V3-008636 | OEIS-A238576

Number of odd primes p < 2*n with prime(n*(p-1)/2)^2 - 2 prime.

Conjecture: (i) a(n) > 0 for all n > 1, and a(n) = 1 only for n = 2, 7, 23, 61, 73. Clearly, either part of the conjecture implies that there are infinitely many primes of the form p^2 - 2 with p prime.

V3-008688 | OEIS-A239352

van Heijst's upper bound on the number of squares inscribed by a real algebraic curve in R^2 of degree n, if the number is finite.

In 1911 Toeplitz conjectured the Square Peg (or Inscribed Square) Problem: Every continuous simple closed curve in the plane contains 4 points that are the vertices of a square. The conjecture is still open. Many special cases have been proved; see Matschke's beautiful 2014 survey. Recently van Heijst proved that any real algebraic curve in R^2 of degree d inscribes either at most (d^4 - 5d^2 + 4d)/4 or infinitely many squares. He conjectured that a generic complex algebraic plane curve inscribes exactly (d^4 - 5d^2 + 4d)/4 squares.

V3-008723 | OEIS-A240114

Maximal number of points that can be placed on a triangular grid of side n so that no three of them are vertices of an equilateral triangle in any orientation.

Conjecture: for n >= 11, a(n) = 3n-11. (End) The conjecture a(n) = 3*n - 11 (for n >= 11) is false; a(n) grows superlinearly. In triangular-lattice coordinates, a set with no equilateral triangle contains no triple (x,y), (x+r,y), (x,y+r) with r > 0 (these three points are mutually equidistant), so it is corner-free; hence a(n) = o(n^2) by the corners theorem of Ajtai and Szemeredi. Conversely a(n) >> n^(log_7(12)) = n^(1.2769...) by an explicit triangular-lattice construction (Polansky 2019). Hence a(n)/n -> infinity. - _Josh Arnold_, May 30 2026

V3-008725 | OEIS-A240136

Prime numbers in the Antikythera mechanism.

The Antikythera Mechanism is a unique Greek geared device, constructed around the end of the 2nd Century B.C. This device is a sophisticated arrangement of bronze gears, which can calculate the relative positions of the Sun and Moon, lunar phases and even eclipses. It is conjectured that it could also calculate the positions of the inner planets, but this is unproven. It was recovered from a Roman shipwreck in 1900 as a corroded mass of gear work. Detailed analysis could only really begin once X-ray equipment became available. Scans performed over the last 20 years have added significant clues as to the function and operation of the device. Ratios of gear tooth counts in the device indicate a good match to ratios used by the ancients to calculate the dates of eclipses using the Saros and Metonic cycles. Fragments of text recovered from the device mention the sun and moon and use month names used by the Greek city of Corinth and its colonies.

V3-008747 | OEIS-A240775

The six values n in each interval [i*840, (i+1)*840), where i >= 0, for which Mordell's formulas do NOT provide a three-Egyptian-fraction solution for 4/n.

Erdős and Straus conjectured that for all integers n >= 2, the rational number 4/n can be expressed as an Egyptian fraction with exactly three unit fractions -- that is, 4/n = 1/x + 1/y + 1/z where x, y and z are positive integers. The conjecture has been verified to high values of n, and Mordell has provided formulas to compute x, y and z for many n. The values of n NOT included in Mordell's formulas are those for which n modulo 840 = {an element of this sequence}. Each element is the square of a prime.

V3-008782 | OEIS-A241605

a(n) = |{0 < k < sqrt(prime(n))*log(prime(n)) : k is not only a quadratic nonresidue modulo prime(n) but also a Fibonacci number}|.

Conjecture: For any odd prime p, let f(p) be the least Fibonacci number which is a quadratic nonresidue modulo p. Then f(p) = o(p^(0.7)) as p tends to infinity. Moreover,f(p) = O(p^c) for any constant c > c_0 = log_2((1+sqrt(5))/2). This refinement of the conjecture in A241568 seems reasonable in view of the heuristic arguments described below. Let c be any constant greater than c_0 (which has the approximating value 0.694). Roughly speaking, there are about (log_2(p^c))/c_0 positive Fibonacci numbers below p^c. Suppose that a positive Fibonacci number is a quadratic residue modulo a fixed odd prime p with "probability" 1/2. Then we might expect that the "probability" for all positive Fibonacci numbers below p^c being quadratic residues modulo p is about (1/2)^(c*(log_2 p)/c_0) = 1/p^(c/c_0). As sum_p 1/p^(c/c_0) converges, it seems reasonabale to think that there are only finitely many odd primes p for which all positive Fibonacci numbers below p^c are quadratic residues mod p.

V3-008805 | OEIS-A242030

Irregular triangle read by rows of a variation of the Collatz iteration with signature (1,1).

It is conjectured that the trajectory of this Collatz-like iteration arrives at 8 in a finite number of steps for any initial value x, (x>2). The iterative step is divide by 2 and add 1 if even, or multiply by 3 and subtract 1 if odd. Two variations belong to the same subset if their (a) parameters are the same and their (b) parameters have the same parity. It is

conjectured that any variations belonging to the same subset have equal row lengths.

V3-008847 | OEIS-A242462

a(1) = 10; for n>1, a(n) = (a(n-1)-1) * (smallest odd prime factor of a(n-1)) + 1.

Conjecture: this sequence is infinite (so it contains no powers of 2). The similarly defined sequence starting with a(1) = 6 terminates after 2 terms: 6 and 16. Conjecture is true if it turns out that one number in this sequence is one more than a multiple of 41. Any number of the form 2^n-1 that is divisible by 41 is also divisible by 25, which is the square of a prime number greater than 3. Because numbers one less than this sequence's terms are always 9 times a squarefree number, this proves that if a number one less than this sequence is divisible by 41, then this sequence is infinite. - _J. Lowell_, Jul 17 2017 Conjecture is also true if it turns out that one number in this sequence is a multiple of either 19 or 73. Any number of the form 2^n-1 that is divisible by 19 is divisible by 27, and any number of the form 2^n-1 that is divisible by both 73 and 9 is divisible by 27. Numbers one less than this sequence are always divisible by 9 but not by 27. - _J. Lowell_, Feb 27 2022

V3-008876 | OEIS-A242922

Least number k such that (k^n+n^k)/(k+n) is prime or 0 if no such k exists.

a(n) = 0 is definite for n=1. For other n-values where a(n) = 0, it is confirmed for k <= 5000. These are only conjectural.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Derek Orr_, May 26 2014 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008877 | OEIS-A242928

Least number k such that (k^k+n^n)/(k+n) is prime or 0 if no such k exists.

a(n) = 0 is confirmed for k <= 2500. These are just conjectural.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Derek Orr_, May 26 2014 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008878 | OEIS-A242932

Numbers n such that k*n/(k+n) is prime for some k.

