture is proved in the 2017 paper by Rob Burns in the Links below. The result is contained in Tables 4 and 5 of the paper, which show that a(p-2) == 0 (mod p) when p == 1 (mod 6) and a(p-2) == -1 (mod p) when p == -1 (mod 6). The 2024 paper by Nadav Kohen also proves the conjecture. Proposition 6 of the paper states that a prime p divides a(p-2) if and only if p = (1 mod 3). (End) Conjectures: (1) For prime p == 1 (mod 6) and n, r >= 1, a(n*p^r - 2) == -A005717(n-1) (mod p), where we take A005717(0) = 0 to match Batalov's conjecture above. Let b(n) = 1 for n <= 1, otherwise b(n) = Sum_{k=2..n} b(k-1) * b(n-k), then a(n) = b(n+1) (conjecture). - _Joerg Arndt_, Jan 16 2023 Arndt's conjecture is true (see Fried link). - _Sela Fried_, Dec 01 2025

V3-000418 | OEIS-A001110

Square triangular numbers: numbers that are both triangular and square.

Conjecture: No a(2^k), where k is a nonnegative integer, can be expressed as a sum of a positive square number and a positive triangular number. - _Ivan N. Ianakiev_, Sep 19 2012 For n=2k, k > 0, a(n) is divisible by 12 and is therefore abundant. I conjecture that for n=2k+1 a(n) is deficient [true for k up to 43 incl.]. - _Ivan N. Ianakiev_, Sep 30 2014 The conjecture is true for all k > 0 because: For n=2k+1, k > 0, a(n) is odd. If a(n) is a prime number, it is deficient; otherwise a(n) has one or two distinct prime factors and is therefore deficient again. So for n=2k+1, k > 0, a(n) is deficient. - _Muniru A Asiru_, Apr 13 2016 The conjecture of Sep 19 2012 is false, since a(16) = 98286503002057414584576 = 303363259914^2 + (111868096760*111868096761)/2. This term is A218273(11). For k = 0, 1, 2, 3 there is no such representation, so k = 4 gives the smallest counterexample. - _Clément Garrot_, Aug 25 2026

V3-000426 | OEIS-A001292

Concatenations of cyclic permutations of initial positive integers.

In 1996, Kenichiro Kashihara conjectured that there is no prime power of an integer (A093771) belonging to this sequence (disregarding the trivial case 1); a direct search from 12 to a(100128) has confirmed the conjecture up to 10^1035. There are no perfect powers among terms t which are permutations of 123_...(m - 1)_m for m == {2, 3, 5, 6} (mod 9). This is since 10 == 1 (mod 9) and also (1 + 0) == 1 (mod 9), so digit position has no effect. Hence, t == A134804(m) (mod 9). Now, if m is such that A134804(m) = {3, 6}, there is a lone factor of 3, which is not a perfect power (indeed).

V3-000438 | OEIS-A001519

a(n) = 3*a(n-1) - a(n-2) for n >= 2, with a(0) = a(1) = 1.

Proof: (M_2)^2 = 3*M + 1_2 (with the 2 X 2 unit matrix 1_2) from the characteristic polynomial of M_2 (see a comment in A322602) and the Cayley-Hamilton theorem. The recurrence M^n = M*M^(n-1) leads to (M_n)^n = S(n, 3)*1_2 + S(n-a, 3)*(M - 3*1_2), for n >= 0, with S(n, 3) = F(2(n+1)) = A001906(n+1). Hence ((M_2)^n)[1,1] = S(n, 3) - 2*S(n-1, 3) = a(n) = F(2*n-1) = (1/(2*r+1))*r^(2*n-1)*(1 + (1/r^2)^(2*n-1)), with r = rho(5) = A001622 (golden ratio) (see the first Aug 31 2004 formula, using the recurrence of S(n, 3), and the _Michael Somos_ Oct 28 2002 formula). This proves a conjecture of _Gary W. Adamson_ in A322602.

V3-000475 | OEIS-A002063

a(n) = 9*4^n.

These are squares that can be expressed as sum of exactly two distinct powers of two. For instance, a(4) = 9*4^4 = 2304 = 2^11 + 2^8 . It is conjectured that these are the only squares with this characteristic (tested on squares up to (10^7)^2). - _Andres Cicuttin_, Apr 23 2016 Conjecture is true. It is equivalent to prove that the Diophantine equation m^2 = 2^k*(1+2^h), where h>0, has solutions only when h=3. Dividing by 2^k we must obtain an odd square on the left, since 1+2^h is odd, so we can write (2*r+1)^2 = 1+2^h. Expanding, we have 4*r*(r+1) = 2^h, from which it follows that r must be equal to 1 and thus h=3, since r and r+1 must be powers of 2. - _Giovanni Resta_, Jul 27 2017

V3-000478 | OEIS-A002093

Highly abundant numbers: numbers k such that sigma(k) > sigma(m) for all m < k.

Conjecture: (a) Every highly abundant number > 10 is practical (A005153). (b) For every integer k there exists A such that k divides a(n) for all n > A. Daniel Fischer proved that every highly abundant number greater than 3, 20, 630 is divisible by 2, 6, 12 respectively. The first conjecture has been verified for the first 10000 terms. - _Jaycob Coleman_, Oct 16 2013 Conjecture: For each term k: (1) Let p be the largest prime less than k (if one exists) and let q be the smallest prime greater than k; then k-p is either 1 or a prime, and q-k is either 1 or a prime. (2) The closest prime number p < k located to a distance d = k-p > 1 is also always at a prime distance. These would mean that the even highly abundant numbers greater than 2 always have at least a Goldbach pair of primes. h=p+d. Both observations verified for the first 10000 terms. - _David Morales Marciel_, Jan 04 2016

Number of transitive permutation groups of degree n.

It is conjectured that this is the number of Galois groups for irreducible polynomials of order n. (All such Galois groups are transitive.) - _Charles R Greathouse IV_, May 28 2014 Let G be a transitive permutation groups of degree n. Then G occurs as a Galois group for an irreducible polynomial of degree n with coefficients K if and only if K admits a Galois extension with Galois group G. ("=>" is true by definition of the Galois group for an irreducible polynomial; for "<=", see user631's answer in the Math Overflow link). Hence the conjecture above is equivalent to the inverse Galois problem. Every finite group can be realized as a Galois group of some extension L/K, but for a fixed base field K (for example, K = Q is the field of rational numbers) the question is usually open. - _Jianing Song_, May 26 2025

V3-000484 | OEIS-A002114

Glaisher's H' numbers.

Conjecture: more generally, reducing the sequence modulo a positive integer k produces an eventually periodic sequence with period dividing phi(k). For example, modulo 13 the sequence becomes [1, 11, 2, 5, 7, 0, 1, 11, 2, 5, 7, 0, 1, 11, 2, 5, 7, 0, ...], with an apparent period of 6 = phi(13)/2. Cf. A000364 and A000436. [The conjecture is true when k = p is a prime since the congruence a(n+p-1) == a(n) (mod p) holds for all n >= 1. Cf. A215066. - _Peter Bala_, Oct 13 2026] (End) Conjectural e.g.f.: Sum_{n >= 1} (-1)^n*Product_{k = 1..n} (1 - exp(A007310(k)*z)) = z + 11*z^2/2! + 301*z^3/3! + ... - _Peter Bala_, Dec 09 2021

V3-000517 | OEIS-A002720

Number of partial permutations of an n-set; number of n X n binary matrices with at most one 1 in each row and column.

Conjecture: a(n)*k is the sum of the largest parts in all integer partitions containing their own first differences with n + 1 parts and least part k. - _John Tyler Rascoe_, Feb 28 2024 The conjecture is true. Let k = x_0 < ... < x_n be such a partition. For each i>0 there exists a unique j in [0..i-1] so that x_i = x_{i-1} + x_j. Conversely, each choice of the j's recursively determines an admissible partition, so there are n! such partitions. Let b(n) be the mean of x_n/k over these partitions. Then b(0) = 1 and b(n) = b(n-1) + (1/n) * Sum_{j=0..n-1} b(j), which is the recurrence given below for b(n) = a(n)/n!. Hence the sum of the largest parts is n!*E(x_n) = n!*k*b(n) = k*a(n). - _David Radcliffe_, Jul 20 2026 Asymptotically, a(n)/n! ~ (1/2)*Pi^(-1/2)*exp(-1/2 + 2*n^(1/2))/n^(1/4) and so a(n) ~ C*Bessell(0, 2*sqrt(n))*n! with C = exp(-1/2) = 0.6065306597126334236... - Alec Mihailovs, Sep 06 2005, establishing a conjecture of _Franklin T. Adams-Watters_

V3-000520 | OEIS-A002804

(Presumed) solution to Waring's problem: g(n) = 2^n + floor((3/2)^n) - 2.

It is known (Kubina and Wunderlich, 1990) that g(n) = 2^n + floor((3/2)^n) - 2 for all n <= 471600000. This formula is conjectured to be correct for all n (see A174420). This sequence (which corresponds to Waring's original conjecture) is much easier to compute than A079611, the problem of finding the minimal s = G(n) for almost all (= sufficiently large) integers. See Wikipedia for a one-line proof that this value for g(n), conjectured by J. A. Euler in 1772, is indeed a lower bound; it is known to be tight if 2^n*frac((3/2)^n) + floor((3/2)^n) <= 2^n, and no counterexample to this inequality is known. - _M. F. Hasler_, Jun 29 2014

V3-000526 | OEIS-A002865

Number of partitions of n that do not contain 1 as a part.

Conjecture: Also the number of integer partitions of n - 1 that have a consecutive subsequence summing to each positive integer from 1 to n - 1. For example, (32211) is such a partition because we have consecutive subsequences: There is a sufficient and necessary condition to characterize the partitions defined by Gus Wiseman. It is that the largest part must be less than or equal to the number of ones plus one. Hence, the number of partitions of n with no part greater than the number of ones is the same as the number of partitions of n-1 that have a consecutive subsequence summing to each integer from 1 to n-1. Gus Wiseman's conjecture can be proved bijectively. - _Andrew Yezhou Wang_, Dec 14 2019

V3-000533 | OEIS-A003001

Smallest number of multiplicative persistence n.

For any multiplicative persistence, except multiplicative persistence 2, the set of class representative numbers with that multiplicative persistence is conjectured to be finite. It is observed from this that for the reduced numbers with multiplicative persistence 1, the primes 11, 13, 17 and 19, will not occur in any trajectory of another (larger) number; i.e., all numbers represented by the reduced numbers 11, 13, 17 and 19 have a prime factor of at least 11 (conjectured from the observations). In fact all trajectories can be projected to a trajectory in one of the ten trees with reduced numbers with roots 0..9, and the numbers represented by the reduced number of each leaf have a prime factor of at least 11 (as conjectured from the observations).

V3-000565 | OEIS-A003558

Least number m > 0 such that 2^m == +-1 (mod 2n + 1).

Start a sequence with numbers 1 and n. For next numbers, add previous numbers going backwards until the sum is even. Then the new number is sum/2. I conjecture that the sequence returns to 1,n and a(n) is the cycle length. Proof of the above conjecture: Let n = -1/2; thus 2n + 1 = 0, so operations are performed mod (2n + 1). When the member is even, it is divided by 2. When it is odd, multiply by n, so effectively divide by -2. This is all well-defined in the sense that new members m are 1 <= m <= n. Now see what happens starting from an odd member m. The next member is -m/2. As long as there are even members, divide by 2 and end up with an odd -m/(2^k). Now add all the members starting with m. The sum is m/(2^k). It's divided by 2, so the next member is m/(2^(k+1)). That is the same as (-m/(2^k))/(-2), as with the definition. Conjecture of Kappraff and Adamson in "Polygons and Chaos", p. 13 Section 7, "Chaos and Number": Given the cycle length for N = 2n + 1, the same cycle length is present in bases 4, 9, 16, 25, ..., m^2, for the expansion of 1/N.

V3-000574 | OEIS-A003989

Triangle T from the array A(x, y) = gcd(x,y), for x >= 1, y >= 1, read by antidiagonals.

Imagine a torus having regular polygonal cross-section of m sides. Now, break the torus and twist the free ends, preserving rotational symmetry, then reattach the ends. Let n be the number of faces passed in twisting the torus before reattaching it. For example, if n = m, then the torus has exactly one full twist. Do this for arbitrary m and n (m > 1, n > 0). Now, count the independent, closed paths on the surface of the resulting torus, where a path is "closed" if and only if it returns to its starting point after a finite number of times around the surface of the torus. Conjecture: this number is always gcd(m,n). NOTE: This figure constitutes a group with m and n the binary arguments and gcd(m,n) the resulting value. Twisting in the reverse direction is the inverse operation, and breaking & reattaching in place is the identity operation. - _Jason Richardson-White_, May 06 2013

V3-000601 | OEIS-A004737

Concatenation of sequences (1,2,...,n-1,n,n-1,...,1) for n >= 1.

Let U_1(t)=1, U_2(t)=2*t, and U_r(t)=2*t*U_(r-1)(t)-U(r-2)(t), r>2, be Chebyshev polynomials of the second kind. For q>1 an integer, let N=2*q and x_k=cos((2*k-1)*Pi/N), and define the ordered column vectors V_k=[U_k(x_1), U_k(x_2), ..., U_k(x_q)]^T, k=1,...,q, where A^T denotes the transpose of matrix A. Let E_N=[V_1, V_2, ..., V_q] be the q X q matrix formed from the ordered components of the V_k. E_N contains the joint spectra of the Danzer basis (see [Jeffery]) associated with N. Let M_N=(1/q)*[E_N]^T*E_N. For the trivial case q=1, let M_2=[1]. CONJECTURE: E_N and M_N are always integral and symmetric, with M_N having diagonal entries {1,2,...} beginning at entries 1,j (j odd) in the first row and i,1 (i odd) in the first column and with zeros elsewhere. If N is allowed to increase without bound, and assuming the conjecture is true, then triangle A004737 emerges in its entirety from the successive antidiagonals containing those entries [M_N]_(i,j) such that i+j=2*v, for each v in {1,2,...,floor((q+1)/2)}. For example, for N=18 and q=9 (omitting the zeros for clarity),

V3-000606 | OEIS-A005007

Number of cubic (i.e., regular of degree 3) generalized Moore graphs with 2n nodes.

A generalized Moore graph is a regular graph of degree r where the counts of vertices at each distance from any vertex are 1, r, r(r-1), r(r-1)^2, r(r-1)^3, ... with the last distance having every other vertex. That is, all the levels are full except possibly the last which must have the rest. Alternatively, the girth is as great as the naive bound allows and the diameter is as little as the naive bound allows. Or, the average distance between pairs of vertices achieves the naive lower bound. As far as I know, it is an open problem if there are infinitely many generalized Moore graphs of each degree. - _Brendan McKay_, Oct 06 2003

V3-000639 | OEIS-A005408

The odd numbers: a(n) = 2*n + 1.

Conjecture on primes with one coach (A216371) relating to the odd integers: iff an integer is in A216371 (primes with one coach either of the form 4q-1 or 4q+1, (q > 0)); the top row of its coach is composed of a permutation of the first q odd integers. Example: prime 19 (q = 5), has 5 terms in each row of its coach: 19: [1, 9, 5, 7, 3] ... [1, 1, 1, 2, 4]. This is interpreted: (19 - 1) = (2^1 * 9), (19 - 9) = (2^1 * 5), (19 - 5) = (2^1 - 7), (19 - 7) = (2^2 * 3), (19 - 3) = (2^4 * 1). - _Gary W. Adamson_, Sep 09 2012

V3-000648 | OEIS-A005522

a(n) = 1 + L(n) + F(2*n-1) with {L(n)}_{n>=0} the Lucas numbers (A000032) and F(2*n-1)_{n>=0} the bisected Fibonacci numbers (A001519).

(Comment VI) We can now comment on the g.f., P(x), conjectured by _Simon Plouffe_ and mentioned in the MAPLE section below. Expanding P(x) as a series, we obtain the following g.f. of the a(n): 3 + 6x + 10x^2 + 21x^3 ... . In fact, it is easily checked that P(x) = 1/x (A(x)-4). This settles the Plouffe conjecture as follows: (i) A(x) is the rational function g.f. of a(n)_{n>=0}, (ii) P(x) is the rational function g.f. of a(n)_{n>=1}, and (iii) C(x)+L(x)+B(x) is the partial fraction g.f. of a(n)_{n>=0}. (End)

V3-000686 | OEIS-A006172

a(n) = 1 + F(2*n+1) + (-1)^n*L(n).

The g.f. -(-2 -3*x + 19*x^2 - 17*x^3 + 4*x^4)/((x-1)*(x^2 - x - 1)*(x^2 - 3*x + 1)) conjectured by _Simon Plouffe_ in his 1992 dissertation is probably wrong. [The correct g.f. is (4 - 10*x - x^2 + 9*x^3 - 3*x^4)/((x - 1)*(x^2 - x - 1)*(x^2 - 3*x + 1)). From _Bruno Berselli_, Mar 09 2015] (Comment VII) We can now comment on the g.f., P(x), given by _Simon Plouffe_ and mentioned at the beginning of this Comment section. Expanding P(x) as a series, we obtain 2 + 9x + 10x^2 + 42x^3 + ..., the g.f. of {H_k}_{k>=1}. In fact, it is easily checked that P(x) = 1/x (H(x)-4). This settles the Plouffe conjecture as follows: (i) H(x) is the rational function g.f. of {H_k}_{k>=0}, (ii) P(x) is the rational function g.f. of {H_k}_{k>=1}, and (iii) C(x)+L(-x)+B2(x) is the partial fraction g.f. of {H_k}_{k>=0}. (End)

V3-000694 | OEIS-A006340

An "eta-sequence": [(n+1)*tau + 1/2] - [n*tau + 1/2], tau = (1 + sqrt(5))/2.

Conjecture: A006340 = continued fraction expansion of (2.729967741... = sup{f(n,1)}), where f(1,x) = x + 1 and thereafter f(n,x) = x + 1 if n is in the lower Wythoff sequence (A000201), else f(n,x) = 1/x. The first 12 values of f(n,1) are given in Example at A245216. - _Clark Kimberling_, Jul 14 2014

V3-000715 | OEIS-A006702

Solution to a Pellian equation: least x such that x^2 - n*y^2 = +- 1.

Apparently the generating function of the sequence of the denominators of continued fraction convergents to sqrt(n) is always rational and of form p(x)/[1 - C*x^m + (-1)^m * x^(2m)], or equivalently, the denominators satisfy the linear recurrence b(n+2m) = C*b(n+m) - (-1)^m * b(n). If so, then it seems that a(n) is half the value of C for each nonsquare n, or 1. See A003285 for the conjecture regarding m. The same conjectures apply to the sequences of the numerators of continued fraction convergents to sqrt(n). - _Ralf Stephan_, Dec 12 2013 The conjecture is true, cf. link. - _Jan Ritsema van Eck_, Mar 08 2021

V3-000729 | OEIS-A007061

The Ehrenfeucht-Mycielski sequence (1,2-version): a maximally unpredictable sequence.

Sutner continues: All words of length k seem to appear in the first 2^{k+2} bits. This is true for the first billion bits of the sequence, but no proof is known. The main open problem is whether the limiting density of 0's is 1/2. It seems to require a large amount of effort just to show that it is bounded away from 0, never mind some of the more exotic properties of the sequence (see the Sutner reference).

a(1)=2, a(2)=5; for n >= 3, a(n) is smallest number which is uniquely of the form a(j) + a(k) with 1 <= j < k < n.

Comments from _Joshua Zucker_, May 24 2006: "Concerning the conjecture about periodicity mod 126. Out of the first 300 terms, only the 2 and 12 are even. But if you neglect those first 6 terms, mod 2 they're all odd, mod 9 it goes: 0 4 6 1 7 4 6 8 7 2 4 6 8 5 0 8 1 2 5 7 0 2 4 6 1 5 0 2 8 1 5 7 which appears to repeat indefinitely and mod 7 it goes: 0 2 6 1 3 0 2 6 5 4 6 1 2 6 1 3 5 4 1 2 4 0 5 0 2 4 6 1 5 2 6 1 which also appears to repeat indefinitely. "The Mathworld link cites a proof that sequences of this type (2,n) have only two even terms and another proof that sequences with only finitely many even terms must eventually have periodic first differences. So I think the period 32 difference of 126 conjecture may be proved in those references."

V3-000741 | OEIS-A007310

Numbers congruent to 1 or 5 mod 6.

Numbers n such that (Sum_{k = 1..n} k^14) mod n = 0. (Conjectured) - _Gary Detlefs_, Dec 27 2011 The above conjecture is true. Apply Ireland and Rosen, Proposition 15.2.2. with m = 14 to obtain the congruence 6*(Sum_{k = 1..n} k^14)/n = 7 (mod n), true for all n >= 1. Suppose n is coprime to 6, then 6 is a unit in Z/nZ, and it follows from the congruence that (Sum_{k = 1..n} k^14)/n is an integer. On the other hand, if either 2 divides n or 3 divides n then the congruence shows that (Sum_{k = 1..n} k^14)/n cannot be integral. (End)

V3-000742 | OEIS-A007323

Number of numerical semigroups of genus n; conjecturally also the number of power sum bases for symmetric functions in n variables.

Number of numerical semigroups of genus n; conjecturally also the number of power sum bases for symmetric functions in n variables. The theorem alluded to in the email by Zagier is due to Kakeya, not Kakutani (see references.) The theorem states that if a sequence of n positive integers k1, k2,..., kn forms the complement of a numerical semigroup, then the power sums p_k1, p_k2,..., p_kn forms a

basis for the rational function field of symmetric functions in n variables. Kakeya conjectures that every power sum basis of the symmetric functions has this property, but this is still an open problem. Thanks to user Gjergji Zaimi on Math Overflow for the references. - _Trevor Hyde_, Oct 18 2018 Conjectures: A) a(n) >= a(n-1)+a(n-2); B) a(n)/(a(n-1)+a(n-2)) approaches 1; C) a(n)/a(n-1) approaches the golden ratio; D) a(n) >= a(n-1). Conjectures A, B, C, D were presented by M. Bras-Amorós in the seminar Algebraic Geometry, Coding and Computing, in Segovia, Spain, in 2007, and at IMNS 2018 in Granada, Spain, in 2008. Conjectures A, B, C were then published in the Semigroup Forum, 76 (2008), 379-384. Conjectures B and C are proved in the paper by Zhai, 2011. - _Maria Bras-Amorós_, Oct 24 2007, corrected Aug 31 2009

V3-000770 | OEIS-A007691

Multiply-perfect numbers: n divides sigma(n).

Luca's solution of problem 11090, which proves that for k>1 there are an infinite number of n such that n divides sigma_k(n), does not apply to this sequence. However, it is conjectured that this sequence is also infinite. - _T. D. Noe_, Nov 04 2007 Conjecture: If n is such that 2^n-1 is in A066175 then a(n) is a triangular number. - _Ivan N. Ianakiev_, Aug 26 2013 Conjecture: Every multiply-perfect number is practical (A005153). I've verified this conjecture for the first 5261 terms with abundancy > 2 using Achim Flammenkamp's data. The even perfect numbers are easily shown to be practical, but every practical number > 1 is even, so a weak form says every even multiply-perfect number is practical. - _Jaycob Coleman_, Oct 15 2013 The only terms m > 1 of this sequence that are not in A145551 are m for which sigma(m)/m is not a divisor of m. Conjecture: after 1, A323653 lists all such m (and no other numbers). - _Antti Karttunen_, Mar 19 2021

V3-000795 | OEIS-A008319

Smallest number that is sum of squares of distinct earlier terms.

Resta's conjecture is correct. Let x = floor(sqrt(n) - 12). For n > 1935, x^2 > n/2. For n > 1853, n - x^2 > 892. So n > 1935 can be decomposed into x^2 plus a number greater than 892. Since the other number is smaller than x^2, any decomposition into squares will use only numbers smaller than x. By induction, all numbers greater than 1935 (and hence greater than 892) are in this sequence. - _Charles R Greathouse IV_, Oct 06 2011

猜想/问题提及段 | historical_or_current_mention_unreviewed | R. Muller | 2026-10-24

V3-000797 | OEIS-A008364

11-rough numbers: not divisible by 2, 3, 5 or 7.

Conjecture: these are numbers n such that (Sum_{k=1..n} k^4) mod n = 0 and (Sum_{k=1..n} k^6) mod n = 0. - _Gary Detlefs_, Dec 20 2011 The above conjecture is true. Let m be even and let the m-th Bernoulli number be written in reduced form as Bernoulli(m) = N(m)/D(m). Apply Ireland and Rosen, Proposition 15.2.2, to show the congruence

D(m)*(Sum_{k = 1..n} k^m)/n = N(m) (mod n) holds for all n >= 1. It follows easily from this congruence that (Sum_{k = 1..n} k^m)/n is integral iff n is coprime to D(m). Now Bernoulli(4) = -1/(2*3*5) and Bernoulli(6) = 1/(2*3*7) so the numbers n such that both (Sum_{k=1..n} k^4) mod n = 0 and (Sum_{k=1..n} k^6) mod n = 0 are exactly those numbers coprime to the primes 2, 3, 5 and 7, that is, the 11-rough numbers. (End) Conjecture: these are numbers n such that (n^6 mod 210 = 1) or (n^6 mod 210 = 169). - _Gary Detlefs_, Dec 30 2011 The second Detlefs conjecture above is true and extremely easy to verify with some basic properties of congruences: take the terms of this sequence up to 209 and compute their sixth powers modulo 210: there should only be 1's and 169's there. Then take the complement of this sequence up to 210, where you will see no instances of 1 or 169. - _Alonso del Arte_, Jan 12 2014 It is well-known that the product of 7 consecutive integers is divisible by 7!. Conjecture: This sequence is exactly the set of positive values of r such that (Product_{k = 0..6} n + k*r)/7! is an integer for all n. - _Peter Bala_, Nov 14 2015 This conjecture is true. The first part of the proof deals with numbers not in A008364, i.e., numbers which are divisible by p (p either 2, 3, 5, 7). Let r = p*s and n = 1, then (Product_{k = 0..6} n + k*r) is not divisible by p, because none of the factors 1 + k*p*s are divisible by p. Hence dividing the product by 7! does not return an integer.