A number n belongs to this sequence iff n belongs to the set {p+1, 2*p, p*(p+1)}, for some prime p. In particular, the conjecture regarding A016742 is true (see Fried link). - _Sela Fried_, Mar 27 2026

V3-008880 | OEIS-A242970

Decimal expansion of the constant rho = lim f(n)^(1/n), where f(n) = A214833(n) is the number of arithmetic formulas for n (cf. comments).

This is the constant rho, given on page 2 of E. K. Gnang and others. From the abstract: "An arithmetic formula is an expression involving only the constant 1, and the binary operations of addition and multiplication, with multiplication by 1 not allowed. We obtain an asymptotic formula for the number of arithmetic formulas evaluating to n as n goes to infinity, solving a conjecture of E. K. Gnang and D. Zeilberger."

V3-008908 | OEIS-A243700

The lexicographically earliest sequence of distinct terms with a(1) = 1 such that a(n) divides the sum of the first a(n) terms.

Conjecture: For n > 1000, a(n) falls within 1% of one of the following six values. a(n) = n, 1.576385*n, 1.788185*n, 2.576385*n, 2.788185*n, or 3.576285*n, using floor at the low bound and ceiling at the high bound, inclusive. Conjectured asymptotic slopes of the 6 lines in the function graph are, from low to high: 1, sqrt(3)/3+1, sqrt(3)/6+3/2, sqrt(3)/3+2, sqrt(3)/6+5/2, sqrt(3)/3+3. - _Hugo Pfoertner_, Dec 19 2024

V3-008915 | OEIS-A243924

Irregular triangular array of taxicab norms of Gaussian integers in array G generated as at Comments.

An array G of Gaussian integers is generated as follows: (row 1) = (0), and for n >=2, row n consists of the numbers x+1 and then i*x, where duplicates are deleted as they occur. Every Gaussian integer occurs exactly once in G. The taxicab norm of a Gaussian integer b+c*i is the taxicab distance (also known as Manhattan distance) from 0 to b+c*i, given by |b|+|c|. The norms of numbers in row n are given here in nondecreasing order. Conjecture: the number of numbers in row n is 4n-13 for n >= 5.

V3-008942 | OEIS-A244626

Composite numbers k congruent to 5 (mod 8) such that 2^((k-1)/2) mod k = k-1.

Conjecture 1: if p is an odd prime congruent to {3,5} (mod 8) then 2^((p-1)/2) mod p = p-1. This conjecture has been tested to 10^8. Conjecture 1 is true. With p = 2k+1 then 2^k mod (2k+1) == 2k. So 2k+1 | 2k-2^k. Prime numbers 2k+1 == +-3 (mod 8) are the prime numbers such that 2k+1 | 2^k+1 (Comments A007520). A reflection across the x-axis and +1 translation across the y-axis of the graph (2k-2^k) / (2k+1) gives the graph (2^k+1) / (2k+1). So the k values of both 2k+1 | 2k-2^k and 2k+1 | 2^k+1 are identical. - _Hilko Koning_, Feb 04 2022

V3-008943 | OEIS-A244628

Composite numbers k such that k == 3 (mod 8) and 2^((k-1)/2) == -1 (mod k).

Conjecture 1: if p is a prime congruent to {3,5} mod 8 then 2^((p-1)/2) mod p = p-1. This conjecture has been tested to 10^8. Conjecture 1 is true. With p = 2k+1 then 2^k mod (2k+1) == 2k. So 2k+1 | 2k-2^k . Prime numbers 2k+1 == +-3 (mod 8) are the prime numbers such that 2k+1 | 2^k+1 (Comments A007520). A reflection across the x-axis and +1 translation across the y-axis of the graph (2k-2^k) / (2k+1) gives the graph (2^k+1) / (2k+1). So the k values of both 2k+1 | 2k-2^k and 2k+1 | 2^k+1 are identical. - _Hilko Koning_, Feb 04 2022

V3-008950 | OEIS-A245024

Even numbers n for which lpf(n-1) < lpf(n-3), where lpf = least prime factor.

Conjecture: All differences are 2,4 or 6 such that no two consecutive terms 2 (...,2,2,...), no two consecutive terms 4, while consecutive terms 6 occur 1,2,3 or 4 times; also consecutive pairs of terms 4,2 appear 1,2,3 or 4 times. Conjecture is verified up to n = 2.5*10^7. - _Vladimir Shevelev_ and _Peter J. C. Moses_, Jul 11 2014 The first comment is wrong as stated. This would fix it: for every pair of primes (p,q), p>q>=3, if a(n)==1 (mod p) then a(n) not==3 (mod q). Divisibility by 3 means 6m+4 is in the sequence for all m>0, and 6m never is, while 6m+2 is undetermined. Divisibility by 5 means 30m+26 is always in the sequence, and 30m+8 never is. This proves the above conjecture. - _Jens Kruse Andersen_, Jul 13 2014

V3-008983 | OEIS-A245691

Irregular triangle of Collatz like iteration, x -> 3x, then repeat (x -> ceiling(x/2) if divisible by 3, otherwise x -> 3x) while x != 6.

It is conjectured that the number of steps for the trajectory to arrive at 6 is equal to the number of steps for the Collatz trajectory to arrive at 1 for the same starting value n (n>1), suggesting the length of the n-th row of the irregular array is given by A008908(n). Note that if the starting value of a trajectory in the Collatz sequence is not treated as a potential stopping value, then the conjecture would also be valid for n = 1. Starting with x the first step in this sequence is always to multiply by 3. Thereafter if x <> 6, divide by 2 (rounding up) if x mod 3 = 0, otherwise multiply by 3. If the initial multiply-by-3 step is omitted the sequence still arrives at 6 for any starting value (conjecturally), but the length of the trajectory would no longer be the same as the length of the Collatz trajectory for starting values (n>1) that are divisible by 3.

V3-008998 | OEIS-A245926

Expansion of g.f. sqrt((1-x + sqrt(1-14*x+x^2)) / (2*(1-14*x+x^2))).

Conjecture: a(n) = [x^n] ((1 + x + x^2)*(1 + x)^2/(1 - x)^2)^n. Equivalently, a(n) = Sum_{k = 0..n} Sum_{i = 0..k} Sum_{j = 0..n-k-i} C(n, k)*C(k, i)*C(2*n, j)*C(3*n-k-i-j-1, n-k-i-j). If the conjecture is true then the Gauss congruences a(n*p^k) == a(n*p^(k-1)) (mod p^k) hold for all primes p and positive integers n and k. Calculation suggests that the supercongruences a(n*p^k) == a(n*p^(k-1)) (mod p^(2*k)) hold for primes p >= 5 and positive integers n and k. (End)

V3-008999 | OEIS-A245942

Irregular triangle read by rows of a variation of the Collatz iteration with signature (2,3).

It is conjectured that the trajectory of this Collatz-like iteration arrives at 16 in a finite number of steps for any initial value x, (x>4). The iterative step is divide by 2 and add 2 if even, or multiply by 3 and subtract 5 if odd. For any odd initial value (x>6) the number of steps in the trajectory is the same as the number of steps in the Collatz trajectory starting with floor(x-3)/2. Two variations belong to the same subset if their (a) parameters are the same and their (b) parameters have the same parity. It is conjectured that any variations belonging to the same subset have equal row lengths. Members of the same subset share other properties. For example, if a trajectory of subset type (a=2, b:odd) starts with an odd number, then the function floor((x-b)/2) maps the element values (x) of this trajectory to a trajectory of A245691.

V3-009008 | OEIS-A246054

Numerators of the first rational corners of the mean-median map limit value m(x) for x >= 1/2.

The function m(x) is the limit value of the mean-median map. Start with 0<x<1 and find a new number x_4 so that the median of {0,x,1} equals the mean of {0,x,1,x_4}. Then find a new number x_5 so that the median of {0,x,1,x_4} equals the mean of {0,x,1,x_4,x_5}, etc. It is conjectured by Shultz and Shiflett that for all real x this process ends after finitely many steps. Cellarosi and Munday find a range of x for which this conjecture is true (improving results of Chamberland and Martelli), and an explicit piecewise affine formula for m(x). It is enough to study the case of 1/2 <= x <= 2/3. The first rational corners of the map m(x) to the right of 1/2 are found by Cellarosi and Munday and these are the rationals whose numerators are listed above.

V3-009019 | OEIS-A246452

Let A be the set of all numbers m for which m^2+1 is prime (see A005574). The sequence lists the pairs of numbers (a, b) such that every m > 1 included in A can be written in the form m = a + b for a <= b both in A and a minimum.

Conjecture: for n>1, A005574(n) = a+b where a and b are integers in A005574. By definition, a(2n-1) + a(2n) = A005574(n+1), and a(2n-1) is the minimal solution where the pair (a(2n-1), a(2n)) are both in A005574. The above conjecture says such a pair always exists. - _Jens Kruse Andersen_, Aug 27 2014

V3-009031 | OEIS-A246541

Take the squares of all P_(n+2)-rough numbers less than the (n+1)-th primorial and mod each by the (n+1)-th primorial. There will be a(n) different results.

The conjectured formula from Jon E. Schoenfield is true. This can be seen by considering that each odd prime p has exactly (p+1)/2 quadratic residues (mod p), of which (p-1)/2 are nonzero. The P_(n+2)-rough numbers less than the (n+1)-th primorial comprise all combinations of nonzero residues modulo the first n+1 primes. So for each odd prime p, the p-1 nonzero residues map to (p-1)/2 (nonzero) residues after squaring. - _Bert Dobbelaere_, Aug 09 2023 Conjecture: a(n) = (1/2^n)*Product_{j=1..n} (prime(j+1)-1) = A005867(n+1)/2^n. - _Jon E. Schoenfield_, Feb 20 2019

V3-009071 | OEIS-A247225

a(n) = n if n <= 3, a(4)=5, otherwise the smallest number not occurring earlier having at least one common factor with a(n-3), but none with a(n-1)*a(n-2).

Conjecturally the sequence is a permutation of the positive integers. However, to prove this we need more subtle arguments than were used to prove the corresponding property for A098550. - _Vladimir Shevelev_, Jan 14 2015 For n <= 2000, a(3n-1) is even and both a(3n) and a(3n-2) are odd numbers. I conjecture that this is true for all positive integers n. This conjecture is true iff for all positive integers n, a(3n-1) is even. - _Farideh Firoozbakht_, Jan 14 2015 Conjecturally for every k>=2, as in the case k=1, the sequence (*) is a permutation of the positive integers. For k>=3, at first glance, already the appearance of the number 6 seems problematic. However, at the author's request, _Peter J. C. Moses_ found that the positions of 6 are 83, 157, 1190, 206, ... in cases k=3,4,5,6,... respectively (A254003).

V3-009080 | OEIS-A247335

The curvature of touching circles inscribed in a special way in the larger segment of circle of radius 10/9 divided by a chord of length 4/3.

Refer to comment of A092387. Consider a circle C of radius 10/9 (in some length units) with a chord of length 4/3. This has been chosen such that the larger sagitta has length 2. The smaller sagitta has length 2/9. The input, besides the circle C is the circle C_0 with radius R_0 = 1, touching the chord and circle C. The following sequence of circles C_n with radii R_n, n >= 1, is obtained from the conditions that C_n touches (i) the circle C, (ii) the chord and (iii) the circle C_(n-1). The curvature of the n-th circle, C_n = 1/R_n, n >= 0, is conjectured to be a(n). If one considers the curvature of touching circles inscribed in the smaller segment, the sequence would be A247512. See an illustration given in the link. Conjectures from _Colin Barker_, Sep 18 2014: (Start)

The G.f. conjectured by Colin Barker above follows from the one for Chebyshev's T(n, 19) = A078986(n): (1/(1-x) + (1-19*x)/(1-38*x+x^2))/2 = (1-29*x+10*x^2)/((1-x)*(1-38*x+x^2)). The four term recurrence conjectured by Colin Barker above follows from the expanded g.f. denominator: (1-x)* (1-38*x+x^2) = 1- 39*x + 39*x^2 - x^3.

V3-009087 | OEIS-A247489

Square array read by antidiagonals: A(k, n) = hypergeometric(P, Q, -k^k/(k-1)^(k-1)) rounded to the nearest integer, P = [(j-n)/k, j=0..k-1] and Q = [(j-n)/(k-1), j=0..k-2], k>=1, n>=0.

Conjecture: hypergeometric(P, Q, -k^k/(k-1)^(k-1)) = sum_{j=0.. floor(n/k)} binomial(n-(k-1)*j, j) for n>=(k-1)^2, P and Q as above. (This means for n>=(k-1)^2 the representation is exact without rounding.)