V3-000798 | OEIS-A008365

13-rough numbers: positive integers that have no prime factors less than 13.

Conjecture: Numbers n such that n^24 is congruent to {1,421,631,841} mod 2310. - _Gary Detlefs_, Dec 30 2011 Gary Detlefs' conjecture of Dec 30 2011 is false: the list of residues is incomplete. The smallest counterexample is n = 17 = a(3). Indeed, 17^24 == 1 (mod 210), while 17 == 6 (mod 11) and 6^4 == 9 (mod 11), so the Chinese remainder theorem gives 17^24 == 1681 (mod 2310). The correct statement is: n is a term of A008365 iff n^24 == 1, 421, 631, 841, or 1681 (mod 2310). Proof: Suppose gcd(n,2310) = 1. Since 1, 2, 4, and 6 all divide 24, Fermat's little theorem gives n^24 == 1 (mod p) for p = 2, 3, 5, and 7, hence n^24 == 1 (mod 210). Modulo 11, Fermat's little theorem gives n^24 == n^4. The map x -> x^4 on (Z/11Z)^* has kernel of size gcd(4,10) = 2, hence image of size 5; this image is precisely the set of nonzero quadratic residues {1,3,4,5,9}. Since 210 == 1 (mod 11), every residue congruent to 1 modulo 210 has the form 1 + 210*j, with 1 + 210*j == 1 + j (mod 11). Thus the five possible values modulo 11 correspond to j = 0, 2, 3, 4, 8, giving exactly the residues 1, 421, 631, 841, and 1681 modulo 2310. Conversely, each of these five residues is coprime to 2310, so if n^24 is congruent to one of them modulo 2310, then gcd(n^24,2310) = 1, and therefore gcd(n,2310) = 1. - _Eiver Rodríguez_, Sep 15 2026

V3-000803 | OEIS-A008486

Expansion of (1 + x + x^2)/(1 - x)^2.

Conjecture: This is also the maximum number of edges possible in a planar simple graph with n+2 vertices. - _Dmitry Kamenetsky_, Jun 29 2008 The conjecture is correct. Proof: For n=0 the theorem holds, the maximum planar graph has n+2=2 vertices and 1 edge. Now suppose that we have a connected planar graph with at least 3 vertices. If it contains a face that is not a triangle, we can add an edge that divides this face into two without breaking its planarity. Hence all maximum planar graphs are triangulations. Euler's formula for planar graphs states that in any planar simple graph with V vertices, E edges and F faces we have V+F-E=2. If all faces are triangles, then F=2E/3, which gives us E=3V-6. Hence for n>0 each maximum planar simple graph with n+2 vertices has 3n edges. - _Michal Forisek_, Apr 23 2009 a(n) is conjectured to be the number of polygons added after n iterations of the polygon expansions (type A, B, C, D & E) shown in the Ngaokrajang link. The patterns are supposed to become the planar Archimedean net 3.3.3.3.3.3, 3.6.3.6, 3.12.12, 3.3.3.3.6 and 4.6.12 respectively when n - > infinity. - _Kival Ngaokrajang_, Dec 28 2014 Conjecture: let m = n + 2, p is the polyhedron formed by the convex hull of m points, q is the number of quadrilateral faces of p (see the Wikipedia link below), and f(m) = a(n) - q. Then f(m) would be the solution of the Thompson problem for all m in 3-space. - _Sergey Pavlov_, Feb 03 2017

V3-000804 | OEIS-A008544

Triple factorial numbers: Product_{k=0..n-1} (3*k+2).

The Mathar conjecture is true. Generally from the factorial form, the last term is the "extra" product beyond the prior term, from k=n-1 and 3k+2 evaluates to 3*(n-1)+2 = 3n-1, yielding a(n) = a(n-1)*(3n-1) (eqn1). Similarly, a(n) = a(n-2)*(3n-1)*(3(n-2)+2) = a(n-2)*(3n-1)*(3n-4) (eqn2) and a(n) = a(n-3)*(3n-1)*(3n-4)*(3*(n-2)+2) = a(n-3)*(3n-1)*(3n-4)*(3n-7) (eqn3). We equate (eqn2) and (eqn3) to get a(n-2)*(3n-1)*(3n-4) = a(n-3)*(3n-1)*(3n-4)*(3n-7) or a(n-2)+(7-3n)*a(n-3) = 0 (eqn4). From (eqn1) we have a(n)+(1-3n)*a(n-1) = 0 (eqn5). Combining (eqn4) and (eqn5) yields a(n)+(1-3n)*a(n-1)+a(n-2)+(7-3n)*a(n-3) = 0. - _Bill McEachen_, Jan 01 2016

V3-000833 | OEIS-A010052

Characteristic function of squares: a(n) = 1 if n is a square, otherwise 0.

a(n*m) = a(n/gcd(n,m))*a(m/gcd(n,m)) for all n and m > 0 (conjectured). - _Velin Yanev_, Feb 13 2019 [Proof from _Michael B. Porter_, Feb 16 2019: If nm is a square, nm = product_i (p_i^2), where p_i are prime, not necessarily distinct. Each p_i either appears twice in n, twice in m, or one time in each and therefore in the gcd. So n/gcd(n,m) and m/gcd(n,m) are both squares. If nm is not a square, there is a q_j that appears in one of n or m but not in the gcd. So either n/gcd(n,m) or m/gcd(n,m) is not a square.]

V3-000835 | OEIS-A010059

Another version of the Thue-Morse sequence: let A_k denote the first 2^k terms; then A_0 = 1 and for k >= 0, A_{k+1} = A_k B_k, where B_k is obtained from A_k by interchanging 0's and 1's.

Two conjectures: If n is even, the ratio of 1's to 0's = 1:1. Conjecture (verified for the first 280000 entries): this is the characteristic function of A001969. - _R. J. Mathar_, Sep 05 2008 Proof of these three conjectures: the first two follow directly from the third, because the sequence A010059 is the binary complement of the Thue-Morse sequence A010060. For the third conjecture: the odious and evil numbers occur as quadruples EOOE and OEEO, simply by their definition. To obtain the mod 2 version of the interleave of the odious and evil numbers we therefore have to apply a transformation

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-000840 | OEIS-A010767

Decimal expansion of 4th root of 2.

Conjecture: Equals Sum_{k>=0} A007096(k) / exp(k*Pi). - _Simon Plouffe_, Sep 09 2025 Plouffe's conjecture is correct: Sum_{k >= 0} A007096(k) / exp(k*Pi) = eta(q^2)^6 / (eta(q)^4 * eta(q^4)^2) evaluated at q = exp(-Pi), with the convention for Dedekind's eta function that if q = exp(2*Pi*i*t) then eta(q) = eta(t). At q = exp(-Pi), t = i/2. Hence the sum equals eta(i)^6/(eta(i/2)^4 * eta(2*i)^2), which simplifies to 2^(1/4) using the known values eta(i) = alpha/2, eta(i/2) = alpha/2^(7/8) and eta(2*i) = alpha/2^(11/8), where alpha = Gamma(1/4)/Pi^(3/4).

V3-000842 | OEIS-A010791

a(n) = n!*(n+2)!/2.

This sequence has been shown to contain infinitely many squares. From the Hong and Liu abstract: Recently Cilleruelo proved that the product Product_{k=1..n} (k^2 + 1) is a square only for n = 3 which confirms a conjecture of Amdeberhan, Medina and Moll. In this paper, we show that the sequence Product_{k=2..n} (k^2 - 1) contains infinitely many squares. Furthermore, we determine all squares in this sequence. We also give a formula for the p-adic valuation of the terms in this sequence. - _Jonathan Vos Post_, Oct 21 2008

V3-000843 | OEIS-A010815

From Euler's Pentagonal Theorem: coefficient of q^n in Product_{m>=1} (1 - q^m).

Conjecture: Sum_{k>=0} a(k) / exp(k*Pi) = (1/2) * exp(1/24*Pi) * Pi^(1/4) * 2^(5/8) / Gamma(3/4) = A259148. - _Simon Plouffe_, Sep 09 2025 The conjecture is correct: By Euler's Pentagonal Number Theorem, the sum equals Product_{k >= 1} (1 - exp(-Pi*k)) = eta(i/2)*exp(Pi/24), where eta(t) = q^(1/24) * Product_{n >= 1} (1 - q^n), q = exp(2*Pi*i*t), is Dedekind's eta fumction. The conjecture follows from the standard result that eta(i/2) = Gamma(1/4)/(2^(7/8)*Pi^(3/4)) (see, for example, the Wikipedia entry on the eta function) and the reflection formula for the Gamma function. - _Peter Bala_, May 22 2026

V3-000886 | OEIS-A014442

Largest prime factor of n^2 + 1.

All a(n) except for a(1) = 2 are the Pythagorean primes, i.e., primes of form 4*k + 1. Conjecture: every Pythagorean prime appears in a(n) at least once. Conjecture: every Pythagorean prime p appears exactly two times among the first p integers of the sequence. Further: if a(i) = a(j) = p and both i and j are less than p (and i is not equal to j), then i + j = p and ij == 1 (mod p). [If a(k) = p as well, then k > p; in fact, k is in A256011.] Two examples: a(2) = a(3) = 5, with 2 + 3 = 5 and 2*3 = 6 == 1 (mod 5); a(4) = a(13) = 17, with 4 + 13 = 17 and 4*13 = 52 == 1 (mod 17). (End) The conjecture is true. If p is a Pythagorean prime, -1 is a quadratic residue mod p. Then -1 has exactly two square roots mod p, i.e., there are exactly two integers x,y with 1 <= x,y <= p-1 such that x^2 == y^2 == -1 (mod p), i.e., p divides x^2 + 1 and y^2 + 1, and moreover y == -x (mod p) so x + y = p, and x*y == -x^2 == 1 (mod p). Any other prime factor q of x^2 + 1 must divide (x^2 + 1)/p, and since x^2+1 < p^2 we have q < p, so a(x) = p and similarly a(y) = p. - _Robert Israel_, Jun 11 2015 Conjecture: if n is even and a(n) > n, then n+a(n) is in A256011. Examples: 2 + a(2) = 2 + 5 = 7, 4 + a(4) = 4 + 17 = 21, 6+a(6) = 6+37 = 43, and so on. Note that 18+a(18) is NOT in A256011, but 18 itself is. - _Michael Kaltman_, Jun 13 2015

V3-000894 | OEIS-A014577

The regular paper-folding sequence (or dragon curve sequence). Alphabet {1,0}.

Since the Heighway dragon is composed of right angles, it can be mapped with unit trajectories (Right = 1, Left = (-1), Up = i and Down = -i) on the complex plane where i = sqrt(-1). The initial (0th) iterate is chosen in this case to be the unit line from (0,0) to (-1,0). Then follow the directions below as indicated, resulting in a reflected variant of the dragon curve shown at the Eric Weisstein link. The conjectured system of complex plane trajectories is: The conjecture succeeds through the 4th iterate. It appears that to generate the (n+1)-th row, bring down the n-th row as the left half of row (n+1). For the right half of row (n+1), bring down the n-th row but change the signs of the first half of row n. For example, to get the complex plane instructions for the third iterate of the dragon curve, bring down (-1, i, 1, i) as the left half, and the right half is (1, -i, 1, i). (End)

V3-000899 | OEIS-A014617

Antidiagonals of the prime-composite array B(m,n) (see A067681) that are zeros from the first Borve conjecture.

Antidiagonals of the prime-composite array B(m,n) (see A067681) that are zeros from the first Borve conjecture. Let c(m) be the m-th composite and p(n) be the n-th prime. The prime-composite array, B, is defined such that each element B(m,n) is the highest power of p(n) that is contained within c(m). The m-th antidiagonal of the array consists of the m elements B(m,1), B(m-1,2), B(m-2,3), ..., B(1,m). The First Borve Conjecture states that there are infinitely many zero-only antidiagonals.

V3-000902 | OEIS-A014742

Expansion of (1+x^2)/(1 - 2*x - 2*x^2 + x^3).

The preceding comment is a conjecture using a(n) = floor(LL(n)*L(n)) with LL(n) = sqrt(F(n+2)^2 + F(n)^2) and L(n) = LL(n-1), n >= 1 (its author agreed with this in an email). See also, e.g., the Koshy reference for the dissection fallacy, sect. 6, 100 - 108. The proof of the conjecture uses first the identity (LL(n)*LL(n-1))^2 - a(n)^2 = + 1 with a(n) = F(n-1)*F(n) + F(n+1)*F(n+2) (see the formula section for a(n)). This identity is due to the factorization of the left-hand side which is A(n)^2 with A(n) = F(n)*F(n+1) - F(n-1)*F(n+2). But A(n) = (-1)^(n+1) is a special instance of a well known Fibonacci identity (Koshy, p. 88, Nr. 19 for h=-1, k=2, F(-1) = 1). Now one has (LL(n)*LL(n-1))^2 = 1 + a(n)^2, that is LL(n)*LL(n-1) = sqrt(1 + a(n)^2). Because a(n) < sqrt(1 + a(n)^2) < a(n) + 1 (just square both inequalities using a(n) > 0) one has now proved that floor(LL(n)*LL(n-1)) = a(n), n >= 1. (End)

V3-000941 | OEIS-A019429

Continued fraction for tan(1/6).

Conjecture: a(n) = (-1+3*(-1)^n-6*(-1+(-1)^n)*n)/2 for n>1. a(n) = 2*a(n-2)-a(n-4) for n>5. G.f.: x*(x^4-x^3+6*x^2+x+5) / ((x-1)^2*(x+1)^2). - _Colin Barker_, May 28 2013 The above conjectures are correct. The simple continued fraction expansion for tan(1/6) may be derived by setting z = 1/6 in Lambert's continued fraction tan(z) = z/(1 - z^2/(3 - z^2/(5 - ...))) and then, after using an equivalence transformation, making repeated use of the identity 1/(n - 1/m) = 1/((n - 1) + 1/(1 + 1/(m - 1))).

V3-000949 | OEIS-A019505

a(1)=1; for n > 1, a(n) is the smallest number with the same number of divisors as 2*a(n-1).

Conjectures: Subsequence of A002182. [This conjecture is false. The 64th term is 97039187544499200, which has exactly 63360 divisors, but is NOT in A002182; which has the smaller number 74801040398884800, which has 64512 divisors. - _J. Lowell_, Nov 29 2021] The value of c is less than twice b. [This conjecture is false. Terms 121-123 are 93635537220943523586899838720000, 14258138622280036546187020896000, and 26139920807513400334676204976000. - _J. Lowell_, Jan 28 2022] The primes and the powers of 3 are the only numbers that never "come and go" from the lists of divisors of the numbers in the sequence as the terms advance. [This conjecture is false. The 122nd term, 14258138622280036546187020896000, is a multiple of 3^5=243, but the 123rd term, 26139920807513400334676204976000, is not. - _J. Lowell_, Jan 28 2022]

V3-000950 | OEIS-A019565

The squarefree numbers ordered lexicographically by their prime factorization (with factors written in decreasing order). a(n) = Product_{k in I} prime(k+1), where I is the set of indices of nonzero binary digits in n = Sum_{k in I} 2^k.

Conjecture: there are no finite cycles of any length. My grounds for this conjecture: any finite cycle in this sequence, if such cycles exist at all, must have at least one member that occurs somewhere in A285319, the terms that seem already to be quite rare. Moreover, any such a number n should satisfy in addition to A019565(n) < n also that A048675^{k}(n) is squarefree, not just for k=0, 1 but for all k >= 0. As there is on average a probability of only 6/(Pi^2) = 0.6079... that any further term encountered on the trajectory of A048675 is squarefree, the total chance that all of them would be squarefree (which is required from the elements of A019565-cycles) is soon minuscule, especially as A048675 is not very tightly bounded (many trajectories seem to skyrocket, at least initially). I am also assuming that usually there is no significant correlation between the binary expansions of n and A048675(n) (apart from their least significant bits), or, for that matter, between their prime factorizations. See also the slightly stronger conjecture in A285320, which implies that there would neither be any two-way infinite cycles. If either of the conjectures is false (there are cycles), then certainly neither sequence A285332 nor its inverse A285331 can be a permutation of natural numbers. (End) The conjecture made in A087207 (see also A288569) implies the two conjectures mentioned above. A further constraint for cycles is that in any A019565-trajectory which starts from a squarefree number (A005117), every other term is of the form 4k+2, while every other term is of the form 6k+3. - _Antti Karttunen_, Jun 18 2017

V3-000975 | OEIS-A020882

Ordered hypotenuses (with multiplicity) of primitive Pythagorean triangles.

The density of such points in a circle with radius squared = a(n) is ~ Pi * a(n). Restricting to a > b > 0 reduces this by a factor of 1/8; requiring gcd(a,b)=1 provides a factor of 6/Pi^2; and a, b not both odd is a factor of 2/3. (2/3, not 3/4, because the case a, b both even has already been eliminated.) Multiplying, a(n) * Pi * 1/8 * 6/Pi^2 * 2/3 is a(n) / (2 * Pi). But n is approximately this number of points, so a(n) ~ 2 * Pi * n. Conjectured by _David W. Wilson_, proof by _Franklin T. Adams-Watters_, Mar 15 2015

V3-000976 | OEIS-A020903

Lim f(f(...f(n))) where f is the fractal sequence given by f(n)=A002260(n+1).

Conjecture: a(n) and a(n+1) are never both 2. - _Robert Israel_, Sep 03 2015 Proof of the conjecture: Let f(n)=A002260(n+1)=1,2,1,2,3,1,2,3,4,... Then (f(n)) is a concatenation of ladders 1,2 followed by 1,2,3 followed by 1,2,3,4 etc. The proof is by induction. Note that the sequence (a(n)) can be seen as map from the positive integers to the positive integers. The induction starts from the observation that a(1) and a(2) are not both 2. We use that f(k)<k for all k>2. Any pair (k,k+1) from a ladder has image (a(k),a(k+1)) = (a(f(k)),a(f(k+1))), which occurs either as image of two adjacent integers (j,j+1) earlier in the sequence, and so will not be equal to (2,2) by the induction hypothesis, or as image of a pair (j,1), whose image is also not equal to (2,2). The same holds for a pair consisting of the end of a ladder and the next entry. (End)

V3-001000 | OEIS-A022544

Numbers that are not the sum of 2 squares.

Conjecture: if k is not the sum of 2 squares then sigma(k) == 0 (mod 4) (the converse does not hold, as demonstrated by the entries in A025303). - _Benoit Cloitre_, May 19 2002 Proof of Cloitre's 2002 conjecture: if n is not the sum of 2 squares, then sigma(n) == 0 (mod 4). By the sum-of-two-squares theorem, n is not a sum of two squares iff some prime p == 3 (mod 4) divides n to an odd power e = 2j+1. For such p: sigma(p^e) = Sum_{k=0..e} p^k. Since p==3(mod 4), p^k==1(mod 4) for k even and p^k==3(mod 4) for k odd. As e is odd, e+1 is even, so the terms pair as (p^0+p^1)+(p^2+p^3)+...+(p^(e-1)+p^e), with each pair == 1+3 = 0 (mod 4). Hence sigma(p^e) == 0 (mod 4), and by multiplicativity of sigma, sigma(n) == 0 (mod 4). QED. - _Marc-André Leduc_, Mar 11 2026

V3-001051 | OEIS-A024813

Positive integers m for which f(m-1) < f(m) < f(m+1), where f(m) = floor(cot(Pi/(2m))).

Conjecture (verified for m < 10^6 by _M. F. Hasler_): a(n) = 2*A024812(n) - n + 1, n=1,2,.... - _L. Edson Jeffery_, Mar 21 2013 The above conjecture follows from the Laurent series for cot(x) = 1/x - x/3 + O(x^3) and the conjecture n/a(n) ~ 4/Pi-1. - _M. F. Hasler_, Mar 25 2013 Proof of both L. Edson Jeffery's conjecture above and M. F. Hasler's asymptotic conjecture below: Let g(x) = cot(Pi/(2*x)). For x >= 2, g'(x) = (2/Pi)*((Pi/(2*x))/sin(Pi/(2*x)))^2 is strictly decreasing with 2/Pi < g'(x) <= g'(2) = Pi/4. By the Mean Value Theorem, for all m >= 2, g(m+1) - g(m) <= Pi/4 < 1 and g(m+2) - g(m) > 4/Pi > 1. Hence f(m) = floor(g(m)) takes every positive integer value either once or twice. Since f(1) = 0, among the A024812(n) - 1 positive integers below A024812(n), exactly n - 1 are taken once and A024812(n) - n are taken twice, giving a(n) = 1 + (n - 1) + 2*(A024812(n) - n) + 1 = 2*A024812(n) - n + 1 for all n >= 1. Since A024812(n) = floor(cot(Pi/(2*a(n)))) = (2/Pi)*a(n) + O(1), substituting into a(n) = 2*A024812(n) - n + 1 immediately yields lim_{n->oo} n/a(n) = 4/Pi - 1. - _Hriday Rungta_, Oct 04 2026 n/a(n) ~ 4/Pi - 1 (as n -> oo), or a(n) ~ 3.65979 n. (Conjectured.) - _M. F. Hasler_, Mar 25 2013 Conjecture: a(n) = a(n-1) + a(n-3) - a(n-4); g.f.: x*(2*x^15-2*x^14-x^3+5*x^2+3*x+4) / ((x-1)^2*(x^2+x+1)). - _Colin Barker_, Jan 03 2014 Barker's 2014 recurrence conjecture is false: a(14)+a(12)-a(11) = 51+45-40 = 56, but a(15) = 54. - _Michal Buran_, Mar 24 2026

V3-001142 | OEIS-A026274

Greatest k such that s(k) = n, where s = A026272.

Conjecture: This sequence consists precisely of those numbers without a 1 or 2 in their Zeckendorf representation. [In other words, numbers which are the sum of distinct nonconsecutive Fibonacci numbers greater than 2.] - _Charles R Greathouse IV_, Jan 28 2015 Proof of the conjecture by _Charles R Greathouse IV_. Then the same characterization holds for n with d(1)d(0) = 01, since 11 does not appear in a Zeckendorf expansion. But such an n has predecessor n-1 which always has an expansion with d(1)d(0) = 00. Combined with my comment from March 2018, this proves the conjecture (ignoring n = 0). (End) a(n) = A003622(n+1) - 1 for n>1 (conjectured). - _Michel Marcus_, Oct 30 2020 This conjectured formula follows directly from the formula a(n) = floor((n+1)*r^2)-2 in my Mar 12 2018 comment above. - _Michel Dekking_, Oct 31 2020

V3-001154 | OEIS-A026465

Length of n-th run of identical symbols in the Thue-Morse sequence A010060 (or A001285).

Under tau^2 the runs of length 1 are mapped to the sequence 1,2,1 of run lengths, and the runs of length 2 are mapped to the sequence 1,2,2,2,1 of run lengths. This proves John Layman's conjecture number (1): it follows that (a(n)) is fixed point of the morphism alpha Since alpha(1) and alpha(2) are both palindromes, this also proves Alexander Povolotsky's conjecture.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-001155 | OEIS-A026477

a(1) = 1, a(2) = 2, a(3) = 3; and for n > 3, a(n) = smallest number > a(n-1) and not of the form a(i)*a(j)*a(k) for 1 <= i < j < k < n.

Once a term with a given prime signature S (i.e., multiset of prime exponents) appears, then all numbers with the same prime signature follow. So either all or no terms with the same prime signature appear (first conjectured by _Charles R Greathouse IV_).

V3-001208 | OEIS-A027649

a(n) = 2*(3^n) - 2^n.

Related to the number of even a's in a nontrivial cycle (should one exist) in the 3x+1 Problem, where a <= floor(log_2(2*(3^n) - 2^n)). The value n correlates to the number of odds in such a nontrivial cycle. See page 1288 of Crandall's paper. Also, this relation gives another proof that the number of odds divided by the number of evens in a nontrivial cycle is bounded by log 2 / log 3 (this observation does not resolve the finite cycles conjecture as the value could be arbitrarily close to this bound). However, the same argument gives that log 2 / log 3 is less than or equal to the number of odds divided by the number of evens in a divergent sequence (should one exist), as log 2 / log 3 is the limit value for a cycle of an arbitrarily large length, where the length is given by the value n. - _Jeffrey R. Goodwin_, Aug 04 2011

V3-001212 | OEIS-A027833

Distances between successive 2's in sequence A001223 of differences between consecutive primes.

Conjecture: a(n) < log(A014574(n))^2. - _Thomas Ordowski_, Jul 21 2012 Conjecture: All positive integers are represented in this sequence. This is verified up to 184, by searching up to prime indexes of ~128000000. The rate of filling-in the smallest remaining gap among the integers, and the growth in the maximum value found, both slow down considerably relative to a fixed quantity of twin prime incidences examined in each pass. The maximum value found was 237. - _Richard R. Forberg_, Jul 28 2016

V3-001257 | OEIS-A030797

Decimal expansion of the constant x such that x^x = e. Inverse of W(1), where W is Lambert's function.

Conjecture: Another series can be defined as follows. Let z = a + b*i <> 0 be complex, and let z = v^v. Then log(z) + v = v*(1 + log(v)), so f(z, v) = (log(z) + v)/(1 + log(v)) = v. Suppose lim_{n -> infinity} (log(z) + v(n))/(1 + Log(v(n))) = v, for some sequence {v(n)}. Then, since v(n) -> v(n+1), similarly f_(n+1)(z, v) = v(n+1) = (log(z) + v(n))/(1 + log(v(n))). If Im(z) <> 0, recall that log(z) is multi-valued, so one might take both log(z) and log(v(n)) modulo 2*Pi*i. If Im(z) = 0 (i.e., if z is real), then one should use the recurrence f_(n+1)(z, v) = v(n+1) = (log(z) + v(n))/(1 + abs(log(v(n)))). For example, when z = e, we have lim_{n -> infinity} (1 + v(n))/(1 + abs(log(v(n)))) = 1.763222..., for v(0) <> 1/e, with apparent quadratic convergence, and most rapidly when v(0) = 1. Pathologies occur when v(0) is in the vicinity of a fixed point of f(z, v); e.g., if z = 2^(1/4), then such a fixed point is c = 0.806693797003867301..., so f_(n)(z, v) -> c, for all n, with a(0) near c. The constant c was calculated to 250 digits by Joerg Arndt. - _L. Edson Jeffery_, Apr 12 2011

V3-001259 | OEIS-A031172

a(n) = prime(n+10) - prime(n).