V3-009088 | OEIS-A247556

Exact differential base (a B_2 sequence) constructed as follows: Start with a(0)=0. For n>=1, let S be the set of all differences a(j)-a(i) for 0 <= i < j <= n-1, and let d be the smallest positive integer not in S. If, for every i in 1..n-1, a(n-1) + d - a(i) is not in S, then a(n) = a(n-1) + d. Otherwise, let r be the smallest positive integer such that, for every i in 1..n-1, neither a(n-1) + r - a(i) nor a(n-1) + r + d - a(i) is in S; then a(n) = a(n-1) + r and a(n+1) = a(n) + d.

Conjecture: lim inf_{n->oo} (a(n+1) - a(n))/n = 1/2. Conjecture: a(n) ~ log(log(n))*A025582(n+1), where A025582(m)+1 = A005282(m) is the Mian-Chowla sequence.

V3-009122 | OEIS-A248108

Areas of primitive Heronian triangles K which are perfect squares.

It is known that every positive integer is the area of some rational triangle. Hence for every n > 0 there exists at least one primitive Heronian triangle with area K such that n*k^2 = K for some positive integer k. Therefore for the integer 1 there exists primitive Heronian triangles with area K = k^2. This sequence identifies all such occurrences of square areas from lists of primitive Heronian triangles generated by _Sascha Kurz_ (see link). The sequence excludes repetitive terms and is exhaustive as the Kurz lists searched include all primitive Heronian triangles up to a maximum side length of 6000000 and this sequence only includes areas that do not exceed 6000000 (see _T. D. Noe_ comments at A083875). All 46 terms found are displayed. It is conjectured that this sequence is infinite.

V3-009160 | OEIS-A248833

The curvature of touching circles inscribed in a special way in the larger segment of circle of radius 1/6 divided by a chord of length sqrt(8/75).

Refer to comment of A092387. Consider a circle C of radius 1/6 (in some length units) with a chord of length sqrt(8/75). This has been chosen such that the larger sagitta has length 1/5. The input, besides the circle C, is the circle C_0 with radius R_0 = 1/10, touching the chord and circle C. The following sequence of circles C_n with radii R_n, n >= 1, is obtained from the conditions that C_n touches (i) the circle C, (ii) the chord and (iii) the circle C_(n-1). The curvature of the n-th circle, C_n = 1/R_n, n >= 0, is conjectured to be a(n). If one considers the curvature of touching circles inscribed in the smaller segment (sagitta length 2/15), the sequence would be A248834. See an illustration given in the link.

V3-009169 | OEIS-A249067

Smallest k such that {first digit of j*n, 0<=j<=k} = {0,1,...,9}.

Conjecture: a(n) <= N for all n. Perhaps N can be taken as 81. - _Charles R Greathouse IV_, Oct 20 2014 The conjecture above is true. In fact, a(n) takes on precisely 37 values: 9, 11, 12, 13, 14, 15, 16, 17, 18, 21, 22, 23, 24, 25, 26, 27, 31, 32, 33, 34, 35, 36, 41, 42, 43, 44, 45, 51, 52, 53, 54, 61, 62, 63, 71, 72, and 81. The last of these to occur is a(291) = 31. - _Charles R Greathouse IV_, Mar 17 2018

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009172 | OEIS-A249129

Lexicographically earliest sequence of distinct nonnegative integers such that a(2n) = a(n) + a(n+1) for all n >= 0.

I conjecture that a(n) ~ n. The differences d(n) = a(n)-n are in A249161. The first occurrences of the small differences are at d(0)=1, d(1)=-1, d(2)=0, d(6)=2, d(9)=-2, d(122)=3, d(127)=-3, d(922)=4, d(929)=-4, d(1994)=5, d(2003)=-5, d(3986)=6, d(3997)=-6,... It seems that if d(n) is the first occurrence of k>0, then n is even and d(n+2k-1) = -k is the first occurrence of the opposite value. - _M. F. Hasler_, Oct 22 2014 Is there a proof of the plausible conjecture that every number appears? - _N. J. A. Sloane_, Oct 17 2018

V3-009173 | OEIS-A249167

a(n) = n if n <= 3, otherwise the smallest number not occurring earlier having at least one common Fermi-Dirac factor with a(n-2), but none with a(n-1).

Conjecture: the sequence is a permutation of the positive integers. Conjecture is true. The proof is similar to that for A098550 with minor changes. - _Vladimir Shevelev_, Jan 26 2015

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Vladimir Shevelev_, Dec 15 2014 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009174 | OEIS-A249223

Triangle read by rows: row n gives partial alternating sums of row n of A237048.

For a proof that T(n, k) = |{ d : d|n and k/2 < d <= k }|, for 1 <= k <= row(n), where row(n) is the length of row n, an identity suggested by _Peter Munn_, see the link. A corollary to it is that the number of divisors of n in the half-open interval (row(n)/2, row(n)] equals the width of the symmetric representation of n at the diagonal: T(n, row(n)) = | { d : d|n and row(n)/2 < d <= row(n) } |. See also the comments and conjectures of _Michel Marcus_ in A067742 and A237593. - _Hartmut F. W. Hoft_, Jun 24 2024 Conjecture 1: Every column is a periodic sequence. Conjecture 2: The periods of the columns 1..8 are respectively: 1, 2, 6, 12, 60, 60, 420, 840. Conjecture 3: Column 3 gives [2, 0] together with A115357, hence column 3 gives 2 together with A171182. Conjectures 1 and 2 are true and the answer to question 1 is affirmative. Conjecture 3 and Question 2 are true. Since T237048(n, 1) = 1, T237208(n, 2) = 1 if n odd and 0 if n even, T237048(n, 3) = 1 if 3|n and 0 otherwise, and T237048(n, 4) = 1 if 4|(n-2) and 0 otherwise, equations T249223(n, 3) = 1 - (n mod 2) + delta(n mod 3) and T249223(n, 4) = 1 - (n mod 2) + delta(n mod 3) - delta((n-2) mod 4) hold where delta(k) = 1 if k = 0 and 0 otherwise. With the 3rd column starting at n = A000217(3) = 6, each period starting in a row that is a multiple of 6 is [2 0 1 1 1 0], and appropriate shifts yield A115357 and A171182. With the 4th column starting at n = A000217(4) = 10, each period starting in a row n with 12|(n+2) is [0 0 2 0 0 1 1 0 1 0 1 1], and with a shift of 9 yields the apparently periodic A337976(10), A337976(11), ... (End)

V3-009181 | OEIS-A249457

The numerator of curvatures of touching circles inscribed in a special way in the larger segment of a unit circle divided by a chord of length sqrt(84)/5.

The denominators are conjectured to be A005032. Refer to comments and links of A092387. Consider a unit circle with a chord of length sqrt(84)/5. This has been chosen such that the larger sagitta has length 7/5. The input, besides the unit circle C, is the circle C_0 with radius R_0 = 7/10, touching the chord and circle C. The following sequence of circles C_n with radii R_n, n >= 1, is obtained from the conditions that C_n touches (i) the circle C, (ii) the chord and (iii) the circle C_(n-1). The curvature of the n-th circle is C_n = 1/R_n, n >= 0, and its numerator is conjectured to be a(n). O.g.f.: 5*((1 - 17*x)/(1 - 34*x + 9*x^2) + 1/(1-3*x)) = 10*(1 - 27*x + 30*x^2)/((1 - 34*x + 9*x^2)*(1 - 3*x)) proving the conjecture of Colin Barker above. (End)

V3-009182 | OEIS-A249458

The numerators of curvatures of touching circles inscribed in a special way in the smaller segment of unit circle divided by a chord of length sqrt(84)/5.

The denominators are conjectured to be A169634. Refer to comments and links of A092387. Consider a unit circle with a chord of length sqrt(84)/5. This has been chosen such that the smaller sagitta has length 3/5. The input, besides the circle C, is the circle C_0 with radius R_0 = 3/10, touching the chord and circle C. The following sequence of circles C_n with radii R_n, n >= 1, is obtained from the conditions that C_n touches (i) the circle C, (ii) the chord and (iii) the circle C_(n-1). The curvature of the n-th circle is C_n = 1/R_n, n >= 0, and its numerator is conjectured to be a(n). If one considers the curvature of touching circles inscribed in the larger segment (sagitta length 7/5), the sequence would be A249457/A005032. See an illustration given in the link. O.g.f.: 5*((1 - 13*x)/(1 - 26*x + (7*x)^2) + 1/(1-7*x)) = 10*(1 - 23*x + 70*x^2)/((1 - 26*x + (7*x)^2)*(1 - 7*x)) proving the conjecture of Colin Barker above. (End)

V3-009184 | OEIS-A249507

Length of full iterated word (direct branch and reverse branch) of the Kolakoski sequence A000002 initiated at A000002(n). If the reverse branch is longer than the direct branch, the total length is counted negatively: if A000002(n) = 2, a(n) = 0; if A000002(n) = 1, a(n) = (ld+lr-1)*sign(ld-lr) with ld = max { k | A000002(n-i+1) = A000002(i), 0<i<=k } and lr = max { k | A000002(n-i+1) = A000002(i), 0<i<=k }.

The iterated words are initiated by the 1's in the OK sequence, but the 1's in pairs 11 can only lead to very short iterated words: (1)-1-2(1) or (1)-1-221(2), or the same in reverse order, with values in this sequence of +/-2 or +/-4. On the contrary, each of the single 1's (212) in the OK sequence (except the first) is associated with an iterated word of length at least five, and (conjecture) it is likely that there is no bound to the length of iterated words associated with a single 1. The number of iterated words with the right branch longer than the left seems to be well balanced, so that (conjecture) the limit of partial sums of this sequence could be o(n).

V3-009201 | OEIS-A249759

Primes p such that sigma(p-1) is a prime q.

Conjectures: 1) sequence is finite; 2) sequence is a subsequence of A019434 (Fermat primes); 3) sequence consists of Fermat primes p such that sigma(p-1) is a Mersenne prime; 4) a(n) = (A249761(n)+3)/2. Conjecture: 3 is the only number n such that n and sigma(n+1) are both prime. Conjecture: subsequence of A256438 and A278741. Conjecture: also primes p such that tau(p-1) is a prime q; corresponding values of primes q are 2, 3, 5, 17. (End)

V3-009202 | OEIS-A249760

Numbers k such that k+1 and sigma(k) are both primes.

Conjectures: (1) sequence is finite; (2) a(n) + 1 is a Fermat prime (A019434); (3) sigma(a(n)) is a Mersenne prime (A000668). Subsequence of A023194, and by a comment in that entry it follows that each term is a prime power. From that conjectures (2) and (3) above easily follow. - _Jeppe Stig Nielsen_, Jan 13 2015

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009221 | OEIS-A249943

a(n) = smallest k such that the numbers 1..n appear among A098550(1), ..., A098550(k), or a(n) = 0 if there is no such k.

The conjecture that all terms are positive is equivalent to the known conjecture that A098550 is a permutation of the positive integers. The author conjectures that a(n)/n <= a(19)/19 = 43/19. _Peter J. C. Moses_ verified that the strict inequality holds for 19 < n <= 1.1*10^5. - _Vladimir Shevelev_, Dec 06 2014

V3-009238 | OEIS-A250030

a(n) is the number of iterations of A008474 needed to reach 5, starting at n, where A008474(Product p_i^e_i) = Sum(p_i+e_i).

Conjecture 1: for m > 4, by iterating the map m -> A008474(m) one always reaches 5. Tested for m up to 320000. Conjecture 2: Let S(n) be the sum of the first a(n) numbers in the n-to-5 orbit, i.e., the sum of all the numbers in the orbit without 5. Except for n in [8,9], S(n) is not divisible by n. Verified for n up to 10^6. - _Ivan N. Ianakiev_, May 06 2015 Proof outline for Conjecture 1: 3. The only thing needed to complete the proof is to exhaustively confirm the conjecture for all numbers in [5, 29] that were not handled in items 1 and 2 above, i.e., 5, 6, 8, 9, 10, 11, 13, 14, 15, 21, 22, 25, 26. V3-009250 | OEIS-A250120

Coordination sequence for planar net 3.3.3.3.6 (also called the fsz net).

The Mathematica notebook can compute 30 or 40 iterations, and colors them with period 5. You could also change out images if you want to. These graphs are better for analyzing 5-iteration chunks of the pattern. You can see that under iteration all fragments of the circumferences are preserved in shape and translated outwards a distance approximately sqrt(21) (relative to small triangle edge), the length of a long diagonal of larger rhombus unit cell. The conjectured recurrence should follow from an analysis of how new pieces occur in between the translated pieces. - _Bradley Klee_, Nov 26 2014 Based on computations of Darrah Chavey, Bradley Klee, and Maurizio Paolini, it is conjectured that the first differences of this sequence are 4, 4, 6, 4, 5, 5, 4, 6, 4, 5, 5, 4, 6, 4, 5, 5, ..., that is, 4 followed by (4,6,4,5,5) repeated. All the above conjectures are true - for proof see link to my article with Chaim Goodman-Strauss. - _N. J. A. Sloane_, Jan 14 2018; link added Mar 26 2018

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009253 | OEIS-A250131

a(n) is the odd part of the digital sum of 3^n divided by the maximal possible power of 3.