In principle, moderate values should appear infinitely many times, by analogy with twin primes hypothesis. For example, a(n) = 44 for n = 9, 17, 206, 1604467, 12905293, 18008874, 26545460, 32655424, 57848470, 58313630, 59022635, 66275281, 81581956, 123780499, 160884754, 167797255, 179786560, 181569324, 239542290, ... - _Zak Seidov_, Sep 14 2014, edited by _M. F. Hasler_, Dec 03 2018 According to the k-tuple conjecture, any admissible k-tuple of primes occurs with calculable nonzero asymptotic density, i.e., in particular, infinitely many times. For k = 11, number of primes in the interval [prime(n), prime(n+10)], the smallest possible diameter of a k-tuple is A008407(11) = 36, and there are A083409(11) = 2 such constellations: {0, 4, 6, 10, 16, 18, 24, 28, 30, 34, 36}, first occurring at A213646(1) = 1418575498573, and {0, 2, 6, 8, 12, 18, 20, 26, 30, 32, 36}, first occurring at A213647(1) = 11. The combined list { prime(n) | a(n) = 36 } is A257129. - _M. F. Hasler_, Dec 03 2018

V3-001293 | OEIS-A033093

Number of 0's when n is written in base b for 2<=b<=n+1.

Conjecture: lim inf a(n) = infinity. The lim inf grows quite slowly: e.g. a(2047)=7. Weaker conjecture: 2, 3 and 7 are the only n for which a(n) = 1. Note that a(n)=1 implies n=2 or n=2^k-1; probabilistically, the chance that 2^k-1 has no zeros just in base 3 is C^k, where C = (2/3)^(log(2)/log(3)) ~ .774, so the number of exceptions should be finite. It appears that 2^15-1 is the last n with no zeros in either base 2 or 3 (and it does have zeros in base 5). - _Franklin T. Adams-Watters_, Nov 07 2005

V3-001297 | OEIS-A033282

Triangle read by rows: T(n, k) is the number of diagonal dissections of a convex n-gon into k+1 regions.

The preceding conjecture by Lang is true. It is implicit in Copeland's 2011 comments in A086810 on the relations among a gf and its compositional inverse for that entry and inversion through A133437 (a differently normalized version of A111785), whose integer partitions are the same as those for A134685. (An inversion pair in Copeland's 2008 formulas below can also be used to prove the conjecture.) In addition, it follows from the relation between the inversion formula of A111785/A133437 and the enumeration of distinct faces of associahedra. See the MathOverflow link concernimg Loday and the Aguiar and Ardila reference in A133437 for proofs of the relations between the partition polynomials for inversion and enumeration of the distinct faces of the A_n associahedra, or Stasheff polytopes. - _Tom Copeland_, Dec 21 2017

V3-001309 | OEIS-A033919

Odd k for which k+2^m is composite for all m < k.

In an archived website, Payam Samidoost gives these numbers and other results about the dual Sierpiński problem. It is conjectured that, for each of these k<78557, there is an m such that k+2^m is prime. Then a covering argument would show that 78557 is the least odd number such that 78557+2^m is composite for all m. The impediment in the "dual" problem is that it is currently very difficult to prove the primality of large numbers of the form k+2^m. It is much easier to prove the Proth primes of the form k*2^m+1 which occur in the usual Sierpiński problem. According to the distributed search project "Five or Bust", 40291 is the only value of k < 78557 for which there is currently no m known making k + 2^m a prime or probable prime. - _T. D. Noe_, Jun 14 2007 and Phil Moore (moorep(AT)lanecc.edu), Dec 14 2009

V3-001313 | OEIS-A034007

First differences of A045891.

Conjecture 1: For compositions of n+k-1, a(n) is the number of runs of 1 of length k. Example: Among the compositions of 4+2-1 = 5, there are a(4) = 4 runs of two 1's: 3,[1,1]; [1,1],3; 1,2,[1,1] and [1,1],2,1. - _Gregory L. Simay_, Feb 18 2018 Conjecture 2: More generally, let R(n,m,k) = the number of runs of k m's in all compositions of n. Then R(n,m,k) = A045623(n-m*k) - 2*A045623(n-m*(k+1)) + A045623(n-m*(k+2)). For example, R(7,1,1) = A045623(6) - 2*A045623(5) + A045623(4) = 144 - 2*64 + 28 = 44 = a(7). - _Gregory L. Simay_, Feb 20 2018

V3-001321 | OEIS-A034383

Number of labeled groups.

Also by definition, a(n) >= A000001(n)*n!/A059773(n). If the conjecture A059773(2^r) = A002884(r) is true, then A059773(2^r) <= 2^(r^2), while A000001(2^r) >= 2^((2/27)*r^2*(r-6)) (see the Math Stack Exchange link below), so a(2^r)/A034381(2^r) tends to infinity quickly as r tends to infinity. The sequence is strictly increasing for the first 256 terms (a(256) > A034381(256) > A034381(255) = a(255) since 255 is in A003277). On the other hand, assuming that A059773(2^r) = A002884(r), then a(2^20)/(2^20)! >= A000001(2^20)/A002884(20) > 99798.4, while a(2^20+1)/(2^20)! = A034381(2^20+1)/(2^20)! = (2^20+1)/phi(2^20+1) since 2^20+1 = 17*61681 is in A003277, so we would have a(2^20) > a(2^20+1). It is conjectured a(2^r) > a(2^r+1) for all sufficiently large r. (End)

V3-001322 | OEIS-A034444

a(n) is the number of unitary divisors of n (d such that d divides n, gcd(d, n/d) = 1).

Conjecture: For any nonnegative integer k and positive integer n, the sum of the k-th powers of the unitary divisors of n is divisible by the sum of the k-th powers of the odd unitary divisors of n (note that this sequence lists the sum of the 0th powers of the unitary divisors of n). - _Ivan N. Ianakiev_, Feb 18 2018 The above conjecture is true. If n is odd, the asserted divisibility is equality. Otherwise, let n = m*(2^b), where b > 0 and m is odd. The set of unitary divisors of n is equal to the disjoint union of U(m) and {d*(2^b): d in U(m)}, where U(m) denotes the set of unitary divisors of m (all of which are odd). Hence the sum of the k-th powers of the unitary divisors of n = Sum_{d in U(m)} d^k + Sum_{d in U(m)} (d*2^b)^k = (1 + 2^(b*k)) * Sum_{d in U(m)} d^k = (1 + 2^(b*k)) * the sum of the k-th powers of the odd unitary divisors of n. - _Peter Bala_, May 20 2026 [Corrected by _David Radcliffe_, Jul 20 2026] Conjecture: Let b(i; n), n > 0, be multiplicative sequences for some fixed integer i >= 0 with b(i; p^e) = (Sum_{k=1..i+1} A164652(i, k) * e^(k-1)) * (i+2) / (i!) for prime p and e > 0. Then we have Dirichlet generating functions: Sum_{n > 0} b(i; n) / n^s = (zeta(s))^(i+2) / zeta((i+2) * s). Examples for i=0 this sequence, for i=1 A226602, and for i=2 A286779. - _Werner Schulte_, Feb 17 2022

V3-001325 | OEIS-A034693

Smallest k such that k*n+1 is prime.

Conjecture: for every n > 1 there exists a number k < n such that n*k + 1 is a prime. - _Amarnath Murthy_, Apr 17 2001 A stronger conjecture: for every n there exists a number k < 1 + n^(.75) such that n*k + 1 is a prime. I have verified this up to n = 10^6. Also, the expression 1 + n^(.74) does not work as an upper bound (counterexample: n = 19). - _Joseph L. Pe_, Jul 16 2002 Stronger version of the conjecture verified up to 10^9. - _Mauro Fiorentini_, Jul 23 2023 Conjecture: a(n) = O(log(n)*log(log(n))). - _Thomas Ordowski_, Oct 17 2014 I conjecture the opposite: a(n) / (log n log log n) is unbounded. See A194945 for records in this sequence. - _Charles R Greathouse IV_, Mar 21 2016

V3-001364 | OEIS-A036840

a(n) is the average of the repeating terms of {T(n,k)} rounded to the nearest integer (rounding up if there's a choice), if {T(n,k)} is eventually periodic; = 0 otherwise. Here T(n,k) is the "phi/sigma tug-of-war sequence with seed n" defined by T(n,1) = phi(n), T(n,2) = sigma(phi(n)), T(n,3) = phi(sigma(phi(n))), ..., T(n,k) = phi(T(n,k-1)) if k is odd and = sigma(T(n,k-1)) if k is even.

Conjecture: a(n) is never 0; i.e. the sequence {T(n,k)} is eventually periodic for every n.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Joseph L. Pe_, Jan 09 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-001365 | OEIS-A036845

a(n) = min_{k} {T(n,k)} where T(n,k) is the "phi/sigma tug-of-war sequence with seed n" defined by T(n,1) = phi(n), T(n,2) = sigma(phi(n)), T(n,3) = phi(sigma(phi(n))), ..., T(n,k) = phi(T(n,k-1)) if k is odd and = sigma(T(n,k-1)) if k is even.

Conjecture: The sequence {T(n,k)} is eventually periodic for every n, so a(n) can be computed in finite time. Conjecture: a(n) -> infinity as n -> infinity.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-001371 | OEIS-A037053

Smallest prime containing exactly n 0's.

Certain entries require n+3 digits such as a(13). Those which do not require three digits besides n zeros are in A085824. Conjecture: a prime of this form, A037053, requires at most three judiciously placed nonzero digits, two on the exterior and one inside. - _Robert G. Wilson v_ Conjecture 1: (following _Robert G. Wilson v_'s conjecture above and insight provided by Hans Havermann): terms with two substrings of zeros have first digit of 1. Conjecture 2: as n increases, there are more terms with two substrings of zeros than one consecutive string.

V3-001397 | OEIS-A038460

Maximal value of difference between successive primes among numbers < 10^n.

For 3 < n < 19, a(n) <= 6 (n - 1)(n - 2). Conjecture: for any n > 3, a(n) <= 6 (n - 1)(n - 2). Let q = 6 (n - 1)(n - 2) and d = (10^n) - (10^(n/2) - 1)^2. Since for any even n, d is the smallest difference between two consecutive squares of the form a^2 - b^2, where a^2 = 10^n, b = a - 1, for any even n > 2, d > 5q (where 3q is, according to the conjecture, not less than the sum of the three largest gaps between 4 consecutive primes p1...p4, or 3 * a(n), and 2q is, respectively, not less than the sum of the two largest gaps (p1 - p0) + (p5 - p4), or 2 * a(n)). In the same way, we can state that for any odd n > 3, if a^2 is the smallest square such that a^2 has (n+1) digits, b = a - 1, and d = a^2 - b^2, then d > 5q. The correctness of the above conjecture would establish the well-known Brocard's and Legendre's conjectures (see the link below for both definitions), since they are proved for the first 10000 primes. - _Sergey Pavlov_, Jan 30 2017

V3-001404 | OEIS-A039004

Numbers whose base-4 representation has the same number of 1's and 2's.

Conjecture: a(C(2n,n)-1) = 4^n - 1. (A000984 is C(2n,n)). - _Gerald McGarvey_, Nov 18 2007 We prove the McGarvey conjecture (A) a(e(n,n)-1) = 4^n-1, with e(n,m) = A034870(n,m) = binomial(2n,m), the even rows of Pascal's triangle. By the comment from Hendel in A034870, we have the function s(n,k) = #{n-digit, base-4 numbers with n-k more 1-digits than 2-digits}. As shown in A034870, (B) #s(n,k)= e(n,k) with # indicating cardinality, that is, e(n,k) = binomial(2n,k) gives the number of n-digit, base-4 numbers with n-k more 1-digits than 2-digits. We now show that (B) implies (A). By definition, s(n,n) contains the e(n,n) = binomial(2n,n) numbers with an equal number of 1-digits and 2-digits. The biggest n-digit, base-4 number is 333...3 (n copies of 3). Since 333...33 has zero 1-digits and zero 2-digits it follows that 333...333 is a member of s(n,n) and hence it is the biggest member of s(n,n). But 333...333 (n copies of 3) in base 4 has value 4^n-1. Since A039004 starts with index 0 (that is, 0 is the 0th member of A039004), it immediately follows that 4^n-1 is the (e(n,n)-1)st member of A039004, proving the McGarvey conjecture. (End) Conjecture: there is a constant c around 5 such that a(n) is asymptotic to c*n. - _Benoit Cloitre_, Nov 24 2002 That conjecture is false. The number of members of the sequence from 0 to 4^d-1 is binomial(2d,d) which by Stirling's formula is asymptotic to 4^d/sqrt(Pi*d). If Cloitre's conjecture were true we would have 4^d-1 asymptotic to c*4^d/sqrt(Pi*d), a contradiction. - _Robert Israel_, Jun 24 2015

V3-001428 | OEIS-A042963

Numbers congruent to 1 or 2 mod 4.

Equivalent to the following variation on Fermat's Diophantine m-tuple: 1 + the product of any two distinct terms is not a square; this sequence, which we'll call sequence S, is produced by the following algorithm. At the start, S is initially empty. At stage n, starting at n = 1, the algorithm checks whether there exists a number m already in the sequence, such that mn+1 is a perfect square. If such a number m is found, then n is not added to the sequence; otherwise, n is added. Then n is incremented to n + 1, and we repeat the procedure. Proof by Clark R. Lyons: We prove by strong induction that n is in the sequence S if and only if n == 1 (mod 4) or n == 2 (mod 4). Suppose now that this holds for all k < n. In case 1, either n == 1 (mod 4) or n == 2 (mod 4), and we wish to show that n does indeed enter the sequence S. That is, we wish to show that there does not exist m < n, already in the sequence at this point such that mn+1 is a square. By the inductive hypothesis m == 1 (mod 4) or m == 2 (mod 4). This means that both m and n are one of 1, 2, 5, or 6 mod 8. Using a multiplication table mod 8, we see that this implies mn+1 is congruent to one of 2, 3, 5, 6, or 7 mod 8. But we also see that mod 8, a perfect square is congruent to 0, 1, or 4. Thus mn+1 is not a perfect square, so n is added to the sequence. In case 2, n == 0 (mod 4) or n == 3 (mod 4), and we wish to show that n is not added to the sequence. That is, we wish to show that there exists m < n already in the sequence such that mn+1 is a perfect square. For this we let m = n - 2, which is positive since n >= 3. By the inductive hypothesis, since m == 1 (mod 4) or m == 2 (mod 4) and m < n, m is already in the sequence. And we have m*n + 1 = (n - 2)*n + 1 = n^2 - 2*n + 1 = (n - 1)^2, so mn+1 is indeed a perfect square, and so n is not added to the sequence. Thus n is added to the sequence if and only if n == 1 (mod 4) or n == 2 (mod 4). This completes the proof. - _Robert C. Lyons_, Jun 30 2016

V3-001478 | OEIS-A047222

Numbers that are congruent to {0, 2, 3} mod 5.

Conjecture: Apart from 0, the sequence gives the values for c/6, such that an infinite number of primes, p, result in both p^2-c and p^2+c being positive primes, except when c is a square. When c is square solutions exist for c (both within and outside of the a(n) set), but occur at only a single prime p. See A274609. Other c values with only one prime providing a solution occur when p^2-c=3. See A274610. The only remaining c values with single p solutions are: c=2 (with p=3) and c=6 (with p=5). - _Richard R. Forberg_, Jun 26 2016

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-001481 | OEIS-A047363

Numbers that are congruent to {0, 2, 3, 4, 5} mod 7.

Conjecture: Apart from 0, and the further exclusions noted below, the sequence gives the values of c/6 such that an infinite number of primes, p, result in both p^3+c and p^3-c being positive primes. Taking the complement we say: the excluded c/6 values are {1,6} mod 7. See A005097 for a conjecture on the modulo patterns of excluded c/6 values for the general case of p^q + c and p^q - c both prime, for any q > 0, and see A047222 for q=2. Note that polynomial factorization also excludes a few c/6 values. This occurs here when c is an even cube (A016743), which requires a further exclusion of certain c/6 values in this sequence when (6c)^3/6 == 0 (mod 7), or c/6 = {0, 12348, 98784, ...}. - _Richard R. Forberg_, Jun 28 2016

V3-001505 | OEIS-A048247

Every prime occurs to this power in some factorial.

There are no primes in the sequence, as the prime p fails the base p test. The set of positive integers failing the base p test for membership has density 1/p. Also, when n is a nonmember of the set, any base p whose test n fails has p<=n. Therefore one conjectural estimate for the number of members of the set <=x would be x*product{primes p<=x}(1-1/p) ~ e^(-gamma)*x/log(x). However, a similar heuristic for the primes fails, as pi(x) ~ x/log(x) and not e^(-gamma)*x/log(x). Here gamma denotes the Euler-Mascheroni constant. - _David L. Harden_, Aug 24 2002

V3-001521 | OEIS-A048888

a(n) = Sum_{m=1..n} T(m,n+1-m), array T as in A048887.

Define a "numbral arithmetic" by replacing addition with binary bitwise inclusive-OR (so that [3] + [5] = [7] etc.) and multiplication becomes shift-&-OR instead of shift-&-add (so that [3] * [3] = [7] etc.). [d] divides [n] means there exists an [e] with [d] * [e] = [n]. For example the six divisors of [14] are [1], [2], [3], [6], [7] and [14]. Then it appears that this sequence gives the number of proper divisors of [2^n-1]. Conjecture confirmed by Richard C. Schroeppel, Dec 14 2001. (End)

V3-001529 | OEIS-A049310

Triangle of coefficients of Chebyshev's S(n,x) := U(n,x/2) polynomials (exponents in increasing order).

The number of zeros Z(n) of the S(n, x) polynomials in the open interval (-1,+1) is 2*b(n) for even n >= 0 and 1 + 2*b(n) for odd n >= 1, where b(n) = floor(n/2) - floor((n+1)/3). This b(n) is the number of integers k in the interval (n+1)/3 < k <= floor(n/2). See a comment on the zeros of S(n, x) above, and b(n) = A008615(n-2), n >= 0. The numbers Z(n) have been proposed (with a conjecture related to A008611) by _Michel Lagneau_, as the number of zeros of Fibonacci polynomials on the imaginary axis (-I,+I), with I=sqrt(-1). They are Z(n) = A008611(n-1), n >= 0, with A008611(-1) = 0. Also Z(n) = A194960(n-4), n >= 0. Proof using the A008611 version. A194960 follows from this.

V3-001568 | OEIS-A051397

a(n) = (2*n-2)*(2*n-1)*a(n-1)+1.

Conjecture: a(n) +(-4*n^2+6*n-3)*a(n-1) +2*(2*n-3)*(n-2)*a(n-2)=0. - _R. J. Mathar_, Jan 31 2014 Mathar's conjectured recurrence a(n) = (4*n^2 - 6*n + 3)*a(n-1) - (2*n - 3)*(2*n - 4)*a(n-2) follows easily from the defining recurrence. The sequence b(n) := (2*n - 1)! also satisfies Mathar's recurrence but with b(1) = 1, b(2) = 6. This leads to the continued fraction representation a(n) = (2*n - 1)!*(1 + 1/(6 - 6/(21 - 20/(43 - ... - (2*n - 3)*(2*n - 4)/(4*n^2 - 6*n + 3))))) for n >= 3. Taking the limit gives the continued fraction representation sinh(1) = A073742 = 1 + 1/(6 - 6/(21 - 20/(43 - ... - (2*n - 3)*(2*n - 4)/((4*n^2 - 6*n + 3) - ...)))). (End)

V3-001573 | OEIS-A051602

a(n) is the maximal number of squares that can be formed from n points in the plane.

Values for n <= 9 [now 16] are exact and are the same for a and b (see proofs below by Hugo van der Sanden and Benoît Jubin for n <= 7 and Sascha Kurz for n <= 9, which furthermore classify all optimal configurations for these values). Values for n > 9 are conjectural since they were obtained by exhaustive search for grid points within a square of side ceil(sqrt(n)), which is a reasonable assumption. A proof that optimal configurations (with gcd of side lengths equal to 1) have a diameter at most f(n) with f of moderate growth would permit exact computation of values from exhaustive searches. Conjecture: the asymptotic density of the numbers n such that there is no maximal arrangement formed by all the grid points within a suitably chosen circle, is 0. - _Peter Munn_, Sep 30 2021 For the known values of a(n) (n <= 17), there is a maximal arrangement formed using circles as specified by the conjecture above. For n <= 100 no arrangement has yet been found to contain more squares than the best attained using a circle as specified by A348469. - _Peter Munn_, Nov 12 2021

V3-001582 | OEIS-A051909

Subset of strict Egyptian numbers - there is a unique representation of 1 as the sum of distinct unit fractions with the sum of denominators being these numbers.

McCranie conjectured that the sequence is finite. He was right. Numbers 92-269 all have at least two representations without 15 appearing among the reciprocals (list attached). In the same way that Graham did for strict Egyptian numbers, we can transform each representation (a_n) into an even (2, (2a_n)) and an odd (3, 9, 30, 45, (2a_n)). Because there are no 15's in the original representations, the odd transformation has distinct unit fractions. The same is trivially true for the even transformation because there are no 1's either. So if the original sum is s, the new sums are 2s+2 and 2s+87. 2*92+2 = 186, so the even sums can be obtained from transformations after that. 2*92+87 = 271, so the same holds for odd sums from that point. And as the pairs of original representations were distinct, so are the transformed pairs.

V3-001613 | OEIS-A053289

First differences of consecutive perfect powers (A001597).

Michel Waldschmidt writes: Conjecture 1.3 (Pillai). Let k be a positive integer. The equation x^p - y^q = k where the unknowns x, y, p and q take integer values, all >= 2, has only finitely many solutions (x,y,p,q). This means that in the increasing sequence of perfect powers [A001597] the difference between two consecutive terms [the present sequence] tends to infinity. It is not even known whether for, say, k=2, Pillai's equation has only finitely many solutions. A related open question is whether the number 6 occurs as a difference between two perfect powers. See Sierpiński [1970], problem 238a, p. 116. - _Jonathan Vos Post_, Feb 18 2008

V3-001615 | OEIS-A053392

a(n) is the concatenation of the sums of every pair of consecutive digits of n (with a(n) = 0 for 0 <= n <= 9).

The Blomberg link asks whether a number n can have more than 10 predecessors, i.e. values of p such that a(p) = n. The answer is no, because there can be at most one predecessor ending with any given digit d. That can be proved by induction by observing that d and the last digit of n determine the last 1-or-2-digit sum in the concatenation of sums forming n, and hence the penultimate digit of p. That is either incompatible with the known value of n, or it tells us what the last digit of p' is, where p' = p with its last digit removed. We also know that p' is the predecessor of n' = n with its known last digit sum removed, and so we know there is at most one solution for p' by inductive hypothesis, and hence at most one solution for p. - _David J. Seal_, Nov 06 2019

V3-001624 | OEIS-A053624

Highly composite odd numbers: odd numbers where d(n) increases to a record.

Conjecture: all terms after the first three terms are congruent to 5 mod 10. - _Harvey P. Dale_, Jul 05 2023 Dale's conjecture is correct. a(n) can't be even, since then a(n)/2 would be a smaller number with the same number of odd divisors. The respective powers of the successive odd primes can't increase, since if they did, swapping them would give a smaller number with the same number of divisors, e.g., 3^2 * 5^4 has the same number of divisors as 3^4 * 5^2, and the latter is smaller. As such, every a(n) must be an odd multiple of 5, hence congruent to 5 mod 10, unless it's simply a power of 3. But multiplying a power of 3 by 3 gives just one more divisor while multiplying a power of 3 by 5 doubles the number of divisors, so after a(n) = 9 all a(n) must be congruent to 5 mod 10, i.e., have a rightmost decimal digit of 5.

V3-001642 | OEIS-A054391

Number of permutations with certain forbidden subsequences.

Conjecture: Also the number of non-capturing set partitions of {1..n}. A set partition is capturing if it has two blocks of the form {...x...y...} and {...z...t...} where x < z and y > t or x > z and y < t. This is a weaker condition than nesting, so for example {{1,3,5},{2,4}} is capturing but not nesting. The a(0) = 1 through a(4) = 14 non-capturing set partitions are: The above conjecture is true: A partition is

non-capturing iff its representation in canonical sequential form avoids the patterns 1221 and 2112. In the context of these partition representations, the pattern 2112 is equivalent to the pattern 12112. Partitions whose canonical sequence form avoid 1221 and 12112 are one of the classes that are handled in the Mansour/Shattuck "Pattern Avoiding Partitions,..." paper. It shows that they are counted by this sequence. - _Christian Sievers_, Oct 29 2024 G.f.: 1/(1-x-x^2/(1-2x-x^2/(1-x-x^2/(1-x-x^2/(1-x-x^2/(1-x-x^2/(1-... (continued fraction) (conjecture). - _Paul Barry_, Jan 19 2009

V3-001653 | OEIS-A054767

Period of the sequence of Bell numbers A000110 (mod n).

a(2^s) = 3*2^s for s >= 2 (Theorem 6.4 in the Lunnon article). For an odd prime p, if a(p) = (p^p-1)/(p-1) (which is conjectured to hold for all p), then a(p^s) = p^(s-1)*(p^p-1)/(p-1) (Theorem 6.2 in the Lunnon article). - _Jianing Song_, Jun 18 2025

V3-001654 | OEIS-A054770

Numbers that are not the sum of distinct Lucas numbers 1,3,4,7,11, ... (A000204).

Conjecture: this is the sequence of numbers for which the base phi representation includes phi itself, where phi = (1 + sqrt(5))/2 = the golden ratio. Example: let r = phi; then 6 = r^3 + r + r^(-4). - _Clark Kimberling_, Oct 17 2012 This conjecture is proved in my paper 'Base phi representations and golden mean beta-expansions', using the formula by Wilson/Agol/Carlitz et al. - _Michel Dekking_, Jun 25 2019 a(n) = floor(((5+sqrt(5))/2)*n)-1 (conjectured by _David W. Wilson_; proved by Ian Agol (iagol(AT)math.ucdavis.edu), Jun 08 2000)

V3-001655 | OEIS-A054783

(n^2)-th Fibonacci number.

The sequence (5*a(n+1))_{n>=1} = (5, 15, 170, 4935, ...) is realizable in the sense that there is a self-map on a set T:X->X with the property that a(n) = #{x in X:T^nx=x} for all n >= 1. This is the simplest illustrative example of two different phenomena. The Fibonacci sequence sampled along an odd power cannot be made realizable after multiplication by a constant; the Fibonacci sequence sampled along an even power becomes realizable after multiplication by 5 (the discriminant of the sequence). This is now known to be an instance of a more general phenomenon in the following sense. If (a(n)) is a linear recurrence sequence whose characteristic polynomial F has simple zeros then the sequence (Ma(n^s)) satisfies the Dold congruence, where M=|discriminant(F)| and s is an integer multiple of the exponent of the Galois group of the splitting field of F over the rationals. Under an additional hypothesis on the signs of the coefficients of F, the sequence (Ma(n^s)) is realizable. - _Thomas Ward_, May 06 2022

V3-001656 | OEIS-A054872

Number of (12345, 13245, 21345, 23145, 31245, 32145)-avoiding permutations.

Conjectured to be the number of permutations of length n+1 avoiding the partially ordered pattern (POP) {5>1, 1>2, 1>3, 1>4} of length 5. That is, conjectured to be the number of length n+1 permutations having no subsequences of length 5 in which the fifth element is the largest and the first element is the next largest - _Sergey Kitaev_, Dec 13 2020 This conjecture has been proven. There are six sets of permutations avoiding six size five permutations including the two sets discussed in this sequence that are known to match this sequence. A further two are conjectured to match this sequence. - _Christian Bean_, Jul 23 2024

V3-001692 | OEIS-A055272

First differences of 7^n (A000420).

Conjecture in "Introduction à la théorie des nombres" by J. M. Deconinck and Armel Mercier: this is the period length of the fraction 1/7^n. For example 1/7^2=0.02040816326530612244897959183673469387755102040....with a period of 42 digits =6*7=a(2). The period of 1/7^3 has exactly 294=a(3) digits. - _Benoit Cloitre_, Feb 02 2002 For n >= 1, the conjecture of De Koninck and Mercier cited in the comment of Feb 02 2002 holds: a(n) is the period length of the decimal expansion of 1/7^n. Indeed, 10 is a primitive root modulo 7 (see A001913), and 10^6 == 8 (mod 49), so 7 is not in A045616. By lifting theorem for primitive roots, 10 is a primitive root modulo 7^n for every n >= 1. Consequently, the multiplicative order of 10 modulo 7^n is phi(7^n) = 6*7^(n-1) = a(n). Since gcd(10, 7^n) = 1, the decimal expansion of 1/7^n is purely periodic with this period length. - _Eiver Rodríguez_, Sep 05 2026

V3-001724 | OEIS-A057005

Number of conjugacy classes of subgroups of index n in free group of rank 2.

Response from Timothy R. Walsh, Aug 01 2012: The conjecture in the previous comment is true. A combinatorial map is a connected graph, loops and multiple edges allowed, in which a cyclic order of the incident edge-ends is assigned to every node. The equivalence between combinatorial maps and topological maps was conjectured by several researchers and finally proved by Jones and Singerman. In my 1975 paper "Generating nonisomorphic maps without storing them", I established a genus-preserving bijection between hypermaps with n darts, w vertices and b edges and properly bicolored bipartite maps with n edges, w white vertices and b black vertices. A bipartite map can't have any loops; so a combinatorial bipartite map is a multigraph and it suffices to impose a cyclic order of the edges, rather than the edge-ends, incident to each node. Thus it is just the child's drawing described above by Liskovets.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-001732 | OEIS-A057083

Scaled Chebyshev U-polynomials evaluated at sqrt(3)/2; expansion of 1/(1 - 3*x + 3*x^2).

Conjecture: Let M be any endomorphism on any vector space, such that M^3 = 1 (identity). Then (1-M)^n = A057681(n) - A057682(n)*M + z(n)*M^2, where z(0) = z(1) = 0 and, apparently, z(n+2) = a(n). - _Stanislav Sykora_, Jun 10 2012 By the conjecture: Start with x(0)=1, y(0)=0, z(0)=0 and set x(n+1) = x(n) - z(n), y(n+1) = y(n) - x(n), z(n+1) = z(n) - y(n). Then a(n) = z(n+2). This recurrence indeed ends up in a repetitive cycle of length 6 and multiplicative factor -27, confirming G. McGarvey's observation. - _Stanislav Sykora_, Jun 10 2012 a(n) = Sum_{k = 0..floor(n/3)} (-1)^k*binomial(n+2,3*k+2). Sykora's conjecture in the Comments section follows easily from this. - _Peter Bala_, Nov 21 2016

V3-001752 | OEIS-A057856

Least k such that (n+1)^k + n^k is a prime.

Conjecture: For every pair of relatively prime numbers (x, y) there exist at least one number n=2^m and one prime number p such that p = x^n + y^n. This sequence shows one case of this conjecture where y = x + 1. - _Tomas Xordan_, Jun 02 2007 The conjecture for arbitrary coprime x and y is false. Take x = 8 and y = 27. For every integer r >= 1, 8^r + 27^r = (2^r + 3^r)*(4^r - 6^r + 9^r), where the first factor is at least 5 and the second is (3^r - 2^r)^2 + 6^r >= 7. In particular, 8^(2^m) + 27^(2^m) is composite for every integer m >= 0. This does not refute the special case y = x + 1. - _Eiver Rodríguez_, Oct 01 2026

V3-001768 | OEIS-A058277

Number of values of k such that phi(k) = n, where n runs through the values (A002202) taken by phi.

Carmichael (1922) conjectured that the number 1 never appears in this sequence. Sierpiński conjectured and Ford (1998) proved that all integers greater than 1 occur in the sequence. Erdős (1958) proved that if s >= 1 appears in the sequence then it appears infinitely often. - _Nick Hobson_, Nov 04 2006

V3-001769 | OEIS-A058340

Primes p such that phi(x) = p-1 has only 2 solutions, namely x = p and x = 2p.

Conjecture: if q > 7 is in A005385, then q is in the sequence. - _Thomas Ordowski_, Jan 04 2017 Proof of conjecture: q'=(q-1)/2 is an odd prime > 3. If phi(x)=2q', which has 2-adic order 1 but is not a power of 2, there must be exactly one odd prime r dividing x. We could also have a factor of 2 (but no higher power, which would contribute more 2's to phi(x)). If x = r^e or 2r^e, then phi(x) = (r-1) r^(e-1). For this to be 2q' one possibility is r-1 = 2 and r^(e-1)=q', but then q'=r=3, ruled out by q > 7. The only other possibility is r-1=2q' and e=1, which makes r=q and x=q or 2q. - _Robert Israel_, Jan 04 2017

V3-001787 | OEIS-A059259

Triangle read by rows giving coefficient T(i,j) of x^i y^j in 1/(1-x-x*y-y^2) = 1/((1+y)(1-x-y)) for (i,j) = (0,0), (1,0), (0,1), (2,0), (1,1), (0,2), ...

Conjecture: every second column of this triangle is identical to a column in the square array A071921. For example, column 4 of A059259 (1, 3, 9, 22, 46, ...) appears to be the same as column 3 of A071921; column 6 of A059259 (1, 4, 16, 50, 130, 296, ...) appears to be the same as column 4 of A071921; and in general column 2k of A059259 appears to be the same as column k+1 of A071921. Furthermore, since A225010 is a transposition of A071921 (ignoring the latter's top row and two leftmost columns), there appears to be a correspondence between column 2k of A059259 and row k of A225010. - _Mathew Englander_, May 17 2014 See the Edwards-Allen 2020 paper, page 14, for proof of Englander's conjecture. - _Michael De Vlieger_, Dec 10 2020

V3-001815 | OEIS-A059929

a(n) = Fibonacci(n)*Fibonacci(n+2).

The preceding conjecture is true. Proof: For n >= 1 let c(n) := confrac(repeat(1^{n-1}, 2)) where 1^{k} denotes 1 taken k times. This can be computed, e.g. from [Perron, third and fourth eq. on p. 62], as c(n) = (F(n) + sqrt(F(n+1)^2 - (-1)^n)) / F(n+1), which is the conjectured formula because F(n+1)^2 - (-1)^n = a(n). - _Wolfdieter Lang_, Jan 05 2019

V3-001837 | OEIS-A060330

Primes that are the sum of five consecutive composite numbers.

Conjecture: all these primes are isolated primes (A007510). - _Davide Rotondo_, Dec 31 2024 Stronger conjecture: all p are 7 or 23 mod 30. - _Charles R Greathouse IV_, Jan 21 2025 Above conjectures are true. Proof sketch: n + n+1 + n+2 + n+3 + n+4 = 5n+10, so there must be at least one prime sandwiched between the five composite numbers. If p and p+4 are prime, then p-1 + p+1 + p+2 + p+3 + p+5 = 5p + 10 is composite. If neither p-2 nor p+2 are prime, the sums p-4 + p-3 + p-2 + p-1 + p+1, etc., are 5p-9, 5p-3, 5p+3, and 5p+9 which are even for p > 2 (and p = 2 does not work). So we must have p and p+2 prime, which yield p-3 + p-2 + p-1 + p+1 + p+3 = 5p-2, p-2 + p-1 + p+1 + p+3 + p+4 = 5p+5, and p-1 + p+1 + p+3 + p+4 + p+5 = 5p+12. 5p+5 is composite, but the others can work. Now note that the first form yields only 5p-2 = 23 mod 30 and the second 5p+12 = 7 mod 30. - _Charles R Greathouse IV_, Jan 23 2025

V3-001844 | OEIS-A060521

Number of 3 X n grids of black and white cells, no 3 of same color vertically or horizontally contiguous.

The conjectured recursion is correct: For each n count the solutions separately where the last two rows differ in 0, 1, 2, or 3 places; a linear recursion is then readily found. The corresponding matrix has characteristic polynomial x^4 - 2 x^3 - 5 x^2 + 1, matching the recursion recursion a(n+4) = 2a(n+3) + 5a(n+2) - a(n). [From _Hagen von Eitzen_, Oct 21 2009]

V3-001848 | OEIS-A060699

a(n) = floor(A^(C^n)), where A = 2.084551112207285611..., C = 1.221.

The extension of the sequence is guaranteed by the Cramer conjecture. That is: If the needed change in Y(n) for obtaining the next prime (superior or inferior) is as maximum = (log Y(n))^2/2, then the effect on Y(n-1) is less than K*C^(2n-1)*Y(n-1)/Y(n). K = (1/2)*(log A)^2 = 0.269784 This value diminishes with n. Example: For n = 23, a change in Y(23) by 2630 only changes Y(22) by 0.0043. _Jens Kruse Anderson_ with A = 2.084551112197624209091521123 calculated Y(n) = floor(A^(C^n)) from n = 1 to n = 3, obtaining 22 different primes. - Luis Rodriguez-Torres (ludovicusmagister(AT)yahoo.com), Feb 10 2009

V3-001878 | OEIS-A061652

Even superperfect numbers: 2^(p-1) where 2^p-1 is a Mersenne prime (A000668).

It is conjectured that there are no odd superperfect numbers, in which case this coincides with A019279.

V3-001881 | OEIS-A062049

Integer part of geometric mean of first n primes.

For large n, the ratio prime(n)/a(n) tends to e (very slowly). This was conjectured by Anton Vrba in 2010 (see Rivera, 2010) and proved by Sandor and Verroken (2011). Tighter bounds and asymptotics for a(n) are proved in the note "On the geometric mean of the first n primes" (2016) (see links). Better formulas prime(n)/a(n) ~ exp(1 + several terms A233824(k) / log^k(prime(n))) exist for larger n; see examples in the formula section. - _Alexei Kourbatov_, Feb 27 2016.

V3-001892 | OEIS-A062647

Numbers k such that 81^k - 80^k is prime.

Factors of these numbers are of the form p = 2*n*k + 1, just like the repunit numbers, but the PRP tests are significantly slower since there is not a fast mod() property like the repunits, where (number mod Rn) can be calculated with a folding of the digits at length n in base b. However, numbers of this form b^p - (b-1)^p seem to be prime with greater relative frequency than the repunits. While the repunits have a linear fit coefficient that approaches 0.56145948 (see link below for a Generalized Repunit Conjecture), this sequence currently has a linear fit coefficient of 0.22559. - _Paul Bourdelais_, Jul 06 2023

V3-001918 | OEIS-A063116

Dimension of the space of weight 2n cusp forms for Gamma_0(48).

Conjecture: For n>=2, a(n) is the difference between the greater of successive pairs of odd triangular numbers(A000217), namely A(B(n-1)+1) - A(B(n-2)+1), where A=A000217 and B=A016813. This reduces to a(n)=2*(8*n-7) (see Formula). (1,3),(15,21) are the first consecutive pairs of odd triangular numbers, and 21-3=18, which is a(2). - _David James Sycamore_, Sep 12 2019 Conjectures from _Colin Barker_, Jun 09 2019: (Start)

V3-001965 | OEIS-A063524

Characteristic function of 1.

a(n) for 1 <= n <= 4 and conjectured for n > 4 is the number of Hamiltonian circuits in a 2n X 2n square lattice of nodes, reduced for symmetry, where the orbits under the symmetry group of the square, D4, have 1 element: When n=1, there is only 1 Hamiltonian circuit in a 2 X 2 square lattice, as illustrated below. The circuit is the same when rotated and/or reflected and so has only 1 orbital element under the symmetry group of the square.

V3-001999 | OEIS-A064653

Integers not expressible as p + q*a^2, a>1 and p, q are primes.

Dean Hickerson (Oct 12 2001) writes: I suspect that there are no more terms in the sequence. In fact, I'll make the stronger conjecture that for all n>1260, n can be written as p + q*a^2 where a is the smallest prime that does not divide n. For example, for n=10080, a=11 and we have the representation 10080 = 7297 + 23 * 11^2. Hickerson's stronger conjecture holds for n <= 10^9. Therefore, there are no other terms up to 10^9. - _David A. Corneth_, Jun 17 2019

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002002 | OEIS-A064709

Initial term of run of (exactly) n consecutive numbers with just 2 distinct prime factors.

The given terms up to a(8) = 141 are the only terms less than 10^18. To speed the search, note that any string of 6 or more consecutive numbers contains a multiple of 6 and hence must contain a number of the form 2^a * 3^b. Conjecture: 141 is the last term, because numbers with only two different prime factors get pretty rare, so having several in a row near a number of the form 2^a * 3^b is pretty unlikely. - _Joshua Zucker_, May 05 2006 Wenders's argument is incomplete because the consecutive even numbers can have the form 2^a p^b. As stated in the paper by Eggleton and MacDougall, it is still a conjecture that 9 consecutive omega-2 numbers do not exist. - _T. D. Noe_, Oct 13 2008 Eggleton and MacDougall prove that no terms exist beyond a(9) and conjecture that a(9) does not exist. - _Jason Kimberley_, Jul 08 2017

V3-002014 | OEIS-A065069

Numbers n such that Fibonacci(n) is not squarefree, but for all proper divisors k of n, Fibonacci(k) is squarefree.

This sequence is closely related to A001602(n), which gives the index of the smallest Fibonacci number divisible by prime(n). It can be shown that the index of the first Fibonacci number divisible by prime(n)^2 is A001602(n)*prime(n). This sequence is the collection of numbers A001602(n)*prime(n) with multiples removed. For example, A001602(2)*prime(2) = 12, but all multiples of 12 will generated by 6, the first number in this sequence. The Mathematica code assumes that Fibonacci numbers do not have any square primitive prime factors -- an assumption whose truth is an open question. - _T. D. Noe_, Jul 24 2003 Terms after a(12) are conjectures until the factorizations of F(1271), F(1273), etc. are completed. - _Charles R Greathouse IV_, Feb 02 2014

V3-002023 | OEIS-A065450

Make an infinite chessboard from the squares in the first quadrant; sequence gives number of squares a knight can reach in n moves starting at the origin.

The first conjecture is true: Partial sums of A047356 = b(n) = (14*(n*(n+1)) + 2*n + 5 + 3*(-1)^n)/8, since A047356(n)=(14*n+1+3*(-1)^n)/4. And b(n) has g.f. (4*x^2 + 2*x + 1)/(-x^4 + 2*x^3 - 2*x + 1). The difference a(n) - b(n) = 0,2,2,0,0,0,0,0,0..., which has g.f. 2*x^2 + 2*x. Then (4*x^2 + 2*x + 1)/(-x^4 + 2*x^3 - 2*x + 1) + 2*x^2 + 2*x = (-2*x^6 + 2*x^5 + 4*x^4 - 4*x^3 + 2*x^2 + 4*x + 1)/(-x^4 + 2*x^3 - 2*x + 1). - _Vim Wenders_, Apr 16 2008 Conjectures: G.f.: [1+6x^2+4x^3-4x^4-2x^5+2x^6]/[(1+x)*(1-x)^3]. For n>3, partial sums of A047356. - _Ralf Stephan_, Mar 06 2004 The second conjecture "For n>3, partial sums of A047356" is also true. From the last possible move, we can either move back to the second last possible move or to b(n)=A047883(n) new squares. So a(n) = a(n-2)+b(n). For n>6, b(n)=7(n-1)+4=A017029(n-1). But a number of the form 7n+4 is naturally the sum of two consecutive terms in A047356 (4=1+3,11=3+8,18=8+10, ...). The conjecture follows. - _Vim Wenders_, Apr 12 2008

V3-002027 | OEIS-A065657

Numbers m that minimize | k / EulerPhi(k) - golden ratio phi | when k runs over all the numbers with the same number of digits as m.

Since phi is irrational, n/EulerPhi(n) can only approximate phi. Probably an open question: can |(n/EulerPhi(n)) - phi| be made arbitrarily close to 0? The listed terms have this property: for r = 1,...,5, all r-digit terms share the same set of prime factors. For example, all three 3-digit terms have prime factors 3 and 13. Furthermore, all listed terms are multiples of 3. I conjecture that these properties hold in general.

Alternating sum of digits of n^2.

Conjecture; there are an infinite number of values which do not appear in this sequence (in the signed version, of course). The first example appears to be 2. _Sean A. Irvine_ has checked this up to 10^9. - _Robert G. Wilson v_, Dec 10 2001 a(n) == n^2 (mod 11). In particular, values == 2, 6, 7, 8, 10 (mod 11) do not appear, and the conjecture is true. - _Robert Israel_, Oct 24 2017

V3-002044 | OEIS-A065941

T(n,k) = binomial(n-floor((k+1)/2), floor(k/2)). Triangle read by rows, for 0 <= k <= n.

For example, for N = 11, we get: (1, 2, 4, 3, 5), showing that when confronted with two choices after the 4: (8 and -3), pick the smaller (abs) term, = 3. Then for the next row pick 7 (not used) and repeat the algorithm; succeeding only if the trajectory produces new terms. But 7 is also (-4) mod 11 and 4 was used. Therefore what I call the "r-t table" (for roots trajectory) has only one row: (1, 2, 4, 3, 5). Conjecture: The numbers of terms in the first row is equal to A003558 corresponding to N, i.e., 5 in this case with period 2.

V3-002056 | OEIS-A066357

Number of ordered (i.e., planar) trees on 2n edges with every subtree at the root having an even number of edges.

These numbers have the same parity as the Catalan numbers C(n), that is, a(n) is even except when n has the form 2^m - 1. This follows immediately from the formula a(n) = C(2*n+1) + 2*C(2*n) - 2^(2*n + 1)*C(n) given below by Callan. We conjecture that a(n) and C(n) have the same 2-adic valuation (checked up to n = 100). - _Peter Bala_, Aug 02 2016 The conjecture above is true. Let C(n) denote the n-th Catalan number and let s_2(n) denote the binary digit sum. From C(n) = binomial(2*n,n)/(n+1) and Kummer theorem, v_2(C(n)) = s_2(n+1)-1. Using Callan formula a(n) = C(2*n+1) + 2*C(2*n) - 2^(2*n+1)*C(n), the three terms have 2-adic valuations s_2(n+1)-1, s_2(n)+1, and 2*n+s_2(n+1), respectively. Since s_2(n+1) <= s_2(n)+1, the first valuation is strictly smaller than the other two. Hence v_2(a(n)) = s_2(n+1)-1 = v_2(C(n)) for all n >= 0, proving the conjecture. - _Clément Garrot_, Sep 13 2026

V3-002073 | OEIS-A066817

Conjectured values of first prime in the orbit f(m), f(f(m)), ..., where f(n) = A067599(n) and m = n-th composite number; or 0 if none exists.

Conjectured values of first prime in the orbit f(m), f(f(m)), ..., where f(n) = A067599(n) and m = n-th composite number; or 0 if none exists. The terms with 0 value listed above are conjectural. There are no primes < 10^30.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Joseph L. Pe_, Feb 01 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002074 | OEIS-A066831

Numbers k such that sigma(k) divides sigma(phi(k)).

But suppose n=2m, m odd: again with phi(2m)=phi(m) and sigma(2)=3, sigma(phi(2m)) / sigma(2m)=3 => sigma(phi(m)) /3sigma(m)=3 => sigma(phi(m)) / sigma(m)=9; and with sigma(4)=7 sigma(phi(4m))/ sigma(4m)=1 => sigma(2phi(m))/7sigma(m)=1 => sigma(2phi(m))/ sigma(m)=7. So we get the condition sigma(phi(m)) / sigma(m)=9 <=> sigma(2phi(m))/ sigma(m)=7 which will fail. So if there is a (very) big odd number n in A066831 (numbers n such that sigma(n) divides sigma(phi(n))) with A066831(n) = 9, the conjecture is wrong. I admit I could not yet find such a number, nor do i really know it exists, i.e., A067385(9) exists. (End)

V3-002080 | OEIS-A066883

Number of primes in the interval [p(n), p(n)^2] minus p(n), where p(n) is the n-th prime.

Haga's conjecture (see link below) is that if the integers from 1 to p^2 (p prime) are put in a p by p square in standard order, then there's a transversal consisting of primes; i.e., a set of p primes containing exactly one number in each row and column. E.g., for p=5 the primes 5, 7, 11, 19, 23 work. Since p is needed for the p-th column, primes less than p can't be used. a(n) is the number of primes available minus the number needed for the transversal.

V3-002088 | OEIS-A067069

Numbers n such that for every k the following condition holds: (*) The number of nonnegative solutions of the Diophantine equation x^2 + n*y^2 = 1+n*k^2 equals one half of the number of divisors of 1+n*k^2 if 1+n*k^2 is not a square and one half of 1 + the number of divisors of 1+n*k^2 if 1+n*k^2 is a square.

The sequence is conjectural. It depends on a proof of conjecture 1: If condition (*) holds for k and n < u(k), then it holds for k+1 and n, where u(k) is some nondecreasing function of k. Computationally this is confirmed for 1 < k < 300 and n < 100, 2 < k < 250 and n < 238, 3 < k < 250 and n < 282, 5 < k < 200 and n < 652, 8 < k < 200 and n < 2088, 9 < k < 200 and n <= 1000000. No further terms up to 1000000 were found; this suggests conjecture 2: The sequence is finite and 1848 its last term. Perhaps easier to prove is the stronger conjecture 3: For every n > c there is a k < d such that condition (*) is violated for k and n. Computationally this is confirmed for n <=1000000 and c = 1848, d = 11.

V3-002098 | OEIS-A067368

a(n) is the smallest positive even integer that cannot be expressed as the product of two or three previous terms (not necessarily distinct).

Conjecture: a(n) = a(n-1) + 2 if (n = 2a(k) + k + 1) or (n = 2a(k) + k) for some k, otherwise a(n) = a(n-1) + 4. This has been confirmed for several hundred terms. The above conjecture is correct because there are 2*(a(k+1)-a(k)) terms that are not divisible by 4 in the k-th interval which are determined by terms that are divisible by 4. For example, there are 2*(a(2)-a(1)) = 2*(6-2) = 8 terms between a(5) = 16 and a(14) = 48 because numbers of the form 2*s are always terms where s is an odd number. So first differences of a(n) determine the corresponding intervals and the formula above always holds. - _Altug Alkan_, Sep 24 2018

V3-002113 | OEIS-A067742

Number of middle divisors of n, i.e., divisors in the half-open interval [sqrt(n/2), sqrt(n*2)).

The proofs are straightforward. These results were conjectured by _Omar E. Pol_ in 2017. (End) Conjecture 1: This is the central column of the isosceles triangle of A249351. Conjecture 2: a(n) is also the width of the terrace at the n-th level in the main diagonal of the pyramid described in A245092. Conjecture 3: a(n) is also the number of central subparts of the symmetric representation of sigma(n). For more information see A279387. Conjectures 2 and 3 were proposed after _Michel Marcus_'s conjecture in A237593. (End) Conjectures 1, 2, and 3 are all true. - _N. J. A. Sloane_, Feb 11 2021 The above conjecture is essentially the same as _Michel Marcus_'s conjecture in A237593. - _Omar E. Pol_, Dec 20 2020 Conjecture: a(n) = A082647(n) - A131576(n) = A001227(n) - 2*A131576(n). - _Omar E. Pol_, Feb 06 2017

V3-002132 | OEIS-A068133

First triangular number with digit sum = n-th triangular number.

The sum of the digits of triangular numbers in most cases is a triangular number. Conjecture: For every triangular number T there exist infinitely many triangular numbers with sum of digits = T. There exist only finitely many triangular numbers whose digit sum is T(0)=0 or T(1)=1: T(0)=0 is, of course, the only one with digit sum 0, and T(1)=1 and T(4)=10 are the only two with digit sum 1. However, for digit sums equal to each of at least the next several triangular numbers, the conjecture can be easily confirmed by observing that, e.g., T(2), T(20), T(200), T(2000), etc., all have digit sum T(2)=3; T(2+1), T(20+1), T(200+1), T(2000+1), etc., all have digit sum T(3)=6; T(20+2), T(200+2), T(2000+2), T(20000+2), etc., all have digit sum T(4)=10; and, similarly, for all sufficiently large values of j, triangular numbers of the form T(2*10^j+m), where m = 3, 9, 23, 34, 132, 368, 1332, 3943, 19388, 88248, 244948, 1788848, 9838483, 19994343, respectively, will have digit sums T(5)=15, T(6)=21, ..., T(18)=171, respectively. (End)

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002165 | OEIS-A069482

a(n) = prime(n+1)^2 - prime(n)^2.