Consider the sequence {b(n)}, such that b(1)=2, b(2)=3, and for n>=3, b(n)=a(n-2). We conjecture that, if we apply the Eratosthenes-like sieve to b(n) and remove 1's, then we obtain a sequence of primes. _Peter J. C. Moses_ noted that these primes follow with some perturbation of order. For example, 73 appears before 71. Similarly, 101 and 103 appear before 97.

V3-009373 | OEIS-A251743

Pairs of nodes in a complete binary tree that are at an absolute height difference of less than 2 from each other.

Conjectures from _Colin Barker_, Dec 09 2014: (Start)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Dhruv Matani_, Dec 07 2014 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009374 | OEIS-A251758

Let n>=2 be a positive integer with divisors 1 = d_1 < d_2 < ... < d_k = n, and s = d_1*d_2 + d_2*d_3 + ... + d_(k-1)*d_k. The sequence lists the values a(n) = floor(n^2/s).

Conjecture: Terms x, where a(x)=n, x=p#k/p#j, p#i is the i-th primorial, k>j is suitable large k and j is the number of primes less than n. As an example, n=9, x = p#7/p#4 = 2431. For n=10, x = p#6/p#4 = 143 although 121 = 11^2 is the least x where a(x)=10 (see formula section). For n=8, x = p#12/p#4, p#13/p#4, p#14/p#4, p#15/p#4, p#16/p#4, etc. But is p#12/p#4 the least such x? - _Robert G. Wilson v_, Dec 18 2014 Adamczewski includes proof abstract regarding Wilson's conjecture in linked article. - _Michael De Vlieger_, Aug 19 2026

V3-009390 | OEIS-A252739

a(n) = A252738(n) / n.

Note how 6, 720 and 612360000 occur in A244743 as its 0th, 4th and 8th term, from which my bold conjecture that A244743(12) or A244743(16) = 1697781042840960000000000. According to preliminary results from _Janis Iraids_, the value of A005245(a(5)) = ||1697781042840960000000000|| = 160, while ||1697781042840960000000000 - 1|| = 169, which lays to rest my naive conjecture above, as 169 - 160 is neither 12 nor 16. Note also how 5, 719 and 612359999 are all primes, while a(5)-1 factorizes as 1697781042840959999999999 = 13 * 89443 * 908669 * 1606890407869. - _Antti Karttunen_, Dec 20 2015

V3-009430 | OEIS-A253174

For a permutation of the positive integers B={b(k)}, denote L_B(n) = Sum_{k=1..n} lambda(b(k)), where lambda(n) is Liouville's function (A008836). In this sequence, a(n) = L_B(n) in case B = A098550.

In case B=A000027 (the natural numbers), G. Polya (1919) conjectured that L_B(n)<=0, for n>=2. But this was disproved in 1958 by B. Haselgrove, and in 1980 M. Tanaka found the smallest counterexample, 906150257. However, for this sequence we conjecture that a(n)>=0 for all n other than 3. A reason for our conjecture is the later appearance of primes in A098550 than in A000027. By our conjecture, among the first N terms of A098550, the terms with odd s are never in the majority, if N is other than 3. _Peter J. C. Moses_ verified the conjecture up to 2.5*10^5 and, moreover, in this range a(n)>0 for n>6.

V3-009448 | OEIS-A253238

Number of ways to write n as a sum of a perfect power (>1) and a prime.

In the past, I conjectured that a(n) > 0 for all n>24, but this is not true. My PARI program found that a(1549) = 0. I also asked which a(n) are 1. For example, 331 is a de Polignac number (A006285), so it cannot be written as 2^n+p with p prime, and 331-6^n must divisible by 5, 331-10^n must divisible by 3, ..., 331-18^2 = 331-324 = 7 is prime (and it is the only prime of the form 331-m^n, with m, n natural numbers, m>1, n>1), so a(331) = 1. Similarly, a(3319) = 1. Conjecture: a(n) > 1 for all n > 3319. This conjecture is not true: a(1771561) = 0. (See A119748) Another conjecture:

For every number m>=0, there is a number k such that a(n)>=m for all n>=k. Another conjecture: Except for k=2, first occurrence of k must be earlier then first occurrence of k+1.

V3-009450 | OEIS-A253246

Pisano period of A006190 to mod prime(n).

If the generalized Wall's conjecture to A006190 is true, then we can calculate A175182(m) when m is a prime power since for any k>=1 : A175182(prime(n)^k)=a(n)*prime(n)^(k-1). For example: A175182(2^k)=3*2^(k-1)=A007283(k-1). In fact, the conjecture fails on p=241, and this is the only counterexample below 10^8.

V3-009483 | OEIS-A253809

Array of pairs (x,y) of Markoff triples (x,y,z) with x <= y <= z, for z given in A002559.

Frobenius' conjecture on Markoff triples is that the maximal member z of the triple of positive integers (x,y,z), satisfying x^2 + y^2 + z^2 - 3*x*y*z = 0, with x <= y <= z, determines x and y uniquely. Also, each entry from A002559 (Markoff numbers) is conjectured to appear as a maximal member z. If an entry A002559(n) should not appear as z then one puts z(n) = 0 and row n will be 0, 0. If this Frobenius conjecture is true then the row length of this array is always 2, and only positive numbers appear.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009492 | OEIS-A254077

a(n) = n if n <= 3, otherwise the smallest number not occurring earlier such that gcd(a(n),a(n-2)) > gcd(a(n),a(n-1)).

Conjecture: The sequence is infinite (that is, a(n) always exists). Conjecture: The sequence is a permutation of the natural numbers. Conjectures: 1) For k>=3, except for k=5, if a(n) = prime(k), then a(n-2) = 2*prime(k) and a(n+2) = 3*prime(k). This conjecture was verified by _Peter J. C. Moses_ for n <= 5000. - _Vladimir Shevelev_, Feb 09 2015. This conjecture verified for n <= 10^7. - _Ray Chandler_, Apr 02 2015. Extended to n <= 10^9. - _John Mason_, Jun 08 2016 2) For k>=3, except for k=4, if a(n)=prime(k)^2, then a(n-2) = prime(k)^2 + prime(k). This conjecture was verified by _Peter J. C. Moses_ for n <= 35000. - _Vladimir Shevelev_, Feb 12 2015. This conjecture verified for n <= 394349. - _Ray Chandler_, Mar 07 2015. This conjecture is false - for n = 4488245, a(n) = 2137^2, but a(n-2) = 2137^2 + 2*2137. - _Ray Chandler_, Mar 30 2015. Next are n = 30655601, a(n) = 5581^2, but a(n-2) = 5581^2 + 2*5581, and n = 922447261, a(n) = 30577^2, but a(n-2) = 30577^2 + 2*30577. - _John Mason_, Sep 15 2016 Theorem: If a(n-2) is prime AND a(n) EXISTS then a(n) is a multiple of a(n-2). For: by sequence definition, assuming a(n-2) = p, prime, then gcd(a(n),p) > gcd(a(n),a(n-1)); hence gcd(a(n),p) > 1; but p is prime and has only 1 and itself as divisors; so gcd(a(n),p)=p, and so a(n) is a multiple of p. (Weaker than the similar conjecture above.) - _John Mason_, Apr 15 2015 [WORDS IN CAPS ADDED BY _N. J. A. Sloane_, Apr 16 2015] Conjecture. The primes exist as elementary terms of the sequence in ascending order. - _John Mason_, Apr 17 2015 Conjecture. For any n > 4, the lowest value x missing from a(1) thru a(n) is prime. - _John Mason_, Apr 29 2015. In fact, taking into account that, apparently, prime p appears in the sequence at position circa 2p, we may conjecture that the lowest k values missing from a(1) thru a(n) are prime, where k = pi(n)-pi(n/2) - see A000720. - _John Mason_, Jun 03 2015 Conjecture. For n > 778, if a(n) < n, then a(n) is prime. This has been confirmed for n through 10^9. - _John Mason_, Jun 03 2015 [Corrected, following suggestion by _John P. Linderman_, by _John Mason_, May 28 2017] Conjecture. As for "Conjecture 1" above, which is its mirror image, except for n=2,3,21, corresponding to primes 2,3,11, if a(n-2)=mp

is the first occurrence of prime p as a factor in the sequence, then m=2 and a(n)=p. Also, if a(n-2)=mp is the first occurrence of prime p as a factor in the sequence, then p does not divide a(n-1). - _John Mason_, May 31 2016 Theorem 4. If a(n) = 2p is the first term having p (prime) as a factor, then a(n+2), if it exists, is either p or 2u for some integer u such that 2u < p. (Note that it is conjectured to be always p, and observation confirms the conjecture.) Theorem 5, generalization of Theorem 4. If a(n) = cp is the first term having p (prime) as a factor (n >3), and as a consequence c=k^i for prime k and i>0, then a(n+2), if it exists, is either p or ku for some integer u such that ku < p. (Note that it is conjectured to be always p, and observation confirms the conjecture.) Conjecture: After 2 and 3, no two primes are consecutive terms. This conjecture is derivable from the previous conjecture : "For k>=3, except for k=5, if a(n) = prime(k), then a(n-2) = 2*prime(k) ...". For, if sequence has terms z,2p,2q,p,q for primes p & q, then gcd(2q,z)>gcd(2q,2p)=2. Hence q divides z. So terms are mq,2p,2q,p,q. So we could have used q in place of 2q. - _John Mason_, May 28 2017

V3-009496 | OEIS-A254311

Set of all natural numbers m such that m < S(m), where the function S is as defined in A257480.

Conjecture: A254312 is a permutation of this sequence.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _L. Edson Jeffery_, May 03 2015 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009497 | OEIS-A254312

Rectangular array A read by upward antidiagonals in which the entry in row n and column k is defined by A(n,k) = (2^a(n)*(6*k - (3 - (-1)^a(n))*(1 - (-1)^n)/2) - 2^n + 4)/6, n,k >= 1, where {a(n)} is the Beatty sequence A117630 defined by a(n) = floor(n*log(3)/log(3/2)).

Conjecture: The array A contains without duplication all natural numbers m such that m < S(m), where the function S is as defined in A257480; i.e., the sequence is a permutation of A254311.

V3-009498 | OEIS-A254337

Lexicographically earliest sequence of distinct numbers such that no sum of consecutive terms is prime.

I conjecture that the sequence contains all even numbers > 2 and no odd number beyond 1. If so, we must simply ensure that the sum a(1)+...+a(n) is not prime, which is always possible for one of the three consecutive even numbers {2n, 2n+2, 2n+4}. As a consequence, it would follow that a(n) ~ 2n.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _M. F. Hasler_, Jan 28 2015 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009499 | OEIS-A254439

Median of terms of A254296 in the range (3^(n-1)+1)/2 to (3^n-1)/2.

From conjectured formula, it appears that next terms are 1107102779611719118, 11090084422457163934046, 3020025292945963031585836 42. - _Benedict W. J. Irwin_, Nov 16 2016 Conjecture: for n>3, a(n+3) = Sum_{i_1=1..2} Sum_{i_2=1..3*i_1-1} ... Sum_{i_n..3*i_(n-1)-1} (3*i_n - 1). - _Benedict W. J. Irwin_, Nov 16 2016

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009500 | OEIS-A254460

a(n) is the number of predecessors of the all-ones state of the binary cellular automaton on the n X n grid graph with edges joining diagonal neighbors as well as vertical and horizontal neighbors, whose local rule is f(i,j) = sum of the state at vertex (i,j) and the states at all of its neighbors mod 2.

Later we discovered the relationship to Sutner's paper. A corollary of that paper is that a(n) > 0 for all n. An obvious conjecture is that a(n) = 1 for n mod 3 = 0 or 1 and if n mod 3 = 2 then a(n) = 2^(2n-1).

V3-009537 | OEIS-A255617

a(n) is the smallest even term in A098550 less than 2*prime(n) but occurring after 2*prime(n); a(n)=0 if no such term exists.

Conjecture: for n>=5, positive a(n) > prime(n). Together with the known conjecture that, for n>=26, 2*prime(n) is the first multiple of prime(n) appearing in A098550, this conjecture would easily implies that the primes in A098550 occur in the natural order. (Indeed, if 101<=P<Q, then, as known, the first multiple of P, 2*P, appears earlier than the first multiple of Q, 2*Q. By the conjecture, after 2*P there cannot appear any even number <P; thus if a(n)=2*P, then a(n+2)=P appears before 2*Q.)

V3-009547 | OEIS-A255905

Expansion of exp(Sum_{n >= 1} R(n,u)*x^n/n), where R(n,u) denotes the n-th row polynomial of A086646.

The above conjecture can be extensively generalized. The elements of A000364 can be expressed in terms of the Euler polynomial E(n,x) as A000364(n) = (-1)^n*2^(2*n)*E(2*n,1/2). This suggests considering polynomials of the form P(n,u) = Sum_{k = 0..n} binomial(2*n,2*k)*A(n-k)*u^k, where the sequence A(n) is defined in terms of the Euler polynomials. Calculation suggests that in the expansion of exp(Sum_{n >= 1} P(n,u)*x^n/n), the coefficient polynomials in u are always integer polynomials for the following choices of A(n): The present triangle (up to signs) is simply the case of conjecture 1 with the choices h = 1 and k = 2. Similar conjectures can be made if, in the above definition of the polynomial P(n,u), the factor equal to binomial(2*n,2*k) is replaced by binomial(m*n,m*k) for some fixed m = 1,2,3,....