Conjecture: The sum of prime factors with repetition (sopfr) applied to a(n), A001414(a(n)), covers all integers covered by sopfr, except 2,3,4,6,7,10,13,15. See A001414 for the sopfr sequence, which does not cover 0 and 1. - _Richard R. Forberg_, Feb 07 2015 Conjecture: There is no upper bound on the number of repetitions (i.e., size of a tally) that will occur for some a(n) values, because the number of possible ways of producing a value of a(n) grows with increasing n, despite decreasing prime density. This happens because there is increasing range in the size of prime gaps which increases the range of primes that can produce the same a(n) value much faster than the decrease in prime density which is decelerating with larger n. - _Richard R. Forberg_, Feb 17 2015

V3-002167 | OEIS-A069548

Primes of the form sum 6d/(2 + mu(d)) for some k and all d dividing k.

The function is the sum of 3d or -d (mu(d) -1 or 1, resp.) over the squarefree divisors d of n, plus 3*sigma(n). As a result, for n > 1, the squarefree part is even, and thus n generates odd numbers only when 3*sigma(n) is odd. This happens only when n is a square or twice a square, as conjectured by Alonso Del Arte. - _Charles R Greathouse IV_, Feb 18 2011

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Benoit Cloitre_, Apr 18 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002168 | OEIS-A069581

Triangle T(m,n) giving number of unit fractions (with odd denominators) needed to represent m/n, rational (n odd), using the greedy algorithm.

If m/n, a rational number (n odd) is expressed as sum (1/xi), where the xi are successively chosen to be the least possible odd integers which leave a nonnegative remainder, is the sum always finite? My conjecture: odd m needs odd, even m needs even unit fractions. In the triangle: rows are the (odd) denominators, columns are 1<m<n numerators.

V3-002184 | OEIS-A069941

Number of primes p such that n! <= p <= n! + n^2.

Conjecture: if n>=2 there are at least 3 primes p such that n!<=p<=n!+n^2 (or stronger: for n>1, a(n) > log(n)). This is stronger than the conjecture described in A037151(n). Because if n!+k is prime, k composite, k=A*B, where A and B must have, each one, at least one prime factor>n (if not: A=q*A' q<=n then n!+k is divisible by q), hence k>n^2.

Also stronger (but more restrictive) than the Schinzel conjecture: "for m large enough there's at least one prime p such that m <= p <= m + log(m)^2" since n^2 < log(n!)^2 for n>5.

V3-002185 | OEIS-A069942

Reversal of n equals the sum of the reversals of the proper divisors of n.

These numbers are called picture-perfect numbers (ppn's). If a ppn is placed on one side of an equal sign and its proper divisors on the other side, then the resulting equation read backwards is valid. The first three ppn's were found by _Joseph L. Pe_. The fourth ppn was discovered by Daniel Dockery. Mark Ganson conjectures that every ppn is divisible by 3. (Compare this with the still unresolved conjecture that every perfect number is divisible by 2.)

V3-002191 | OEIS-A070077

Greatest common divisor of n-th squarefree number and n-th cubefree number.

Conjecture: for any squarefree k exists m such that a(m)=k; see A070078.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Reinhard Zumkeller_, Apr 22 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002192 | OEIS-A070219

Smallest prime obtained as a concatenation of n and a number m greater than n.

Conjectures: There is at least one number k with n<k<2n such that the concatenation n and n+k is a prime. For all m there is at least one number k with m*n < k < (m+1)*n such that the concatenation n and n+k is a prime. As written, both conjectures are false. For n = 2, the only integer k with n < k < 2*n is k = 3, and the decimal concatenation of n and n+k is 25 = 5^2. This also refutes the second conjecture with m = 1. Updated first conjecture: the only positive integers n for which no integer k with n < k < 2*n gives a prime by concatenating n and n+k are 1, 2, 4, 5. - _Eiver Rodríguez_, Oct 07 2026

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Amarnath Murthy_, Nov 17 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002193 | OEIS-A070226

Numbers k such that the squarefree kernel of k is equal to the number of divisors of k.

Conjecture : If A000005(k) divides A007947(k) for some k, then A007947(k) = A000005(k). (End) The conjecture above is true: For any k >= 1, A001222(A000005(k)) >= A001221(k) (from the multiplicative formula for A000005). If A000005(k) divides A007947(k), then A000005(k) is squarefree, so A001221(A000005(k)) = A001222(A000005(k)) >= A001221(k). However, because A000005(k) divides A007947(k), we also have A001221(A000005(k)) <= A001221(A007947(k)) = A001221(k). Therefore, A001221(A000005(k)) = A001221(A007947(k)), and A000005(k) cannot be a proper divisor of A007947(k).

V3-002201 | OEIS-A070563

a(n) = 0 if 3 divides the Ramanujan number tau(n) (A000594(n)), otherwise 1.

Multiplicative because A000594 is. Conjecture: a(3^k) = 0, if p == 1 mod 3, a(p^2k) = 0 and a(p^(2k+1)) = 1, if p == -1 mod 3, a(p^2k) = 1 and a(p^(2k+1)) = 0. - _Christian G. Bower_, Jun 10 2005 The above conjecture is not correct. The first counterexample occurs at n = 2401 = 7^4. My improved conjecture is that this is actually a characteristic function of nonmultiples of 3 whose sum of divisors is also a nonmultiple of 3, that is, having a following multiplicative formula: a(3^k) = 0, if p == 1 mod 3, a(p^e) = 1 if e != 2 (mod 3), otherwise 0, and if p == -1 mod 3, a(p^2k) = 1 and a(p^(2k+1)) = 0. This conjecture has now been proved

correct by _Seiichi Manyama_. a(n) = A011655(n) * A353815(n), conjectured by _Antti Karttunen_, proved by _Seiichi Manyama_, Jul 03 2024

V3-002219 | OEIS-A071069

a(n) = min { A070923(k) | n^3 < k < (n+1)^3 }.

Strong conjecture : for n>12, n^2/2<a(n)<n^2. Weak conjecture : a(n)>n for any n. A simple application of the weak conjecture could be to determine if the equation x^3-y^2 = A (A integer) has no solution in integers. For example the equation x^3-y^2 = 5 would have no solution in integers since a(n)>5 for n>5 and from a direct calculus, A070923(k) is different from 5, k = 1^3 to 6^3. The strong conjecture does not hold for n = 23, 26, 28, 30, 36, 42, 46, 47, 48, 49, ... - Lambert Klasen (Lambert.Klasen(AT)gmx.net), Dec 17 2004

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002222 | OEIS-A071111

a(n) is the least integer x such that there exists an integer in the open interval (x/(i+1), x/i) for i= n-1, n-2 ..., 3, 2, 1.

"This formula was found by Florian Herzig (then a student at Cambridge, UK), who also proved that the proposer's conjecture that a(n) = cases (1 + (n-m)^2, if m^2 <= n - 2, 1 + (n-m)^2 + (n - m), otherwise) where m = floor ((1 + sqrt (4 n - 7)) / 2) also is true although 'the proof of this fact is quite challenging'.

V3-002243 | OEIS-A071536

Number of extensions to a semigroup of the (categorical) composition of arrows in the complete directed graph on n labeled nodes.

Terms obtained, especially the 147, lend some support to the peculiar conjecture that the composition in any category can be extended to a total, associative operation, that is to a semigroup (not, of course, a monoid).

猜想/问题提及段 | historical_or_current_mention_unreviewed | F. Lockwood Morris (lockwood(AT)ecs.syr.edu), May 29 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002244 | OEIS-A071537

Least integer m >= n such that there exist integers k_n, k_n+1, ..., k_m with nonzero k_n, for which n^(k_n) * (n+1)^(k_n+1) * ... * m^(k_m) = 1.

Conjecture: this is a permutation of the nonprimes A018252. The conjecture is true. It is easy to see that (i) a(n)=m cannot be prime; (ii) k_m is always nonzero; (iii) for any nonprime s, there exist integers k_p,...,k_s, where p is the smallest prime divisor of s, k_p and k_s are nonzero, for which p^(k_p)*...*s^(k_s) = 1. The bijectivity of a(n) (as a function between positive integers and nonprimes) now follows from the lemma.

V3-002265 | OEIS-A072041

a(n) is the smallest number of the form k + reverse(k) for exactly n integers k, or -1 if no such number exists.

The negative terms are conjectural. Moreover they have a rather low degree of confirmation, since due to the time-consuming computations only numbers from 0 to 65000 have been taken into account. Random tests of larger numbers however seem to indicate, that only selected values of n occur. - In the cognate sequence A071266 two numbers a and b are counted only once, if n = a + b, a = reverse(b), b = reverse(a). Then 33 = 12 + 21 = 30 + 03 has a count of 2 and 44 = 13 + 31 = 22 + 22 = 40 + 04 has a count of 3, so 44 appears in A071266 instead of 33.

V3-002283 | OEIS-A072447

Number of connectedness systems on n vertices that contain all singletons and the set of all the vertices.

Conjecture concerning the original definition: a(n) is also the number of families of subsets of {1, ..., n} that contain both the universe and the empty set, are closed under intersection and contain no sets of cardinality n-1. - _Tian

Vlasic_, Nov 04 2022. [This was false, as pointed out by _Christian Sievers_, Oct 20 2023. It is easy to see that for n>1, a(n) is also the number of families of subsets of {1, ..., n} that contain both the universe and the empty set, are closed under union of nondisjoint sets, and contain no singletons; whereas by duality, the sequence suggested in the conjecture is also the number of those families that are also closed under arbitrary union. For details see the Sievers link. - _N. J. A. Sloane_, Oct 21 2023]

V3-002285 | OEIS-A072493

a(1) = 1 and a(n) = ceiling((Sum_{k=1..n-1} a(k))/3) for n >= 2.

Is this sequence, with its first 8 terms removed, the same as A005427? See also the similar conjecture with A005428/A073941. - _Ralf Stephan_, Apr 04 2003 Conjecture 1: a(n) equals the number of multiples of 3 whose representation in base 4/3 (see A024631) has n-1 digits. For example, a(8) = 4 because there are four multiples of 3 with n-1 = 7 digits in their representation in base 4/3: 33 = 3210201, 36 = 3210230, 39 = 3210233, and 42 = 3213122. Conjecture 2: a(n) equals 1/4 times the number of nonnegative integers with the property that their 4/3-expansion has n digits (assuming that the 4/3-expansion of 0 has 1 digit). For example, a(7)*4 = 12 because the following 12 numbers have 4/3 expansions with n = 7 digits: 32 = 3210200, 33 = 3210201, 34 = 3210202, ..., 42 = 3213122, 43 = 3213123. (End) Both conjectures are correct. We first notice that the maximum number with at most n digits in its base-4/3 expansion is 4*A087192(n) - 1, and so the number of multiples of 3 having n digits is floor((4*A087192(n) - 1)/3) - floor((4*A087192(n-1) - 1)/3) = (ceiling(4*A087192(n)/3) - 1) - (ceiling(4*A087192(n-1)/3) - 1) = A087192(n+1) - A087192(n). Let f_n = A087192(n+1), with alpha = 4/3, a = 0, and b = 2/3, then we see that (A390321/4)*(4/3)^n - 1/2 < A087192(n+1) - A087192(n) < (A390321/4)*(4/3)^n + 1/2, since we have neither e_n = -1/3 for all sufficiently large n nor e_n = 1/3 for all sufficiently large n. We conclude that a(n) = A087192(n) - A087192(n-1) for n > 1 by the first formula below, confirming both conjectures. (End) Conjecture: The constant c above equals (3/16)*K(4), where K(q) = C(q/(q-1)) (q > 1) is described in Odlyzko and Wilf (1991). The conjecture above is correct. (End)

V3-002294 | OEIS-A072768

The RASTxx transformation of the sequence A072643.

Differs from A071673 first time at the position n=37, where A072768(37) = 4, while A071673(37) = 5. RASTxx(A072768) differs from A071673 first time at the position n=704, which leads to conjecture that the repeated applications of RASTxx starting from A072643 converge towards A071673, the fixed point of RASTxx transformation.

V3-002315 | OEIS-A073133

Table by antidiagonals of T(n,k) = n*T(n,k-1) + T(n,k-2) starting with T(n,1) = 1.

This results in an infinite array in which sequences above the (1, 0, 1, 0, ...) are reflections of the sequences below, except for the alternate signs. Any sequence in the (+ sign) row starting (1, n, ...) is the (2*n-th) INVERT transform of the same sequence but with alternate signs. Example: (1, 2, 5, 12, ...) is the (2*2) = fourth INVERT transform of (1, -2, 5, -12, ...) by inspection. Conjecture: This "reflection" principle will result from taking successive INVERT transforms of any aerated sequence starting 1, ... and with positive signs. Likewise, the rows above the aerated sequence are successive INVERTi transforms of the aerated sequence. - _Gary W. Adamson_, Jul 14 2019

V3-002320 | OEIS-A073310

a(n) is the smallest number k such that 2+k and 2n+k are both prime.

Conjecture: a(n) < 2n. See A073316 for a generalization for all positive even numbers less than 2n.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _T. D. Noe_, Aug 02 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002321 | OEIS-A073316

a(n) = Max d(j), j=1..n-1, where d(j) is the smallest positive number such that 2j+d(j) and 2n+d(j) are both prime. A generalization of A073310.

Conjecture: a(n) < 2n. Note that the truth of this conjecture implies that for any pair of positive even numbers e1 < e2 <= 2n, there is a positive odd number d < 2n such that e1+d and e2+d are primes. Note that this conjecture can also be stated with odd and even swapped: for any pair of positive odd numbers d1 < d2 < 2n, there is a positive even number e <= 2n such that e+d1 and e+d2 are primes. Also note that proving this conjecture would prove the twin primes conjecture. This is equivalent to a conjecture by Erdős mentioned by _R. K. Guy_ at the end of section C1 of his book. The conjecture has been verified for n < 10^5. - _T. D. Noe_, Nov 04 2007

V3-002331 | OEIS-A073631

Nonprimes k such that k divides 3^(k-1) - 2^(k-1).

All primes p>3 divide 3^(p-1) - 2^(p-1). It appears that a(1) = 1 and a(4) = 529 = 23^2 are the only perfect squares in a(n). Most terms of a(n) are squarefree. First 50 nonsquarefree terms of a(n) are the multiples of 23^2. Conjecture: All nonsquarefree terms of a(n) are the multiples of 23^2. Numbers n such that k=n*23^2 divides 3^(k-1) - 2^(k-1) are listed in A130058 = {1, 67, 89, 133, 199, 331, 617, 793, 881, 5281, 8911, 1419, 13333,...}. - _Alexander Adamchuk_, May 04 2007

V3-002353 | OEIS-A074063

a(n) is the number of essentially different ways in which the integers 1,2,3,...,n can be arranged in a sequence such that (1) adjacent integers sum to a prime number and (2) squares of adjacent numbers sum to a prime number. Rotations and reversals are counted only once.

It is known that a(n) > 0 for 58 <= n <= 200. It is conjectured that a(n) > 0 for all n > 57. A greedy algorithm can be used to quickly find a solution for many n. See the link to puzzle 189 for more details. The Mathematica program uses a backtracking algorithm to count the arrangements. To print the unique arrangements, remove the comments from around the print statement.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002397 | OEIS-A075432

Primes with no squarefree neighbors.

This sequence is infinite by Dirichlet's theorem, since there are infinitely many primes == 17 or 19 (mod 36) and these have no squarefree neighbors. Ludovicus's conjecture about density is correct. Capsule proof: either p-1 or p+1 is divisible by 4, so it suffices to consider the other number (without loss of generality, p+1). For some fixed bound L, p is not divisible by any prime q < L (with finitely many exceptions) so there are q^2 - q possible residue classes for p. The primes in each are uniformly distributed so the probability that p+1 is divisible by q^2 is 1/(q^2 - q). The product of the complements goes to 2A as L increases without bound, and since 2A is an upper bound the limit is sandwiched between. - _Charles R Greathouse IV_, Aug 27 2014

V3-002415 | OEIS-A076099

Triangle read by rows in which the n-th row contains n numbers not occurring in the previous rows whose product is an n-th power. The first (n-1) numbers of the n-th row are the smallest number not occurring earlier and the n-th term is chosen to satisfy the requirement.

The first n-1 elements of the n-th group are the smallest n-1 numbers that haven't already appeared, say u1, u2, ..., u_(n-1) and let u_n be the unknown final element of the n-th group. Let u1*u2*u3*...*u_(n-1) = (p1^e1)(p2^e2)...(pr^er). Then u_n = product(i=1 to r) p_i^(ei + n*floor(ei/n) - n) ...unless this has already appeared in the sequence (probably this never happens). More simply, I conjecture that u_n = product(i=1 to r) p_i^(ei - n). - _Sam Alexander_, Dec 31 2003

V3-002421 | OEIS-A076337

Riesel numbers: odd numbers n such that for all k >= 1 the numbers n*2^k - 1 are composite.

509203 has been proved to be a member of the sequence, and is conjectured to be the smallest member. However, as of 2009, there are still several smaller numbers which are candidates and have not yet been ruled out (see links). Riesel numbers are proved by exhibiting a periodic sequence p of prime divisors with p(k) | n*2^k-1 and disproved by finding prime n*2^k-1. It is conjectured that numbers that cannot be proved Riesel in this way are non-Riesel. However, some numbers resist both proof and disproof. Others conjecture the opposite: that there are infinitely many Riesel numbers that do not arise from a covering system, see A101036. The word "odd" is needed in the definition because otherwise for any term n, all numbers n*2^m, m >= 1, would also be Riesel numbers, but we don't want them in this sequence (as is manifest from A101036). Since 1 and 3 obviously are not in this sequence, for any n in this sequence n-1 is an even number > 2 and therefore composite, so one could replace "k >= 1" equivalently by "k >= 0". - _M. F. Hasler_, Aug 20 2020

V3-002423 | OEIS-A076502

a(1)=1, a(n)=n-a(n-a(n-a(n-1))).

Conjecture : a(n) - c*n is bounded and a(n)=floor(c*n) + 0 + 1 or +2. The conjecture that a(n) is always one of floor(c*n), floor(c*n) + 1, or floor(c*n) + 2 is false. The first counterexample is at n = 1167, for which the recurrence gives a(1167) = 664. Let P(x) = x^3 - x^2 + 2*x - 1, and let c be its positive root. Then P(665/1167) = -9043/1589324463 < 0 and P(666/1167) = 92227/58863869 > 0. Since P'(x) = 3*(x - 1/3)^2 + 5/3 > 0 for every real x, P is strictly increasing, so 665/1167 < c < 666/1167. Hence floor(1167*c) = 665, whereas a(1167) = 664 = floor(1167*c) - 1. This does not disprove the separate conjecture that a(n) - c*n is bounded. - _Eiver Rodríguez_, Sep 16 2026

V3-002432 | OEIS-A076847

Ramanujan function tau(p) as p runs through the primes.

Note that the product representation of the Dirichlet series Sum_{n >=1} tau(n)/Sum_{n >= 1} tau(n)/n^s = Prod_{n >= 1} 1/(1 - a(n)/prime(n)^s + prime(n)^(11) / prime(n)^(2*s)) (see the Mordell reference, eq. (2)) leads also to this formula for tau(p^k) for primes p after expanding the factors of the product and collecting powers of 1/p^(k*s). If one insists on convergence of the product one can use s >= 7, if one uses Ramanujan's 1916 conjecture (proved by P. Deligne 1974) |tau(p)| <= 2*p^(11/2), i.e., |a(n)| <= 2*sqrt(prime(n)^11).

V3-002437 | OEIS-A076897

a(1)=1, a(n)=n-a(floor(3n/4)).

Conjecture: a(n) is asymptotic to 4n/7; (a(n)-4n/7)/log(n) is bounded. Conjecture is true: in fact if D(n) = a(n) - 4*n/7, D(n) = (3*n-4*m)/7-D(m) where m = floor(3*n/4), so |D(n)| <= 4/7 + |D(m)|. Thus D(n) <= 3/7 + 4/7 log_(4/3)(n).

V3-002453 | OEIS-A077202

a(1) = 1, a(n) = smallest number such that the concatenation of two successive terms gives a prime which has not occurred earlier.

Conjecture: Every odd prime occurs in this sequence infinitely many times.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Amarnath Murthy_, Nov 02 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002454 | OEIS-A077214

a(1) = 1. a(n+1) is the smallest number which is greater than a(n), coprime to it and has a different prime signature.

Subsidiary sequence: First occurrence of a difference n between successive terms. Conjecture : the maximum value of a(k+1) - a(k) = 7 that too occurs only once for k = 2.(i.e. the subsidiary sequence has only 7 terms.) I conjecture that a(n+1)-a(n) is unbounded. The simplest way to get such a gap is to find n divisible by lcm(1,2,...,k) where n+1 has the same prime signature as n. I expect that such numbers exist, although they are likely to be quite large. (Since n-1 lacks small divisors, it is very likely to be in the sequence and so n is also very likely to be in the sequence.) Note that the sequence includes every prime except 3, 5 and 7. - _Franklin T. Adams-Watters_, Jul 18 2006

V3-002469 | OEIS-A077712

a(1) = 1, a(n) = the smallest squarefree number > a(n-1) which contains all the digits of a(n-1).

Conjecture: Terms contain only two types of digits, i.e., 0 and 1. Beginning with a(3), sequence follows a regular pattern: 10^2+1, 10^2+10, 10^3+1, 10^3+10, etc. until at a(21) the pattern is disrupted by 10^11+1, which is not squarefree (see A086982). 10^12+10 is also absent from the sequence since it is also not squarefree. The pattern resumes after this disruption until the next occurrence of 10^k+1 which is not squarefree, k=21, 33, 39, 55, ... The conjecture that the sequence is composed of terms containing only the digits 0 and 1 is certainly true up to 10^406+1 where both it and 10^407+1 are not squarefree. Indeed beginning with a(3) the terms contain exactly two 1 digits and the rest 0's up to this point. The term following 10^406+10 will introduce a third nonzero digit, perhaps a 1, but the pattern of the sequence changes dramatically at this point. - _Ray Chandler_, Aug 02 2003 Term following a(739)=10^406+10 is a(740)=10^407+11 so the conjecture is still in play. - _Ray Chandler_, Aug 05 2003

V3-002484 | OEIS-A078130

Numbers having exactly one representation as sum of cubes > 1.

Conjecture: the sequence is finite; is a(63)=218 the last entry?

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Reinhard Zumkeller_, Nov 19 2002 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002485 | OEIS-A078134

Number of ways to write n as sum of squares > 1.

Conjecture (lower bound): for all k exists b(k) such that a(n)>k for n>b(k); see b(0)=A078135(12)=23 and b(1)=A078136(15)=39. This is true - see comments by _Hieronymus Fischer_. The author's conjecture holds true. Proof by induction: b(0) exists; if b(k) exists, then a(j)>k for all j>b(k). Setting m:=b(k)+1, we find that there are k+1 sums B(0,i) of squares >1, 1<=i<=k+1, with m=B(0,i). Further there are k+1 such sum expressions B(1,i), B(2,i) and B(3,i), 1<=i<=k+1, representing m+1, m+2 and m+3, respectively. For n>b(k) we have n=m+4*floor((n-m)/4)+(n-m) mod 4. A more precise formulation of the author's conjecture is "b(k):=min(n | a(j)>k for all j>n) exists for all k>=0". (End)

V3-002490 | OEIS-A078334

Primes in A005728, which counts the terms in the Farey sequence of order n.

Guy, in his Example 8, citing Leo Moser as his source, noted that the first 9 values of A005728(n) = 1 + Sum_{i=1..n} phi(i) = 1 + Sum_{i=1..n} A000010(i) are all primes, but that the pattern breaks down at A005728(10) = 33 = 3*11. As Guy warns, in several paraphrases of the same law, "Capricious coincidences cause careless conjectures." That is, for 1 <= n <= 9 we have A005728(n) = A078334(n), but for n > 9 we sometimes (n = {11, 12, 13, 15, 17, 18, 22, ...}) have A005728(n) prime, but other times (n = {10, 14, 16, 19, 20, 21, ...}) have A005728(n) composite. [_Jonathan Vos Post_, Sep 06 2010]

V3-002494 | OEIS-A078441

a(n) begins the first chain of n consecutive positive integers that have equal h-values, where h(k) is the length of the finite sequence k, f(k), f(f(k)), ..., 1 in the Collatz (or 3x + 1) problem. (The earliest "1" is meant.)

Garner (1985) conjectured that there are arbitrarily long runs of consecutive integers with the same height. As recalled by Gao (1993), the runs should have the same height, computed with f as here, and the same number of halving steps (A006666); in that form the conjecture implies that a(n) exists for every n.

V3-002510 | OEIS-A078611

Radius of the shortest interval (of positive length) centered at prime(n) that has prime endpoints.

a(1) and a(2) are undefined. Alternatively, a(n) = least k, 1 < k < n, such that prime(n) + k and prime(n) - k are both prime. I conjecture that a(n) is defined for all n > 2. Equivalently, every prime > 3 is the average of two distinct primes. a(n) embodies the difference between weak and strong Goldbach conjectures, and therefore between A047160 and A082467 which differ only for prime arguments (a(n)=A082467(prime(n)), while A047160(prime(n))=0). - _Stanislav Sykora_, Mar 14 2014

V3-002549 | OEIS-A079291

Squares of Pell numbers.

(Conjectured) For any primitive Pythagorean triple of the form (X, Y, Z=Y+1), it appears that Y or Z will always be (and only be) a square Pell number if X = A001333(n), for n > 1. If n is even, Y is always a square Pell number, and if n is odd, then Z is always a square Pell number. For example: (3, 4, 5), (7, 24, 25), (17, 144, 145), (41, 840, 841), (99, 4900, 4901). - _Jules Beauchamp_, Feb 02 2022 Conjectured formula for (X, Y, Z) for primitive Pythagorean triple of the form (X, Y, Z=Y+1) is (A001333(n)^2, A079291(n)^2, A079291(n)^2-1) or (A001333(n)^2, A079291(n)^2-1, A079291(n)^2). As a closed formula (X, Y, Z) = (((1-sqrt(2))^n + (1+sqrt(2))^n)/2, (((1-sqrt(2))^n + (1+sqrt(2))^n)^2 - 4)/8, (((1-sqrt(2))^n + (1+sqrt(2))^n)^2 + 4)/8). - _Jules Beauchamp_, Feb 02 2022

V3-002561 | OEIS-A079495

Numbers k such that the sum of the squares of the digits of k in base 3 is 0 (mod 3).

In base 2 this gives the "Evil Numbers" (cf. A001969) and slope 2. One may conjecture that in base b the asymptotic slope will be b and might suspect asymptotic density 1/b for each result (mod b). For nonprime b larger variations occur and "very big" numbers must be considered to believe in the conjecture (1 million or more...). (Related to A006287, here mod b is considered)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Carlos Alves_, Jan 20 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002562 | OEIS-A079498

Numbers whose sum of digits in base b gives 0 (mod b), for b = 3.

In base 2 this gives the "Evil Numbers" (cf. A001969). One may conjecture that in base b the asymptotic slope will be b and asymptotic density 1/b for each result (mod b). Cases b=31 or b=61 gave considerable number of primes on the sequence. Proof of this conjecture: in general, the sequence

d with terms d(n) = sum of digits of n written in base b (mod b) is a fixed point of the generalized Thue-Morse morphism 0->01..b-1, 1->12..0, etc. See A053839 for the case b=4. It follows directly from this that all symbols have asymptotic density 1/b, and therefore that the positional sequences all have asymptotic slope b. - _Michel Dekking_, Apr 18 2019

V3-002584 | OEIS-A080239

Antidiagonal sums of triangle A035317.

A different formula for a(n) as a function of the Fibonacci numbers f(n) may be conjectured. The pattern is of the form a(n) = f(p)*f(p-q) - 1 if n mod 4 = 3, else f(p)*f(p-q) where p = 2,2,4,4,4,4,6,6,6,6,8,8,8,8... and q = 0,1,3,2,0,1,3,2,0,1,3,2... p(n) = 2 * A002265(n+4) = 2*(floor((n+3)/2) - floor((n+3)/4)) (see comment by _Jonathan Vos Post_ at A002265). A general formula for sequences having period 4 with terms a,b,c,d is given in A121262 (the discrete Fourier transform, as for all periodic sequences) and is a function of t(n)= 1/4*(2*cos(n*Pi/2) + 1 + (-1)^n). r4(a,b,c,d,n) = a*t(n+3) + b*t(n+2) + c*t(n+1) + d*t(n). This same formula may be used to subtract the 1 at n mod 4 = 3. a(n) = f(p(n))*f(p(n) - r4(1,0,3,2,n)) - r4(0,0,1,0,n). - _Gary Detlefs_, Dec 09 2010

V3-002618 | OEIS-A080937

Number of Catalan paths (nonnegative, starting and ending at 0, step +/-1) of 2*n steps with all values <= 5.

Proof: (M_3)^n = b(n-2)*(M_3)^2 - (6*b(n-3) - b(n-4))*M_3 + b(n-3)*1_3, for n >= 0, with b(n) = A005021(n), for n >= -4. For the proof of this see a comment in A005021. Hence (M_3)^n[1,1] = 2*b(n-2) - 5*b(n-3) + b(n-4), for n >= 0. This proves the 3 X 3 part of the conjecture in A332602 by _Gary W. Adamson_. The formula for a(n) given below in terms of r = rho(7) = A160389 proves that a(n)/a(n-1) converges to rho(7)^2 = A116425 = 3.2469796..., because r - 2/r = 0.6920... < 1, and r^2 - 3 = 0.2469... < 1. This limit was conjectured in A332602 by _Gary W. Adamson_.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Henry Bottomley_, Feb 25 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002619 | OEIS-A080938

Number of Catalan paths (nonnegative, starting and ending at 0, step +-1) of 2*n steps with all values less than or equal to 7.

For A094256(n+1)/A094256(n), like for A094829(n+1)/A094829(n), the limit for n -> infinity is rho(9)^2 = A332438 = 3.53208888..., with rho(9) = 2*cos(Pi/9) = A332437. Therefore the formula of a(n) in terms of A094256 shows that the same limit is reached for a(n+1)/a(n). See this conjecture by _Gary W. Adamson_ in A332602.

V3-002641 | OEIS-A081352

Main diagonal of square maze arrangement of natural numbers A081349.

Conjecture: let a and b be integers such that 0 < a < b so that 0 < a/b is a proper fraction. Define the map f(a,b,D) = a/b + gcd(a,b)/D. Of course, all such a/b can be partially ordered by value, i.e., 1/2 = 0.5 < 2/3 = 4/6 = 6/9 = 0.6666... < 3/4 = 6/8 = 0.75 < 4/5 = 0.8 etc. The map f appears to specify a total strict order on the co-domain for all a/b that is consistent with the given partial order of the domain, i.e., the partial order remains intact, while equivalent fractions are given a total strict order themselves. Moreover, equivalent fractions are strictly ordered by numerator (or denominator), e.g., 1/2 < 2/4 < 3/6 etc. The conditions are that for n >= 4 all of the fractions with denominator b <= n are listed and the minimum integer value of D to achieve the total strict order of the co-domain is 2*C(n-1,2) - (-1)^(n-1). So, a(n-3) = D for n >= 4. Example: given n = 4, we have D = 2*(4-1,2) - (-1)^(4-1) = 2*3 + 1 = 7 = a(4-3) = a(1). Partial order of domain. 1/4 < 1/3 < 1/2 = 2/4 < 2/3 < 3/4. Total order of co-domain. f(1,4,7) = 1/4 + 1/7 = 33/84 < f(1,3,7) = 1/3 + 1/7 = 40/84 < f(1,2,7) = 1/2 + 1/7 = 54/84 < f(2,4,7) = 2/4 + 2/7 = 66/84 < f(2,3,7) = 2/3 + 2/7 = 68/84 < f(3,4,7) = 3/4 + 1/7 = 75/84. Observe that if D = 6, then f(2,4,6) = 2/4 + 2/6 = 10/12 = f(2,3,6) = 2/3 + 1/6. Computation shows the same failure to achieve total strict order of the co-domain for D = 2..5. (As a >= 1, then b >=2, from the above). Computation also shows that the conjecture holds for n = 4..17. - _Ross La Haye_, Oct 02 2016

V3-002649 | OEIS-A081621

Number of n-node triangulations of the sphere with minimal degree 5.

Grace conjectured that all polyhedra inscribed in the unit sphere with maximal volume are "medial" (all faces triangular and vertex degree either m or m+1 where m < 6 - 12/n < m+1). For n = 12 and n > 13 the medial polyhedra have 12 vertices of degree 5 and n-12 vertices of degree 6. The numerical solutions for n<=50 of the maximal volume problem (A081314) have this property, except for n=33. The polyhedron with conjectured maximal volume with 33 vertices is very likely a counterexample to Grace's conjecture, as it has a vertex with degree 7. See the visualization in the Pfoertner link. - _Hugo Pfoertner_, Jan 08 2026

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002676 | OEIS-A082274

Palindromes k such that k + 2 is also a palindrome.

The above conjecture is true. Adding two to the least significant digit of a number can result in a carry of at most 1, which only happens if the digit of least significance is 8 or 9. If the least significant digit is 8, adding two results in that digit becoming 0, so the resulting number can't be palindromic. If only the k least and most significant digits are 9, the least significant digit will become 1 and all other adjacent digits 9 will turn into the digit 0 and produce a carry of 1. For the starting number to have been palindromic, the k most significant digits must also be 9's. Any digits that are not 9's between the 9's will not produce a carry on their own when increased by one through the previous carry, resulting in a nonpalindromic number with some 9's as most significant digits and a single 1 and 0's as least significant digits. - _Felix Fröhlich_, Jul 22 2014

V3-002733 | OEIS-A083480

Compress the triangular array A049597 by suppressing zero entries and reversing the order of each row.

Row sums => A000041. Diagonals are sums of Gaussian polynomials (which then sum to powers of two). The number of entries on each row is conjectured to conform to: 0 1 1 1 2 2 3 3 4 5 5 6 7 7 8 9 10 10 11 12 13 13 14 15 16 17 17 ... a sequence which stutters after values 0,1,2,4,6,9,12,16,...A002620. Regarding the first element of the sequence as T(1,0), it appears that this is the number of partitions of n with k elements not in the first hook; i.e., with n - (max part size) - (number of parts) + 1 = k. If this is correct, we have T(n,0) = n and for k > 0, T(n,k) = sum_{j >= max(0,2k-n+2)} j * T(k,j). This is equivalent to T(n,k) = T(n-1,k) + sum_{j >= max(0,2k-n+2)} T(k,j) and thus to T(n,k) = 2* T(n-1,k) - T(n-2,k) + T(k,2k-n+2) [taking T(n,k) = 0 if k < 0]. It also implies the correctness of the conjecture about the row lengths. - _Franklin T. Adams-Watters_, May 27 2008

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002784 | OEIS-A084597

Largest k such that there are exactly n primes between k^2 and (k+1)^2.

a(n) is the index of last occurrence of n in A014085. This sequence relies on a heuristic calculation and there is no proof that it is correct. Conjecture: There is no k that has only one prime between k^2 and (k+1)^2.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Harry J. Smith_, May 31 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002785 | OEIS-A084611

a(n) = sum of absolute values of coefficients of (1+x-x^2)^n.

Limit_{n -> oo} a(n+1)/a(n) does not exist; however, lim_{n -> oo} a(n)^(1/n) = sqrt(5) (conjecture).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Paul D. Hanna_, Jun 01 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002786 | OEIS-A084616

Maximum number of circles of diameter 1 that can be packed in a square of area n (i.e., with side length n^(1/2)).

Most sequence terms beyond n=20 are only conjectures supported by comprehensive numerical results. No proof is available for the following observations: n=30 is the first case where a square of area < n (29.74921576) is sufficient to cover n circles. The first case where more than n circles can be covered occurs for n=38. The required area to cover 39 circles is 37.76050335. n=59 is the last case where a square of area n does not suffice to cover n+1 circles (60 circles require square area 59.11626524).

V3-002802 | OEIS-A084826

Best packing of m>1 equal spheres in a cube setting a new density record.

The terms >=31 are only conjectures found by numerical experimentation. In the table given at the Pfoertner link, the densities are given relative to the density of the cubic lattice packing (Pi/6). The first known arrangement with higher density than that of the cubic lattice packing was found for m=31 spheres. In the region 8<m<27 increasing packing densities occur for m=9,13,14. m=14 comes very close (0.994949) to the cubic lattice packing density.

V3-002804 | OEIS-A084828

Maximum number of spheres of radius one that can be packed in a sphere of radius n.

a(4) and a(5) are experimental values. Although A121346(5) claims a lower bound of a(5)=68, it is conjectured from extensive numerical search that this value is unachievable and therefore a(5)=67. The conjecture a(5)=67 was proved wrong by Yu Liang, who found an arrangement of 68 spheres of radius 1 fitting into a sphere of radius 5.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Hugo Pfoertner_, Jun 12 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002805 | OEIS-A084829

Best packing of m>1 equal spheres in a sphere setting a new density record.

All terms beyond m=9 are only conjectures found by numerical experimentation. The density is defined as the fraction of the volume of the large sphere occupied by the small spheres. For 2 spheres the density is 0.25. The first known configuration with density exceeding 0.5 occurs for 31 spheres.

V3-002808 | OEIS-A084950

Array of coefficients of denominator polynomials of the n-th approximation of the continued fraction x/(1+x/(2+x/(3+..., related to Laguerre polynomial coefficients.

Conjecture: also coefficient triangle of the denominators of the (n-th convergents to) the continued fraction w/(1+w/(2+w/(3+w/... This continued fraction converges to 0.697774657964... = Bessell(1,2)/Bessell(0,2) for w=1. For instance, the denominator of w/(1 + w/(2 + w/(3 + w/(4 + w/5)))) equals 120 + 96*w + 9*w^2. - _Wouter Meeussen_, Aug 08 2010 The continued fraction 0 + K_{k>=1}(x/k) = x/(1+x/(2+x/(3+... has n-th approximation P(n,x)/Q(n,x). These polynomials satisfy the recurrence q(n,x) = n*q(n-1,x) + x*q(n-2,x), for q replaced by P or Q with inputs P(-1,x) = 1, P(0,x) = 0 and Q(-1,x) = 0 and Q(0,1) = 1. The present array provides the Q-coefficients: Q(n,x) = sum(a(n,m)*x^m, m=0 .. floor(n/2)), n >= 0. For the P(n,x)/x coefficients see the companion array A221913. This proves the first part of W. Meeussen's conjecture given above.

V3-002835 | OEIS-A085495

Maximal order of a finite subgroup of the group GL(n,Q).

Conjecture: a(n)/2 is the maximal order of a finite subgroup of the group SL(n,Q) (or equivalently, SL(n,Z), since a finite subgroup of SL(n,Q) must be conjugate to a subgroup of SL(n,Z)). This is obviously true for odd n: given a finite subgroup G of SL(n,Q), a subgroup of GL(n,Q) of order 2*|G| can be attained by adjoining -I_n where I_n is the identity matrix. The conjecture is also correct for n = 2, since the finite subgroup of the maximal order of SL(n,Q) is isomorphic to C_6. (End)

a(0) = 1, a(2n+1) = a(n), a(2n) = a(n) + a(n-1) + ... + a(n-2^m) + ... where a(n) = 0 for n < 0.

Conjecture: all a(n) are even except a(2^k-1) = 1. Also a(2^k-2) = 2^(k-1). [For proof see link.]

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Ralf Stephan_, Jul 20 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002867 | OEIS-A086450

a(0) = 1, a(2n+1) = a(n), a(2n) = a(n) + a(n-1) + ... + a(n-m) + ... where a(n<0) = 0.

Conjecture: a(n) mod 2 repeats the 7-pattern 1,1,0,1,0,0,1 (A011657). The conjecture is easily proved by induction: a(0) to a(14) = 1, 1, 2, 1, 4, 2, 5, 1, 9, 4, 11, 2, 16, 5 read mod 2 gives 1, 1, 0, 1, 0, 0, 1, 1, 1, 0, 1, 0, 0, 1. Assume the conjecture is true up to n = 14k. Then the next 7 odd entries a(14k+1), a(14k+3), ..., a(14k+13) are read from a(7k) to a(7k+6), which follow the correct mod 2 pattern by assumption. For the even entries a(14k), a(14k+10)... a(14k+12), the sum over the first 7k-1 addends is even, simply because of each consecutive 7 addends exactly 4 are odd. So again a(7k) to a(7k+6) determines the outcome and again gives the desired pattern. a(14k) is odd, since a(7k) is odd, a(14k+2) is even, since a(7k) and a(7k+1) are odd and so on ... - Lambert Herrgesell (zero815(AT)googlemail.com), May 08 2007

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002903 | OEIS-A087107

This table shows the coefficients of combinatorial formulas needed for generating the sequential sums of p-th powers of tetrahedral numbers. The p-th row (p>=1) contains a(i,p) for i=1 to 3*p-2, where a(i,p) satisfies Sum_{i=1..n} C(i+2,3)^p = 4 * C(n+3,4) * Sum_{i=1..3*p-2} a(i,p) * C(n-1,i-1)/(i+3).

Conjectural formula for table entries: T(n,k) = Sum_{j = 0..k} (-1)^(k+j)*binomial(k,j)*binomial(j+3,3)^n. Conjecturally, the n-th row polynomial R(n,x) = 1/(1 + x)*Sum_{i >= 0} binomial(i+3,3)^n *(x/(1 + x))^n. (End) The conjectures above are correct.

V3-002918 | OEIS-A087339

Numbers k such that both the sum of the digits of k and 1 plus the product of its digits are primes.

Sequence is infinite. Proof: (10^p-1)/9 is a term if p is a prime. The sum of the digits = p and the product of digits + 1 = 2. Conjecture: There are infinitely many terms not of the form (10^p-1)/9.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002925 | OEIS-A087445

Numbers that are congruent to 1 or 5 mod 12.

Conjecture: at least one number in this sequence must appear in all Collatz sequences. The sequence is composed of all numbers in congruence classes T(n,1) mod 2^(n+k) in A259663 (i.e., T"(1) in array T259663(n,k)) not congruent to 0 mod 3. Therefore the conjecture above is true (see A259663 for additional explanation). - _Bob Selcoe_, Jul 15 2017 The above conjecture is true: this is because even numbers and odd numbers divisible by 3 will lead to the set of odd numbers not divisible by 3. Odd numbers of the form 4k - 1 can also be ignored, as this consists of odd numbers that grow between themselves and the next odd term through Collatz iteration. No infinite sequence of growth between consecutive odd terms is possible, so all numbers of the form 4k - 1 will lead to an odd number that shrinks between itself and the next odd number. All numbers 4k - 1 will lead to a number in 4k - 3, the odd numbers that shrink between themselves and the following odd term. What we are left after that elimination is this sequence. - _Aidan Simmons_, Feb 25 2019

V3-002930 | OEIS-A087552

a(1) = 1, then the smallest prime divisor of A065447(n) not included earlier.

Conjecture: Every prime is a member and this is a rearrangement of the noncomposite numbers. Proof of conjecture: primes 2=a(1) and 5=a(3) are terms, while any other prime divides infinitely many numbers of the form A002275([(n+1)/2]) = (10^[(n+1)/2]-1)/9, which in turn divide A065447(n). Thus every prime will sooner or later appear as a(n). - _Max Alekseyev_, Jul 03 2019

V3-002949 | OEIS-A087659

a(n) = hypergeom([-n, (n+4)/2, (n+5)/2], [3, 2], -4).

A few weeks ago I conjectured that 2 binomial(n,i) (n+2i+3)! / ((i+1)!(i+2)!(n+3)!) is always an integer (summed on i, this gives the current sequence). which I also conjecture integral. These conjectures are true. Consider the partition p(m,k,n)=(n+m,m,...,m) of n+m*(k+1), where m is repeated k times. It is easy to see that C(m,k,n) equals the dimension of the irreducible representation of S_(n+m*(k+1)) corresponding to p(m,k,n) calculated using hook length formula.

V3-002961 | OEIS-A087711

a(n) = smallest number k such that both k-n and k+n are primes.

Let b(n), c(n) and d(n) be respectively, smallest number m such that phi(m-n) + sigma(m+n) = 2n, smallest number m such that phi(m+n) + sigma(m-n) = 2n and smallest number m such that phi(m-n) + sigma(m+n) = phi(m+n) + sigma(m-n), we conjecture that for each positive integer n, a(n)=b(n)=c(n)=d(n). Namely we conjecture that for each positive integer n, a(n) < A244446(n), a(n) < A244447(n) and a(n) < A244448(n). - _Jahangeer Kholdi_ and _Farideh Firoozbakht_, Sep 05 2014

V3-002964 | OEIS-A087716

Base-2 pseudoprimes (see A001567) of the form j*p(i)# - p(k) or j*p(i)# + p(k), p(i) and p(k) primes with p(i) < p(k) < p(i+1)^2 and 0 < j < p(i+1).

Conjecture: sequence has only 5 terms. This has been checked for all i <= 150.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Pierre CAMI_, Sep 29 2003 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-002965 | OEIS-A087717

Start with x=n, then iterate the map x -> A322982(x) with A322982(x)=2*x-1 if x is noncomposite, otherwise A322982(x) = A032742(x), the largest proper divisor of x. If this iteration leads to a fixed point then a(n) is the value of that fixed point. If the iteration leads to a cycle, a(n) is the smallest value in the cycle. If the iteration never becomes periodic then a(n)=0.

Conjecture. For n > 1, the iteration given in the definition above always leads to the 3-cycle {3,5,9,3} or the 6-cycle {19,37,73,145,29,57,19}, thus a(n) takes on only the values 3 or 19 for n=2,3,4,.... This has been verified to n=1000000.

V3-002994 | OEIS-A088164

Wolstenholme primes: primes p such that binomial(2p-1,p-1) == 1 (mod p^4).

Primes p such that p^3 divides A001008(p-1) (Zhao, 2007, p. 18). Also: Primes p such that (p, p-3) is an irregular pair (cf. Buhler, Crandall, Ernvall, Metsänkylä, 1993, p. 152). Keith Conrad observes that for the two known (as of 2015) terms ord_p(H_p-1) = 3 is satisfied, where ord_p(H_p-1) gives the p-adic valuation of H_p-1 (cf. Conrad, p. 5). Romeo Mestrovic conjectures that p is a Wolstenholme prime if and only if S_(p-2)(p) == 0 (mod p^3), where S_k(i) denotes the sum of the k-th powers of the positive integers up to and including (i-1) (cf. Mestrovic, 2012, conjecture 2.10). - _Felix Fröhlich_, May 20 2015 The converse of Wolstenholme's theorem implies that if an integer n satisfies the congruence binomial(2*n-1, n-1) == 1 (mod n^4), then n is a term of this sequence, i.e., then n is necessarily prime, or, equivalently, A298946(i) > 1 for all i > 0. Whether this is true for all such n is an open problem. - _Felix Fröhlich_, Feb 21 2018

V3-003017 | OEIS-A088333

A version of Josephus problem: a(n) is the surviving integer under the following elimination process. Arrange 1,2,3,...,n in a circle, increasing clockwise. Starting with i=1, delete the integer 3 places clockwise from i. Repeat, counting 3 places from the next undeleted integer, until only one integer remains.

It is tempting (in view of A054995) to conjecture that a(1)=1 and, for n>1, a(n) = (a(n-1)+4) mod n. The conjecture is false; counterexample: a(21)=21; a(20)=17; (a(20)+4)mod 21=0; corrected formula: a(n)=(a(n-1)+3) mod n +1; The conjecture is true. After removing the 4th number, we are reduced to the n-1 case, but starting with 5 instead of 1. - _David Wasserman_, Aug 08 2005

V3-003023 | OEIS-A088568

3*n - 2*(partial sums of Kolakoski sequence A000002).

It is conjectured that a(n) = o(n). It is conjectured that the density of 1's and that of 2's in the Kolakoski sequence A000002 are equal to 1/2. The deficit of 2's in the Kolakoski sequence at rank n being defined as n/2 - number of 2's in

the Kolakoski word of length n, a(n) is equal to twice the deficit of 2's (or twice the excess of 1's). Equivalently, the number of 2's up to rank n in the Kolakoski sequence is (n - a(n))/2. - _Jean-Christophe Hervé_, Oct 05 2014 The conjecture about the densities of 1's and 2's is equivalent to a(n) = o(n). The graph shows that a(n) seems to oscillate around 0 with a pseudo-periodic and fractal pattern. - _Jean-Christophe Hervé_, Oct 05 2014 It is conjectured that a(n) = O(log(n)) (see PlanetMath link). Note that for a random sequence of 1's and -1's, we would have O(sqrt(n)). - _Daniel Forgues_, Jul 10 2015 The linked PlanetMath text mentions 0.5*n + O(log(n)) only in respect of an empirical observation, apparently to support the density conjecture (the conjecture described above in the first comment dated Oct 05 2014). - _Peter Munn_, Aug 03 2022 The conjecture that a(n) = O(log(n)) seems incorrect as |a(n)| seems to grow as fast as sqrt(n), see A289323 and note that a(2^n) = -A289323(n), so for example a(2^64) = -A289323(64) = -836086974 which is much larger in absolute value than log(2^64), but about 0.19*2^32. - _Richard P. Brent_, Jul 07 2017

V3-003024 | OEIS-A088601

Number of steps to reach 0 when iterating A261424(x) = x - (the largest palindrome less than x), starting at n.

While it has been conjectured [proved by Cilleruelo & Luca, 2016 -Ed.] that every number can be represented as a sum of at most 3 palindromes, the terms of this sequence, which correspond to a greedy representation, can be larger than 3 (see A109326). For example, 1022 can be represented as 33 + 989, but a(1022) = 4, because the greedy decomposition gives 1022 = 1001 + 11 + 9 + 1. - _Giovanni Resta_, Aug 20 2015 In A109326 an explicit formula for a smaller (conjectured sharp) upper bound was already given earlier. - _M. F. Hasler_, Sep 09 2018

V3-003029 | OEIS-A088643

Triangle read by rows: row n >= 1 is obtained as follows. Start with n, next term is always largest number m with 1 <= m < n which has not yet appeared in that row and such that m + previous term in the row is a prime. Stop when no further m can be found.

It is conjectured that row n is always a permutation of {1..n}. This has been verified for n <= 400000. I conjecture that almost all rows have exactly 7 (but not more) trailing terms in common with the initial terms of A055265 = (1, 2, 3, 4, 7, 6, 5, 8, ...): After row 10 whose reversal matches the first 10 terms of A055265, and rows n = 14, 15 and 16 having the last 2 (but not 3) terms equal to A055265(1..2), all rows up to n = 500 have either (about 25%) exactly 1 or (about 73%) exactly 7 trailing terms equal to the first terms of A055265. Between n = 501 and n = 10000 and beyond, all rows end in (..., 9, 14, 5, 6, 7, 4, 3, 2, 1), so they all have exactly m = 7 but not m = 8 trailing terms equal to A055265(1..m). - _M. F. Hasler_, Aug 03 2021

V3-003035 | OEIS-A088753

Numbers k such that the Reverse and Add! trajectory of k (presumably) does not reach a palindrome (with the exception of k itself) and does not join the trajectory of any term m < k.

It is not easy to determine whether the orbit of a given term will never merge into the orbit of an earlier term. It seems that the property of "disjoint orbit" is as conjectural as the property of not reaching a palindrome. One could specify a "search limit" in order to get a well-defined sequence. The given list of terms has been checked and extended by considering the orbits up to members of size <= 10^199 at least. Given that the number increases by a factor 10 roughly every 2.416 iterations, this corresponds to about 500 iterations. (End)

V3-003045 | OEIS-A088982

Primes that are between consecutive prime-indexed primes.

Conjecture: For x > 1 there is at least 1 prime between prime(prime(x)) and prime(prime(x+1)). This conjecture is equivalent to saying that there is at least one prime index between prime(x) and prime(x+1), which is trivially true because both are odd for x > 1; one has prime(prime(x)) < prime(prime(x)+1) < prime(prime(x+1)). Obviously the definition is equivalent to "primes > 2 with nonprime index", i.e., sequence A007821 without the initial 2. - _M. F. Hasler_, Jul 31 2015

V3-003046 | OEIS-A088983

Numbers k such that each of the 6 consecutive numbers k through k+5 has exactly two distinct prime factors.

This sequence has no run of four consecutive integers, since Eggleton and MacDougall prove that there are no more than 9 consecutive integers with A001221(k) = 2. They conjecture that A007774 contains no runs of 9 consecutive integers, and has only two runs of size 8 (at 141 and 212) and two maximal runs of size 7 (at 323 and 2302); they add that the maximal run of size 6 at 91 might be the only such run, so A088983 might be complete. - Roger Eggleton via _Jason Kimberley_, Jul 12 2017

V3-003061 | OEIS-A089392

Magnanimous primes: primes with the property that inserting a "+" in any place between two digits yields a sum which is prime.

Partition the digits of n into two groups by placing a '+' sign anywhere inside; the result of the expression is prime in every case. Conjecture: sequence is infinite. 11 is the largest term with all odd digits. 2 is the only member with all even digits. Observation: all two-digit primes with the most significant digit even are members. In contradiction to the above conjecture, it is rather expected that this sequence is finite, cf. the link to C. Rivera's "Puzzle 401", and G. Resta's web page. Concerning the statement about 2 and 11, one can say that all terms except 2, 11 and 101 consist of even digits followed by a final odd digit. - _M. F. Hasler_, Dec 25 2014

V3-003075 | OEIS-A089677

Exponential convolution of A000670(n), with A000670(0)=0, with the sequence of all ones alternating in sign.

Occurs also as first column of a matrix-inversion occurring in a sum-of-like-powers problem. Consider the problem for any fixed natural number m>2 of finding solutions to sum(k=1,n,k^m) = (k+1)^m. Erdos conjectured that there are no solutions for n,m>2. Let D be the matrix of differences of D[m,n] := sum(k=1,n,k^m) - (k+1)^m. Then the generating functions for the rows of this matrix D constitute a set of polynomials in n (for varying n along columns) and the m-th polynomial defining the m-th row. Let GF_D be the matrix of the coefficients of this set of polynomials. Then the present sequence is the (unsigned) second column of GF_D^-1. - _Gottfried Helms_, Apr 01 2007

V3-003096 | OEIS-A090252

The Two-Up sequence: a(n) is the least positive number not already used that is coprime to the previous floor(n/2) terms.

Conjecture 1. A090252 is a subsequence of A354144 (prime powers and semiprimes). Conjecture 2. The terms of A354144 that are missing from A090252 are 6, 10, 14, 15, 22, 33, 34, 35, 38, 39, 46, 51, 58, 62, 65, 69, 74, 77, 82, 86, 87, 91, 93, 94, 95, 106, 111, 115, 118, 119, 122, 123, 129, 133, 134, 141, 142, 143, 145, 146, 155, 158, 166, 177, 178, 183, 185, 187, 194, 201, 202, 203, 209, 213, 214, 215, 218, 219, 221, ... Conjecture 3. For a prime p, there are constants v_1, v_2, ..., v_K and c such that (This sequence of lambdas does not seem to have any simpler explanation, is not in the OEIS, and cannot be since the terms shown are all conjectural.) Conjecture 2 is a consequence of Conjecture 3. For example, 6 does not appear in A090252, since the sets S_2 and S_3 are disjoint. Assuming the numbers that appear to be missing (see Conjecture 2) really are missing, the numbers that take a record number of steps to appear are 1, 2, 3, 4, 7, 8, 16, 26, 32, 64, 128, 206, 256, 478, 512, 933, ..., and the indices where they appear are 1, 2, 3, 5, 6, 11, 23, 47, 95, 191, 383, 767, 1535, 3071, 6143, 8191, ... These two sequences are not yet in the OEIS, and cannot be added since the terms are all conjectural. If we consider the May 23 2022 comment, note the conjectured indices show near complete overlap with terms of A081026: 1, 2, 3, 5, 6, 11, 23, 47, 95, 191, 383, 767, 1535, 3071, 6143, 8191. - _Bill McEachen_, Aug 09 2024

V3-003111 | OEIS-A090496

Ratio of numerator(Bernoulli(2*n)/(2*n)) to numerator(Bernoulli(2*n)/(2*n*(2*n-1))) for n's for which they are different.

All values yielding 37 are of the form 574+666*k, k=0,1,2,3,4,... and form thus an arithmetic progression with step 666=18*37=((37-1)/2)*37. All values yielding 59 are of the form 1269+1711*k, k=0,1,2,3 and 1711=28*59=((59-1)/2)*59. The two values yielding 67 are at distance 2211=((67-1)/2)*67. Conjecture: all indices yielding a given prime p form an arithmetic progression of step ((p-1)/2)*p. See A092291. - _Roland Bacher_, Feb 04 2004 Roland Bacher conjectures that values of n yielding the same quotient p form an arithmetic progression n0+d*k, where d = p(p-1)/2. Actual and conjectured values of n0 are in the sequence A092291. Composite values do occur. An example is 2n = 272876, which yields a quotient of 37*59. This was found by tdn using the Kummer congruences and CRT: using the irregular pairs (37,32) and (59,44), we know that the following Diophantine equations must be solved for (k,l,m): 32+36*k = 44+58*l = 1+37*59*m. Some quotients are not possible, e.g., 37*67, 37*103. All quotients are the product of irregular primes A000928. Composite quotients imply there are missing terms in the arithmetic progression conjectured by Bacher. - _T. D. Noe_, Feb 12 2004

V3-003112 | OEIS-A090518

Primes arising in A090517, or 0 if A090517(n) = 0.

Conjecture: No term is zero. The conjecture is true. For every n >= 1, k = 5*10^(n-1) gives floor(10^n/k) = 2, which is prime. Hence the set of admissible k is nonempty, so A090517(n) is well-defined. The corresponding quotient A090518(n) is prime by definition and therefore nonzero. - _Lien-Hung Su_, Oct 01 2026

V3-003115 | OEIS-A090521

Least k such that floor(n!/k) is prime.

Conjecture: There exists a number k such that for all n > k, a(n) is prime. Motivation: If p is the least prime >n then all the numbers from n to p-1 divide n!. And most of the numbers from p+1 to q also divide n! where q is the least prime > p, etc. and the dividend is composite in almost all cases. I conjecture the opposite: there are infinitely many composites in this sequence. Indeed, heuristics suggest the composites may be of density 1. - _Charles R Greathouse IV_, Apr 07 2013

V3-003120 | OEIS-A090527

Smallest prime p such that floor((n^n)/p) is prime, or 0 if no such number exists.

Conjecture: No term is zero. As long as p(j+1)/p(j) < 2 for all j, then for any integer n >= 4, there exists at least one p such that p and floor(n/p) are both prime. (I do not know a proof for the premise above; however, it seems quite weak compared to other conjectures and theorems about primes. It may be that it follows from the results in sequence A038458.) In fact, there exists a prime p such that either floor(n/p) = 2 or floor(n/p) = 3. Outline of proof: (1) If p is a prime number, then for all n with 2p <= n < 3p, floor(n/p) = 2, which is prime. (2) In addition, for all n with 3p <= n < 4p, floor(n/p) = 3, which is prime. So for any n >= 4, consider the largest prime, p, with 2p <= n. (3) floor(n/p) can't be less than 2, since 2 <= n/p. (4) If floor(n/p) = 2, then p and floor(n/p) are both prime, so we are done. (5) Similarly, if floor(n/p) = 3, we are done. The only remaining case is that 4p <= n. Let p_1 be the next prime after p. (6) p_n must not meet 2(p_1) <= n, since p is the largest that does. Therefore 2(p_1) > n. (7) 4p <= n < 2(p_1) (8) (p_1 / p) > 2 (9) As long as p(j+1)/p(j) < 2 for all j, the case of 4p <= n is not possible. - Weston Markham (WMarkham(AT)paradigmgenetics.com), Jun 15 2004

V3-003136 | OEIS-A090975

Least integer k such that n!+1-k is prime.

The (n-1) consecutive numbers n!+2,...,n!+n (for n>=2) are not prime. This fact implies that there are arbitrarily large gaps in the distribution of the prime numbers. n!+1 itself may be a prime number as in the case of n=3, 11, 27 (see A002981 for all such n). Now a(n) measures, when the first prime number previous to n!+2 appears. Thus a(n)=8 means that n!+1-3 is prime and so on. Obviously, the values of a(n) are always even numbers. Conjectures: |a(n)-1| is either 1 or a prime number. Is the growth of b(n) := sum(a(k),k=0..n) quadratic, that is b(n)=O(n^2)?

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003141 | OEIS-A091182

Number of ways to write n = x + y (x >= y > 0) with xy - 1 and xy + 1 both prime.

Conjecture: a(n) > 0 for all n > 3120. This has been verified for n up to 5*10^7. Note that if x >= y > 0 and x+y = n then n-1 = x+y-1 <= xy <= ((x+y)/2)^2 = n^2/4. So the conjecture implies that there are infinitely many twin primes. More generally, we have the following conjecture: Let m be any positive integer. If n is sufficiently large and (m-1)n is even, then we can write n as x+y, where x and y are positive integers with xy-m and xy+m both prime. This general conjecture implies that for any positive even integer d there are infinitely many primes p and q with difference d. (End)

V3-003146 | OEIS-A091361

Numbers n such that A001840(n) == 0 (mod n).

Apart from 1 and 2 it is conjectured that the only values present are congruent to 3 mod 6 (all these values are present). Proof of the conjecture that this is 1 and 2 followed by A016945 follows by considering the 6 cases n=6k-1, 6k, 6k+1, 6k+2, 6k+3 or 6k+4, individual evaluation of A001840(n) with their corresponding 3 formulas quoted in A001840 in each case and searching for solutions of the form A001840(n) = t*n for integer t. G.f.: conjecture: 2*(1+x)/(1-x)/G(0) +x, where G(k)= 1 + 1/(1 - x*(3*k+1)/(x*(3*k+4) + 1/G(k+1))); (continued fraction). - _Sergei N. Gladkovskii_, Jun 06 2013

V3-003150 | OEIS-A091508

Least k such that b(k) = 1, where b(1) = n and b(k+1) = b(k)+k+1 if gcd(k+1, b(k)) = 1 or else b(k)/gcd(k+1, b(k)).

I conjecture a(n) always exists. That means sequence (b(k)) becomes ultimately regular for any n. i.e. there is always k0 such that b(k0) = 1, so b(k0+1) = b(k0) + k0 = k0 + 1 since gcd(k0, b(k0)) = 1 and gcd(k0+1, b(k0+1)) = k0+1 implies b(k0+2) = b(k0+1)/(k0+1) = 1 and from that point k0 sequence (b(k)) continues : 1, k0+1, 1, k0+2, 1, k0+3,1,... and is "regular". Benoit's conjecture is true for all n <= 10^15. (End)

V3-003155 | OEIS-A091540

Rescaled second column A091539 of array A091534 ((5,2)-Stirling2).

The recurrence conjectured by _R. J. Mathar_ on Jul 15 2026 follows from the triple factorial formula. Put q(n) = Product_{j=0..n-1} (3*j+1). Then a(n) = (3^n*n! - 3*q(n))/6, so a(n) - 3*n*a(n-1) = q(n-1) for n >= 3. Since q(n-1) = (3*n-5)*q(n-2), we obtain a(n) - 3*n*a(n-1) = (3*n-5)*(a(n-1) - 3*(n-1)*a(n-2)) for n >= 4. Rearranging gives a(n) = (6*n-5)*a(n-1) - 3*(n-1)*(3*n-5)*a(n-2), as conjectured. - _Eiver Rodríguez_, Sep 20 2026 Conjecture D-finite with recurrence a(n) +(-6*n+5)*a(n-1) +3*(n-1)*(3*n-5)*a(n-2)=0. - _R. J. Mathar_, Jul 15 2026

V3-003167 | OEIS-A091752

Generalized Stirling2 array (-1,2)S2. Irregular triangle a(n, m) for n >= 1 and 2 <= m <= 2*n.

For the case of the (irregular) triangles (-1,s)S2, for s >= 1, W. Schulte conjectured that a(s; n, m) = T(s; (s+1)*n - m - 1, m - s), for n > = 1 and m = s, s+1, ..., s*n, with the row polynomials RT(s; n, x) = Sum_{m = 0..s*n} T(s; n, m)*x^m of the triangle T(s), n >= 0, defined by the Rodrigues-type formula exp(x^(s+1)/(s+1)) (d/dx)^n exp(-x^(s+1)/(s+1)) = (-1)^n*RT(s; n, x). Thus the rows of (-1,s)S2 are every (s+1)-th upwards antidiagonals of T(s), but with offset m = s instead of m = 0. The proof of the conjecture follows by showing the Carlitz recurrence for (-1,s)S2, but with offset n = 0 and m = 0; that is, a(s; n+1, m+s) =: aHat(s; n, m) = Sum_{j = 0..s} binomial(s, j)*fallfac(s + m - j - (s+1)*n , s-j)*aHat(s; n-1, m-j), for n >= 0, m = 0, 1, ..., s*n, with aHat(s; 0, 0) = 1 and aHat(s; n, m) = 0 for m < 0 and m > s*n. The falling factorials are fallfac(x, n). With aHat(s; n, m) = T(s; (s+1)*n - m, m) this leads to a recurrence for T(s) which is equivalent to the recurrence for the row polynomials RT(s), namely RT(s; n, x) = Sum_{j=0 .. s} binomial(s, j)*x^j*fallfac(s - j - n, s - j)*RT(s; n - (s+1) + j, x), for n >= 1, and RT(s; 0, x) = 1. This, in turn, can be proved by induction over n >= 1 from the simpler recurrence for RT(s) obtained directly from the Rodrigues-type definition, namely RT(s; n, x) = x^s*RT(s; n-1, x) - (d/dx)RT(s; n-1, x), n >= 1,with RT(s; 0, x) = 1.

V3-003172 | OEIS-A091984

Number of steps required for initial p = 10^n to reach 1 in the recurrence p = floor(Li(p)).

The number of steps for the recurrence in this sequence stopping at 1 compares closely to the steps in the pi(n) recurrence stopping at 0. If we define Li(1) = 0 and allow that step then A(using Li seq#) - A(using pi seq#) = 1 for n <=13. So one may conjecture the steps in the Li method is always 1 greater than the steps in the pi method. Question is can the difference be greater than 1? For the largest value allowed in the link (3*10^13) A(Li) = 17 (assuming L1(1)= 0) and n=13 A(pi) = 16 from Booker so the difference = 1 as before.

V3-003180 | OEIS-A092131

Distance from 2^n to the next prime.

Conjecture: Every odd number which is not a Sierpiński number is a term. In other words, for every odd k which is not a Sierpiński number, there exists some n >= 1 such that 2^n + 1, 2^n + 3, ..., 2^n + (k-2) are all composite while 2^n + k is prime. (End)

V3-003181 | OEIS-A092143

Cumulative product of all divisors of 1..n.

Let p be a prime and let ordp(n,p) denote the exponent of the largest power of p which divides n. For example, ordp(48,2) = 4 since 48 = 3*(2^4). Let b(n) = A006218(n) = Sum_{k = 1..n} floor(n/k). The prime factorization of a(n) appears to be given by the following conjectural formula: ordp(a(n),p) = b(floor(n/p)) + b(floor(n/p^2)) + b(floor(n/p^3)) + ... Compare with the comments in A129365. [added 13 May 2026: for a proof of this conjecture by Grok AI see the Bala link.] - _Peter Bala_, Apr 15 2007

V3-003182 | OEIS-A092193

Number of generations for which prime(n) divides A001008(k) for some k.

For any prime p, generation m consists of the numbers p^(m-1) <= k < p^m. The zeroth generation consists of just the number 0. When there is a k in generation m such that p divides A001008(k), then that k may generate solutions in generation m+1. It is conjectured that for all primes there are solutions for only a finite number of generations.

V3-003183 | OEIS-A092210

Positive integers n such that the trajectory of n under the Reverse and Add! operation carried out in base 2 (presumably) does not join the trajectory of any m < n.

The conjecture that the base 2 trajectories of the terms do not join is based on the observation that if the trajectories of two integers < 12000 join, this happens after at most 93 steps, while for any two terms listed above the trajectories do not join within 1000 steps. For pairs from 1, 16, 64, 74, 98, 107 this has even been checked for 5000 steps.

V3-003187 | OEIS-A092287

a(n) = Product_{j=1..n} Product_{k=1..n} gcd(j,k).

Conjecture: Let p be a prime and let ordp(n,p) denote the exponent of the highest power of p that divides n. For example, ordp(48,2)=4, since 48=3*(2^4). Then we conjecture that the prime factorization of a(n) is given by the formula: ordp(a(n),p) = (floor(n/p))^2 + (floor(n/p^2))^2 + (floor(n/p^3))^2 + ... Compare this to the de Polignac-Legendre formula for the prime factorization of n!: ordp(n!,p) = floor(n/p) + floor(n/p^2) + floor(n/p^3) + ... This suggests that a(n) can be considered as generalization of n!. See A129453 for the analog for a(n) of Pascal's triangle. See A129454 for the sequence defined as a triple product of gcd(i,j,k). - _Peter Bala_, Apr 16 2007 The conjecture is correct. - _Charles R Greathouse IV_, Apr 02 2013 Conjecture: For a product over a rectangle, f(n,m) = Product_{j=1..n} Product_{k=1..m} gcd(j,k), a factorization similar to the one given above for the square case takes place: ordp(f(n,m),p) = floor(n/p)*floor(m/p) + floor(n/p^2)*floor(m/p^2) + ... By way of directly computing the values of f(n,m), it can be verified that the conjecture holds at least for all 1 <= m <= n <= 200. - _Andrey Kaydalov_, Mar 11 2019

V3-003204 | OEIS-A092387

a(n) = Fibonacci(2*n+1) + Fibonacci(2*n-1) + 2.

Consider a circle C of radius 5/4 (in some length units) with a chord of length 2. This has been chosen so that the larger sagitta also has length 2. The smaller sagitta has length 1/2. The input, besides the circle C, is the circle C_0 with radius R_0 = 1/4, touching the chord and circle C. The following sequence of circles C_n with radii R_n, n >= 1, is obtained from the conditions that C_n touches (i) the circle C, (ii) the chord and (iii) the circle C_(n-1). The curvature of the n-th circle, C_n = 1/R_n, n >= 0, is conjectured to be a(n). See an illustration given in the link. As found by _Wolfdieter Lang_ (see part II of the proof given by W. Lang in the link), this circle problem is related to the nonnegative solutions of the Pell equation X^2 - 5*Y^2 = 4: a(n) = 2 + X(n) = 2 + A005248(n). For the larger segment below the chord (with sagitta length 2) the sequence would be A115032, see W. Lang's proof given in part I of the link. Conjectures (proved in the next entry) from Colin Barker, Aug 25 2014 (and Aug 27 2014): (Start) The first of the _Colin Barker_ conjectures above is true because of the Binet-de Moivre formula for L(2*n) (see the Jul 24 2003 _Dennis P. Walsh_ comment on A005248). With phi = (1+sqrt(5))/2, use 1/phi = phi-1, phi^2 = phi+1, (phi-1)^2 = 2 - phi. His second conjecture (recurrence) with input a(-3) = 20, a(-2) = 9 and a(-1) = 5 (from the above given recurrence) leads to his g.f. with the expanded denominator. Thus both conjectures are true. (End)

V3-003237 | OEIS-A093387

a(n) = 2^(n-1) - binomial(n, floor(n/2)).

a(2*n+1) = 2*a(2*n) + A000108(n). Together with the first formula by _Emeric Deutsch_, we have a simple system of recursions. Using them, we can prove Mathar's conjecture. For example, let n be odd, n=2*m+1. By the left hand side of Mathar's conjecture, we have (2*m+2)*a(2*m+1) - 2*(2*m+2)*a(2*m) - 4*(2*m-1)*a(2*m-1) + 8(2*m-1)*a(2*m-2) = (2*m+2)*(2*a(2*m) + A000108(m) - 2*a(2*m)) - 4*(2*m-1)*(2*a(2*m-2) + A000108(m-1) - 2*a(2*m-2)) = (2*m+2)*A000108(m) - 4*(2*m-1)*A000108(m-1) = 0, since A000108(m) = binomial(2*m, m)/(m+1). - _Vladimir Shevelev_, Nov 17 2017

V3-003245 | OEIS-A093511

Transform of the prime sequence by the Rule45 cellular automaton.

Conjecture: For n > 3, the a(n) correspond to the following construct (in numerical order). a(n) terms include "bookend" values at every prime p + 1 (6,8,12,14,18,20,...). Additionally, the values between the bookends are included, unless adjacent to non-"twin composite" bookends. For example, consider bookends 6 and 8. There is only a single value 7 between these, so it is included. This means terms 6, 7 and 8 are included. Consider bookends 89 + 1, 97 + 1. Ignoring 91 and 97 adjacencies, values 92 through 96 are included. This means terms 90, 92-96 and 98 are included. - _Bill McEachen_, Jun 12 2024

V3-003309 | OEIS-A094913

Maximal number of distinct nonempty substrings of any binary string of length n.

It would be more natural to include the empty substring, which would result in the sequence b(n)=a(n)+1; all values computed so far confirm the conjecture that a(n)+1 = A006697(n). - _M. F. Hasler_, Dec 17 2007 Calculations suggest that, for any n>0, binary strings of length n exist such that the number of distinct substrings of length k, 1<=k<=n, is as large as possible consistent with basic counting principles, i.e., n-k+1 substrings of length k starting at each of the n-k+1 possible starting positions, subject to the condition, however, that there cannot be more than 2^k distinct binary strings of length k. This suggests the following conjecture. Conjecture: The maximum number a(n) of distinct substrings of a binary string of length n is given by a(n) = Sum_{k=1..n} t(k) where t(k) is the smaller of 2^k and n-k+1. Conjecture: a(n) = A006697(n)-1. - _Vladeta Jovovic_, Sep 19 2005 Conjecture: a(n) = 2^(m+1)-2 + (n-m)(n-m+1)/2, where m = floor(n+1-LambertW(2^(n+1) * log(2)) / log(2)) = integer part of the solution to 2^x = n+1-x. This is based on the reasoning that you can construct the word of length n so that it contains the maximal possible number, max(n-k+1, 2^k), of different substrings of length k. - _M. F. Hasler_, Dec 17 2007 Conjecture: column sums of:

V3-003356 | OEIS-A096270

Fixed point of the morphism 0->01, 1->011.

Conjecture: a(n) is given recursively by a(1)=0 and, for n>1, by a(n)=1 if n=F(2k+1) and a(n)=a(n-F(2k+1)) otherwise, where F(2k+1) is the largest odd-indexed Fibonacci number smaller than or equal to n. (This has been confirmed for more than nine million terms.) The odd-indexed bisection of the Fibonacci numbers (A001519) is {1, 2, 5, 13, 34, 89, ...}. So by the conjecture, we would expect that a(30) = a(30-13) = a(17) = a(17-13) = a(4) = a(4-2) = a(2) = 1, which is in fact correct. - _John W. Layman_, Jun 29 2004 Proof of the above conjecture: Let g be the morphism above: g(0)=01, g(1)=011. Then g^n(0) has length F(2n+1), and (a(n)) starts with g^n(0) for all n>0. Obviously g^n(0) ends in 1 for all n, proving the first part of the conjecture. Since v(n) has length F(2n-1), which is the largest odd-indexed Fibonacci number smaller than or equal to m for all m between F(2n-1) and F(2n+1), the claim proves the second part of the conjecture. (End)

V3-003401 | OEIS-A097602

a(n+1) = a(n) + number of squares so far; a(1) = 1.

Conjecture: a(n) = m^2 iff m mod 3 > 0.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Reinhard Zumkeller_, Aug 30 2004 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003402 | OEIS-A097702

a(n) = (A063880(n) - 108)/216.

Conjecture: k is a term iff 6*k+3 is squarefree. - _Vladeta Jovovic_, Aug 27 2004 It is only a conjecture that all terms are integers (confirmed up to 10^6 by _Robert G. Wilson v_). The first conjecture is true. If m = 216*k + 108 = 108 * (2*k + 1) is a term of A063880, then 2*k+1 is a squarefree number coprime to 6. This is because sigma(n)/usigma(n) is multiplicative, equals 1 if and only if n is squarefree and larger than 1 otherwise, sigma(108)/usigma(108) = 2 and sigma(3^k)/usigma(3^k) increases with k. 6*k+3 = 3*(2*k+1) is squarefree because 2*k+1 is a squarefree coprime to 6.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Ralf Stephan_, Aug 26 2004 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003403 | OEIS-A097703

Numbers j such that m = 216*j + 108 satisfies sigma(m) != 2*usigma(m).

Conjecture: all numbers of form 3k + 1 are here. Other terms are listed in A097704. The conjecture is true. If j = 3*k+1, then m = 324*(2*k+1). Let e = A007949(2*k+1) >= 0, so 2*k+1 = 3^e * i and i coprime to 6. Then sigma(m)/(2 * usigma(m)) = (7/20) * (3^(e+5)-1)/(3^(e+4)+1) * sigma(i)/usigma(i) >= 847/820 > 1, because sigma(i)/usigma(i) >= 1 for all i.

V3-003411 | OEIS-A097945

a(n) = mu(n)*phi(n) where mu(n) is the Mobius function (A008683) and phi(n) is the Euler totient function (A000010).

Conjecture: Sum_{n>=1} mu(n)/phi(n) = Sum_{n>=1} a(n)/phi(n)^2 = 0. It is true that Sum_{n>=1} mu(n)/phi(n)^s = 0 at least for s > 1 since: phi(2)=1, phi is multiplicative, so for n's that are squarefree, the phi(n) values can be partitioned in pairs where phi(m)=phi(2m) and mu(m) = -mu(2m). So Sum_{i=1..n} mu(i)/phi(i)^s < Sum_{j=floor(n/2)..n} 1/phi(j)^s, which approaches 0 as n increases since (1) n^(1-e) < phi(n) < n for any e > 0 and n > N(e) and (2) Sum_{i..n} 1/n^s converges for s > 1. Conjecture: Sum_{n>=1} mu(n)/phi(n)^z = 0 for Re(z) > 1.

V3-003432 | OEIS-A098550

The Yellowstone permutation: a(n) = n if n <= 3, otherwise the smallest number not occurring earlier having at least one common factor with a(n-2), but none with a(n-1).

Conjectures: 7. Based on the first 250000 terms, I conjectured on Nov 30 2014 that a(n)/n <= (Pi/2)*log n. 8. The primes in the sequence appear in their natural order.

This conjecture is very plausible but as yet there is no proof. - _N. J. A. Sloane_, Jan 29 2015

V3-003444 | OEIS-A099120

Least m such that n = S(k) = S(k+m) for some k, where S is the Kempner function A002034.

Consider the set Sn of d(n!)-d((n-1)!) positive integers k with S(k) = n, where d is the divisor counting function A000005. For each n, a(n) gives the least difference of integers in the set Sn. For prime n, a(n) = n. For n a power of a prime, a(n) = A046021(n), the least k in Sn. The Tutescu conjecture, which states that the equation S(k) = S(k+1) has no solutions, is equivalent to a(n) > 1 for all n.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _T. D. Noe_, Sep 28 2004 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003445 | OEIS-A099143

Least k such that S(k) = S(k+n), or 0 if there is no k, where S is the Kempner function A002034.

The case of n=1 corresponds to the Tutescu conjecture, which states that the equation S(k) = S(k+1) has no solutions. It is conjectured that S(k) = S(k+6) also has no solutions. For odd prime p, a(p) = p. It appears that a(n) <= n, except for n = 1, 2, 6, 24, 48, 120, 240, 720 (A099144).

V3-003505 | OEIS-A101349

Numbers of cubes between prime(n) and prime(n+1).

a(n) <= 1 for all n if and only if there is a prime between k^3 and (k+1)^3 for every k >= 1, which is an open conjecture. It has been verified by computation for k^3 <= 1.649*10^40 (Johnston, Sorenson, Thomas and Webster), so a(n) <= 1 whenever prime(n+1) <= 1.6*10^40; analytically it is known only for k >= exp(exp(32.537)) (Cully-Hugill). - _Pierre Colmant_, Oct 19 2026

V3-003540 | OEIS-A102612

First nonzero terms in the sequences formed by the unique count of primes between an and (a+1)n.

Care should be taken to choose a sufficiently large n for a given m range for a in the script below. (50,1000) -> 22,11,18,62,59,29,12,47,106,40,17,104,94,44,83,22,.. (50,2000) -> 22,11,18,62,59,29,12,47,106,40,17,104,94,44,83,180,.. Notice the breakdown at the end. While the terms in the sequence tend to oscillate increasing, strange things are possible when more terms are listed. Conjecture: The number of terms in this sequence is infinite.

V3-003546 | OEIS-A102842

Insipid numbers: n is defined to be insipid if "G is a primitive subgroup of the symmetric group S_n" implies that "G=A_n or G=S_n".

It seems hard to find long gaps in this sequence. It seems plausible (this is implied by some conjectures in number theory) that there are infinitely many strings of 5 consecutive positive integers not in this sequence; however, I do not know of a construction which should yield infinitely many strings of 6 consecutive positive integers which are in the sequence (this may be just a reflection of my ignorance of the right families of finite groups); the largest example I know of a string of more than 5 consecutive integers not in this sequence has length 7 and first term 2^150-5.

V3-003580 | OEIS-A103828

Sequence of odd numbers defined recursively by: a(1)=1 and a(n) is the first odd number greater than a(n-1) such that a(n) + a(i) + 1 is prime for 1<=i<=n-1.

The Hardy-Littlewood k-tuple conjecture would imply that this sequence is infinite. Note that, for n>2, a(n)+2 and a(n)+4 are both primes, so a proof that this sequence is infinite would also show that there are infinitely many twin primes. - _N. J. A. Sloane_, Apr 21 2007

V3-003591 | OEIS-A104109

Numbers n such that whenever a group G has a solvable subgroup of index n, then G itself is solvable.

As for the primes in the sequence, a theorem proved by Burnside guarantees that any unsolvable permutation group on a prime number of points is doubly transitive. The classification of doubly transitive permutation groups has been completed and it can be used to show that the only primes not in this sequence are 7, 13 and the Fermat primes larger than 3. So assuming the standard conjecture that 65537 is the largest Fermat prime, all primes except for these six (5, 7, 13, 17, 257 and 65537) are in this sequence.

V3-003650 | OEIS-A106521

Numbers m such that Sum_{k=0..10} (m+k)^2 is a square.

11*((m+5)^2+10) is a square iff the second factor is divisible by 11 and the quotient is a square, i.e., iff m = 11*k - 4 or m = 11*k - 6 and 11*k^2 +- 2 k + 1 is a square. Thus a(n) == (7,5,5,7,7,5,5,7,...) (mod 11), repeating with period 4 and the values are obtained by solving these Pell-type equations (cf. link to Dario Alpern's quadratic solver). The corresponding recurrence equations (see PARI code) should make it possible to prove the conjectured g.f. - _M. F. Hasler_, Jan 27 2008

V3-003691 | OEIS-A108411

a(n) = 3^floor(n/2). Powers of 3 repeated.

Conjecture: a(n+1) is the number of distinct subsets S of {0,1,2,...,n} such that the sumset S+S does not contain n. - _Michael Chu_, Oct 05 2021. _Andrew Howroyd_, Nov 20 2021: The conjecture is true: If there are m pairs of numbers that add to n then inclusion/exclusion gives sum(k=0, m, binomial(m,k)*(-1)^k*2^(2*m-2*k)) as the number of sets that don't contain any of those pairs which equals 3^m. For even n , n/2 cannot be included in any set.

V3-003698 | OEIS-A108625

Square array, read by antidiagonals, where row n equals the crystal ball sequence for the A_n lattice.

Conjectural result for superdiagonals: zeta(2) = 1 + 1/2^2 + ... + 1/k^2 + Sum_{n >= 1} (-1)^(n+1) * (5*n^2 + 6*k*n + 2*k^2)/(n^2*(n+k)^2*T(n-1,n+k-1)*T(n,n+k)), k = 0,1,2... . Conjectural result for subdiagonals: zeta(2) = 2*(1 - 1/2^2 + ... + (-1)^(k+1)/k^2) + (-1)^k*Sum_{n >= 1} (-1)^(n+1)*(5*n^2 + 4*k*n + k^2)/(n^2*(n+k)^2*T(n+k-1,n-1)*T(n+k,n)), k = 0,1,2... . Conjectural congruences: the main superdiagonal numbers S(n) := T(n,n+1) appear to satisfy the supercongruences

S(m*p^r - 1) = S(m*p^(r-1) - 1) (mod p^(3*r)) for all primes p >= 5 and all positive integers m and r. If p is prime of the form 4*n + 1 we can write p = a^2 + b^2 with a an odd number. Then calculation suggests the congruence S((p-1)/2) == 2*a^2 (mod p). (End) Conjecture: for positive integer m, Sum_{k = 0..n} (-1)^(n+k) * binomial(n, k) * T(m*n, k) = ((m+1)*n)!/(((m-1)*n)!*n!^2) (verified up to m = 10 using the MulZeil procedure in Doron Zeilberger's MultiZeilberger package). (End)

V3-003724 | OEIS-A109326

Smallest positive number that requires n steps to be represented as a sum of palindromes using the greedy algorithm.

The greedy algorithm means iteration of A261424 until a palindrome is reached. For n = 3, 4, ... we have a(n+1) = 10^L(n) + a(n) + 1 with L(n) = 2^(n-2) + 1 = length(a(n))*2 - 3 for n > 3. We have a(7) <= 10^17 + 1000101025, a(8) <= 10^33 + 10^17 + 1000101026, a(9) <= 10^65 + 10^33 + 10^17 + 1000101027, a(10) <= 10^129 + 10^65 + 10^33 + 10^17 + 1000101028, etc, with conjectured equality. - _M. F. Hasler_, Sep 08 2015, edited Sep 09 2018 a(n) = Sum_{0 <= k <= n-3} 10^(2^k+1) + n - 82, for n > 2 (conjectured). - _M. F. Hasler_, Sep 08 2015

V3-003766 | OEIS-A110312

Minimum number of polygonal pieces in a dissection of a regular n-gon into a square (conjectured).

Minimum number of polygonal pieces in a dissection of a regular n-gon into a square (conjectured). The three related sequences A110312, A362938, A362939 are exceptions to the usual OEIS policy of requiring that all terms in sequences must be known exactly. These sequences are included because of their importance and in the hope that someone will establish the truth of some of the conjectured values.

V3-003770 | OEIS-A110358

Beginning with 3, the least prime which is the product of one or more previous terms + 2.

Conjecture: The sequence is infinite. Subbarao & Yip prove that if there is an integer m such that the equation Phi_2(x) = m has a unique solution, where Phi_2 is the 2nd Schemmel totient function (A058026), then x == 0 (mod a(n)^2) for each term in this sequence. They conjectured an analog to Carmichael's conjecture, that this equation has no unique solution to any integer m, and prove that any counterexample to this conjecture is > 10^120000, a bound calculated from the first 10000 terms of this sequence. A proof that this sequence is infinite would prove the conjecture. - _Amiram Eldar_, Mar 25 2017

V3-003807 | OEIS-A111166

Let p < q be consecutive primes; p is in the sequence if p/(q-p) is a record.

Conjecture: Except for first term, the sequence coincides with A001359. This is true for all primes < 2*10^7. Conjecture: Except for first term, the sequence coincides with A001359. This is true for all primes < 7*10^16. Let n >= 2 be an integer, N +- 1 and M +- 1 two consecutive twin pairs where M>n*N. Finding a counterexample is the same as finding two consecutive primes P1 and P2 with n*N<P1<M and P2-P1 <= n. However, such gaps are unknown even for n=2.

V3-003808 | OEIS-A111184

Triangle T(n,k), 0<=k<=n, read by rows, given by [0, 2, 1, 3, 2, 4, 3, 5, 4, 6, 5, 7, 6, ...] DELTA [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...] where DELTA is the operator defined in A084938.

Conjecture 1: Sum_{k=1..n} T(n,k)*q^(k-1) = A111528(q,n) for n > 0, q >= 0. Conjecture 2: Sum_{k=1..n} T(n,k)*(-1/q)^(k-1) = R(n,q)/q^(n-1) for n > 0, q > 0 where log(1 + x + q*x*[Sum_{k>=1} R(k,q)*x^k]) = Sum_{k>=1} R(k,q)/k*x^k. Conjecture 3: n-th row polynomial is x*v_n for n > 0 where we start with vector v of fixed length m with elements v_i = 1, and for i=1..m-1, j=i+1..m apply A := v_i (at the beginning of each cycle for i) and also apply A := A + v_j, v_j := (j-i+x-1)*v_j + A. Here last conjecture provides fast and simple algorithm, that allow to compute sums in the previous conjectures by substituting x = q and x = -1/q respectively. (End)

V3-003822 | OEIS-A111802

a(n) = n^2 - n - 1 for n>3; a(1)=1; a(2)=2; a(3)=3.

Inspired by attempt to determine what incorrectly-named A000519 may really be. Conjecture: Sequence is number of different main-diagonal sums among Latin squares of order n. Confirmed for first five terms. Guaranteed to be an upper bound as the diagonal sum can only be in the range from n to n^2 inclusive and it is impossible for the sum to be n+1 or n^2-1. There is probably an easy proof that all other sums in this interval can be realized as the only restriction seems to be that it is not permissible for exactly n-1 numbers on a diagonal to be identical.

V3-003845 | OEIS-A112725

Smallest positive palindromic multiple of 3^n.

a(0)=1; a(1)=3 and it is easily shown that for n>1, 10^3^(n-2)-1 is a palindromic multiple of 3^n(see comments line of A062567). So for each n, a(n) exists and for n>1, a(n)<=10^3^(n-2)-1. This sequence is a subsequence of A020485(a(n)=A020485(3^n)) and for all n, A062567(3^n)<=a(n) because for all n, A062567(n)<=A020485(n). Jud McCranie conjectures that for n>1 A062567(3^n) =10^3^(n-2)-1, if his conjecture were true then from the above facts we conclude that for n>1 a(n)=10^3^(n-2)-1, but we see that for 4<n<=18 a(n) is much smaller than 10^3^(n-2)-1, so his conjecture will be rejected.

V3-003846 | OEIS-A112726

First positive multiple of 3^n whose reverse is also a multiple of 3^n.

a(0)=1; a(1)=3 and it is easily shown that for n>1, 10^3^(n-2)-1 is a multiple of 3^n whose reverse is also a multiple of 3^n (see comments line of A062567), so for each n, a(n) exists and for n>1, a(n)<=10^3^(n-2)-1. This sequence is a subsequence of A062567, a(n)=A062567(3^n). Jud McCranie conjectures that for n>1, a(n)=10^3^(n-2)-1 (see comments line of A062567), but we see that for n>4, a(n) is much smaller than 10^3^(n-2)-1, so his conjecture is rejected. It seems that only for n=2,3 & 4 we have, a(n)=10^3^(n-2)-1.

V3-003847 | OEIS-A112730

Numbers k such that the equation sigma(x)-phi(x)=k has at least one solution.

It is conjectured that if n>2 then all solutions of the equation sigma(x)-phi(x)=n (*) are less than or equal to (n-1)^2/4 and 2 is the only number n such that the equation (*) has infinitely many solutions. In fact in the case n=2 prime numbers are all solutions of (*). All numbers of the form

2p+1 where p is prime are in the sequence because p^2 is a solution for the equation sigma(x)-phi(x)=2p+1. All numbers of the form 3*2^n-1 are in the sequence because 2^(n+1) is a solution for the equation sigma(x)-phi(x)=3*2^n-1 and etc. The conjecture in the previous comment was established by Luke Pebody, see the Rivera link.

V3-003883 | OEIS-A113598

Least n-digit prime whose digit permutations yield at least n distinct primes, or 0 if no such prime exists.

Conjecture: No term is zero.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Amarnath Murthy_, Nov 07 2005 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003884 | OEIS-A113599

Least n-digit multiple of n whose digit permutations yield at least n distinct multiples of n, or 0 if no such number exists.

Conjecture: No term is zero. The proof should be simple. The conjecture is true: There are 9*10^(n-1) n-digit numbers, meaning at least floor(9*10^(n-1)/n) n-digit multiples of n. There are binomial(n+9, 9) multisets of n digits. Thus, by the pigeonhole principle, one of these multisets contains at least ceiling(floor(9*10^(n-1)/n)/binomial(n+9, 9)) multiples of n, and this number is at least n whenever n > 3. - _James Rayman_, Feb 14 2023

V3-003890 | OEIS-A113755

Sequence implicit in Jaroma's corollary to Nagura's theorem on primes.

Tightening the bounds on J. Bertrand's 1845 conjecture that for any integer n > 3 there exists at least one prime between n and 2*n-2 (proved by P. Tchebechev in 1852), Nagura proved that, for n >= 25, there exists at least one prime number between n and (6/5)*n. John H. Jaroma gives an elementary proof by induction of the corollary: prime(n) < (1.2)^n for n > 25. Equivalently, this sequence, implicit in Nagura and Jaroma, is always positive after a(25). The minimum is reached with min((1.2)^n - prime(n)) = (1.2)^17 - 59 = -36.8138889.

V3-003898 | OEIS-A114021

Number of semiprimes between n and n + sqrt(n).

It appears that for n > 37 it is always true that a(n) > 0. The exponent can be reduced further. Since 597 + 597^(0.4129) > 611, leaping the record semiprime gap between 597 and 611, it seems that for n > 597 it is always true that there is a semiprime between n and n^(0.4129). It seems that for n > 2705 it is always true that there is a semiprime between n and n^(0.3509). These conjectures are related to the various sequences about semiprime gaps and the merit of such gaps.

V3-003900 | OEIS-A114112

a(1)=1, a(2)=2; thereafter a(n) = n+1 if n odd, n-1 if n even.

The induction hypotheses are: for i<n, a(2i)=2i+1, a(2i)=2i-1, A(2i)=i(2i+1), A(2i) = 2i^2+3i+2. This implies that when looking for a(2i), we have seen all the numbers 1 through 2i except 2i-1, so the two smallest candidates for a(2i) are 2i-1 and 2i+1. Since 2i-1 does not divide 2i^2-i-1, a(n)=2i-1. When looking for a(2i+1), we have seen all the numbers 1 through 2i already, so the two smallest candidates for a(2i+1) are 2i+1 and 2i+2. But 2i+1 does divide A(2i) and 2i+2 does not, so a(2i+1)=2i+2. QED The g.f. for the b(n) sequence is x*(x^3-3*x^2+2*x+2)/((1-x)*(1-x^2)). - Conjectured (correctly) by _Colin Barker_, Mar 04 2018

V3-003907 | OEIS-A114381

Sums of p-th to the q-th prime where p and q are consecutive primes.

The number of terms in this sequence is infinite since there is no largest prime number. Conjecture: There will always be an n and i such that a(n) >= a(n+i) or the sequence will alternate forever. Equality does take place in the small sample shown with the entry 991. Certainly the proof of an infinity many twin primes would be a strong probable proof of this assertion. My guess is the alternation would always occur when a twin prime is encountered and often for other consecutive primes such as those differing by 4.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003925 | OEIS-A114976

Number of subsets of {1,2,....,n} with an arithmetic mean that is an integer and also a divisor of n.

a(n) = 2 iff n is prime, just as for the number of divisors of n and also, at least for the very first terms, a(n)=odd iff n is a square: these observations might suggest conjectures on a deeper relationship with A000005.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Reinhard Zumkeller_, Feb 22 2006 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003926 | OEIS-A115016

a(n) is the smallest number k that has a shortest addition chain whose length A003313(k) = A003313(n*k), or 0 if this never happens.

It was conjectured that no shortest addition chains exist such that A003313(m)=A003313(m*2^k) for k>1. This is now known to be false, since a(4) != 0.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Hugo Pfoertner_, Feb 26 2006 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003927 | OEIS-A115038

a(n) is the smallest x such that x^2 + prime(n) is a perfect power.

Conjecture: There will always be an x,y,n such that x^2 + p = y^n for all primes p. In otherwords, there is a one-one mapping of the prime numbers to y^n - x^2 for some x,y,n. Therefore primes of the form y^n - x^2 are infinite in number.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Cino Hilliard_, Feb 26 2006 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003928 | OEIS-A115047

a(3)=1; a(n) = Sum_{i=1..n-3} binomial(n-4,i-1)*binomial(n,i+1)*a(i+2)*a(n-i)*i*(n-i-2)/(2*(n-1)) for n > 3.

I conjecture that a(n) is divisible by n if n is a prime. - _Michael Somos_, Sep 20 2014

V3-003975 | OEIS-A117215

Number of divisors of x^n-1 having the maximal height A114536(n).

Let p be a prime. Then a(p)=4 because the divisors are x^p-1, x^(p-1)+x^(p-2)+...+1, x-1 and 1. Similarly, a(p^k)=2^(k+1). For n=p*2^k, a(n)=2. For odd primes p

and q, a(pq)=1. Conjectures: if n is odd and squarefree, then a(n)=1; if n/2^k is odd and squarefree for k>0, then a(n)=2. All the divisors of x^n-1 are products of cyclotomic polynomials cyclo(d) for various d. When n is the product of distinct odd primes p1..pk, it appears that each cyclotomic index has the form d=p1^e1...pk^ek, where the ei are either 0 or 1 and sum(ei) is odd.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-003989 | OEIS-A117846

Given n, define a(n) as follows: let a sequence b(k) be defined by b(k+1)=b(k)+b(k)mod k; b(1)=2n-1. (Here b(k)mod k denotes the least nonnegative residue of b(k) modulo k). Let a(n) be the common value of b(k+1)-b(k) for all large k if such exists; otherwise let a(n) be 0.

Putting b(1)=2n gives essentially the same sequence as putting b(1)=2n-1. It is a plausible conjecture or at least an interesting open problem that a(n) is never zero; that is all the sequences b(k) are arithmetic progressions from some point on. Sequence A073117 is the sequence b(k) with b(1)=1. Do the values a(n) include all positive numbers?

V3-003993 | OEIS-A117969

Start of least run of maximal length of consecutive n-almost primes.

For n>=2 there cannot be more than 2^n - 1 consecutive n-almost primes. Is it known whether there always exists such a run of length 2^n - 1? If not, I conjecture so. This is confirmed to be true for terms through a(4). Terms here equal the last terms of corresponding finite sequences: a(3) = A067813(6). a(4) was computed by _Don Reble_ as A067814(14). a(5) >= A067820(12).

V3-004051 | OEIS-A119690

a(n) = n! mod n*(n+1)/2.

Layman's conjecture above is true for every k >= 0. Proof: if n+1 is not an odd prime, then n(n+1)/2 divides n! (see A069268), so every positive power of n! is 0 modulo n(n+1)/2. If n+1 = p is an odd prime, write n(n+1)/2 = h*p with h = n/2, gcd(h,p) = 1. Then n! == 0 (mod h), and n! == -1 (mod p) by Wilson's theorem, so for odd j, (n!)^j == 0 (mod h) and == -1 (mod p). Since n = 2h == 0 (mod h) and n = p-1 == -1 (mod p), the Chinese remainder theorem gives (n!)^j == n (mod n(n+1)/2), and 0 <= n < n(n+1)/2. - _Scott M. Foltz_, Sep 24 2026

V3-004061 | OEIS-A120160

a(n) = ceiling(Sum_{i=1..n-1} a(i)/4) for n >= 2 starting with a(1) = 1.

Conjecture 1: a(n) equals the number of multiples of 4 whose representation in base 5/4 (see A024634) has n-1 digits. For example, a(8) = 3 because there are three multiples of 4 with n-1 = 7 digits in their representation in base 5/4: 36 = 4321031, 40 = 4321420, and 44 = 4321424. Conjecture 2: a(n) equals 1/5 times the number of nonnegative integers with the property that their 5/4-expansion has n digits (assuming that the 5/4-expansion of 0 has 1 digit). For example, a(7)*5 = 10 because the following 10 numbers have 5/4 expansions with n = 7 digits: 35 = 4321030, 36 = 4321031, 37 = 4321032, 38 = 4321033, 39 = 4321034, 40 = 4321420, 41 = 4321421, 42 = 4321422, 43 = 4321423, and 44 = 4321424. (End) Starting at a(11) = 5, we conjecture that this sequence gives all those numbers m for which when we place m persons on a circle, label them 1 through m, start counting at person number 1, and remove every 5th person, the last survivors have numbers in {1, 2, 3, 4}.

V3-004072 | OEIS-A120451

Number of ways a prime number p can be expressed as 2*(p1-p2) + 3*p3, where p1, p2, p3 are primes or 1, less than or equal to p.

At least for the first 200 primes, it is true that every prime p > 2 can be expressed as 2*(p1-p2) + 3*p3, where p1, p2, p3 are primes or 1, less than or equal to p (the proof would be straightforward if both (a) Levy's conjecture and (b) the conjecture saying that every prime p > 3 can be expressed as 2*p1 + 3*p2, where p1, p2 are primes, were true). It would be interesting to study how the sequence changes when we remove the restriction for p1, p2, p3 to be less than or equal to p.

V3-004076 | OEIS-A120643

Table T(n,k) = number of fractal initial sequences (where new values are successive integers) of length n whose last term is k.

A fractal sequence is one where, when the first instance of each integer is removed, the original sequence results. We require also that these first instances occur in order: 1,1,2,3 is OK, but 1,1,3,2 is not. A finite sequence is an initial subsequence of (uncountably many) fractal sequences when the result after removing the first instance of each number is an initial subsequence. The total number of such sequences of length n is 2^{n-1}. At each index after the first, the next value can be either a new value or a uniquely determined repetition of some earlier value. Conjecture: column 1 of this array is A007059.

V3-004080 | OEIS-A120811

Positive integers n such that n+d+1 is prime for all proper divisors d of n. Generalization of twin prime to all integers.

This sequence (A120811) is a generalization of twin prime (A001359), the sequence A120776 is a generalization of Sophie Germain prime (A005384), while A120806 is the generalization of Sophie Germain twin prime (A045536). The same observations apply to A120811 as to A120806: the elements are (a) twin primes, (b) semiprimes pq, (c) 3-almost-primes, (d) 4-almost-primes. Moreover, the sequence includes all twin primes but in (b), (c) and (d) the containments are proper. The first occurrence of (d) is A120811(3980)=3^3*13147. Any others? A120811 CONJECTURE: These are all the elements, that is, no element of A120811 has more than 3 prime factors with no degree (sum of exponents) higher than 4.

V3-004103 | OEIS-A121510

Conjectured to be complete list of cycle lengths for 3x+1 (or Collatz) problem.

Conjectured to be complete list of cycle lengths for 3x+1 (or Collatz) problem. The sequence counts cycles over the domain of all integer values: (0), (-1, -2), (4, 2, 1), (-5, -14, -7, -20, -10), and (-17, -50, -25, -74, -37, -110, -55, -164, -82, -41, -122, -61, -182, -91, -272, -136, -68, -34); the generalized cycle conjecture asserts that these are the only such cycles (see Kaneda link). - _Michael S. Branicky_, Nov 10 2025

V3-004108 | OEIS-A121627

Real part of a complex operation analogous to the factorials.

Conjecture (1): Current nonzero term divides next nonzero term; as an operation, getting a new sequence: 12, 8, 5, 84, 16, 9, 220, 24, 13, ...; using unsigned terms). Example: a(5) = -480 and a(7)= 40320, the next nonzero term in the sequence. Then 40320/480 = 84. Conjecture (2): If the term in (12, 8, 5, ...) is generated from a(n)/a(n-1) or a(n)/a(n-2), then n divides each (12, 8, 5, ...). Example: a(11) = -1277337600 and the previous nonzero term = a(9) = 5806080. Then a(11)/a(9) = 220 and 11 divides 220: 220/11 = 20. Due to the statements (1) and (2) below a(n) divides a(n+k) for all k>=0, only provided both the residues of n (mod 8) and (n+k) (mod 8) are 0, 1, 3, 4, 5 or 7. As a consequence it follows that conjecture (1) plainly holds true (set k=1). From statements (1) and (2) it further follows that n! divides a(n) (for n with a(n)<>0) and therefore conjecture(2) also holds true.