V3-009569 | OEIS-A256174

Boomerang Fractions: Starting with 1, on the first step add 1/n, and on subsequent steps either add 1/n or take the reciprocal. a(n) = minimal number of steps needed to return to 1.

At that event, the sequence was calculated with conjectures for the 11th and 13th terms: 4, 9, 7, 20, 6, 33, 13, 23, 16, 62?, 8, 75?, 18, 17, 25. - _Gordon Hamilton_, Apr 02 2015 Additional values: a(35) = 25, a(48) = 29. Upper bounds: a(n) <= n^2. Add n(n-1) times, take the reciprocal and add n-1 times. a(bc) <= c(b^2-1) + 1. Add n(b-1) times, take the reciprocal and add (b-1)c times. For c > b, a(bc) <= c^2-b^2 + 1. Add c(c-b) times, take the reciprocal and add (c-b)b times. In particular, for n = b(b+1), a(n) <= 2(b+1). The minimum of these bounds give a(n) for n = 2, 3, 4, 6, 8, 10, 12, 15, 20, 30, 35, 42, 48, 56, 72, 90, 110, 132. Exhaustive search show that a(b*(b+1)) = 2(b+1) for b <= 12 which seems to support the conjecture that this is true for all b. - _Chai Wah Wu_, Apr 02 2015 Minimizing the total number of steps under the additional constraint that the number of consecutive "add 1/n" steps immediately before each "take the reciprocal" step must be a multiple of n gives the following upper bound on a(n) for n in [2..13]: 4, 9, 7, 20, 10, 33, 13, 23, 16, 62, 19, 75. Note that these values match the known exact values of a(n) at n = 2, 3, 4, 5, 7, 8, 9, 10, and 11, as well as the conjectured value at n = 13. See the Links for a file giving the value of this upper bound, and a solution at that number of steps, for all n in [2..10000]. Conjecture: For all prime values of n, a(n) is exactly the minimal number of steps to return to 1 under the added constraint that the number of consecutive "add 1/n" steps immediately before each "take the reciprocal" step must be a multiple of n. A stronger conjecture: The above conjecture applies not only when n is prime, but also when n is a prime power. If this is true, then it appears that If the above conjectures about a(n) where n is a prime or prime power are correct, then a(17)..a(49) are 111, 16, 126, 10, 29, 34, 171, 15, 88, 40, 65, 27, 217, 12, 235, 49, 66, 52, 25, 22, 310, 58, 31, 19, 345, 14, 362, 66, 49, 70, 396, 29, 213; a(50) seems very likely to be 73. - _Jon E. Schoenfield_, Apr 20 2015

V3-009589 | OEIS-A256535

The largest number of T-tetrominoes that fit within an n X n square.

Shuxin Zhan proved that it is not possible to tile a square of side 4m+1 or 4m+3 with T-tetrominos and a single monomino. Thus there must be at least 5 empty squares in any partial tiling by T-tetrominos. This bound is achieved for tilings in 5 X 5, 7 X 7, 9 X 9 and 11 X 11 squares. Robert Hochberg proved that for n > 11, there must be either 5 or 9 empty squares. He conjectured that 5 is always enough.

V3-009594 | OEIS-A256598

Irregular triangle where row n contains the odd terms in the Collatz sequence beginning with 2n+1.

The Collatz function is an integer-valued function given by n/2 if n is even and 3n+1 if n is odd. We build a Collatz sequence by beginning with a natural number and iterating the function indefinitely. It is conjectured that all such sequences terminate at 1. In this triangle, row n is made up of the odd terms of the Collatz sequence beginning with 2n+1. Therefore, it is conjectured that this sequence is well-defined, i.e., that all rows terminate at 1.

V3-009656 | OEIS-A257883

Sequence (a(n)) generated by Algorithm (in Comments) with a(1) = 0 and d(1) = 0.

Conjecture: if a(1) is a nonnegative integer and d(1) is an integer, then (a(n)) is a permutation of the nonnegative integers (if a(1) = 0) or a permutation of the positive integers (if a(1) > 0). Moreover, (d(n)) is a permutation of the integers if d(1) = 0, or of the nonzero integers if d(1) > 0.

V3-009657 | OEIS-A257886

Least positive m such that floor(n! / (2*(floor(n/2)!))) + m is prime.

Conjecture: No term is composite (similar conjecture to A033932 for a different expression).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _David Morales Marciel_, May 11 2015 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009658 | OEIS-A257889

Terms satisfy: a(2*n) = a(n)*b(n) and a(2*n+1) = a(n)*b(n+1) for n>=0 with a(0)=1, where A(x)^2 = Sum_{n>=0} b(n)*x^n and g.f. A(x) = Sum_{n>=0} a(n)*x^n.

5 divides a(3*2^n) for n>=0 (conjecture). 5 does not divide a(3*2^n - 1) for n>=0 (conjecture).

V3-009683 | OEIS-A258024

Natural numbers n such that the iteration of the function floor(tan(k)) applied to n eventually reaches [the fixed point] 1 (or any larger integer if such fixed points exist), where k is interpreted as k radians.

It is conjectured that applying the function floor(tan) k times, with k sufficiently large, on the finite sequence floor(tan(n)), n=0..N, the result is a sequence (cf. A258021) composed only of 0's and 1's for all values of N. The original definition was: "Numbers n with property that floor(tan(n)) reduces to 1 (instead of 0) when the function is applied repeatedly to n with deep enough nesting level." If the conjecture above is true, then the new, in theory more inclusive definition produces exactly the same sequence. It has been checked that for at least up to A249836(13) = 1108341089274117551 there are no other strictly positive fixed points beside 1. - _Antti Karttunen_, May 26 2015 According to _Jan Kristian Haugland_ (cf. link): It is an open problem whether (tan n) > n for infinitely many n, although it has been proved that |tan n| > n for infinitely many n. - _Daniel Forgues_, May 27 2015

V3-009701 | OEIS-A258333

Number of (primitive) weird numbers of the form 2^n*p*q, with odd primes p < q.

However, p is usually not unique, e.g., for k=3, p=19 we have two pwn (with q=61 and q=71), and for k=5, p=71 yields two pwn (for q=523 and q=541) and p=67 yields three pwn (for q=887, 971 and 1021). I conjecture that there is an increasing number of pwn with, e.g., p=nextprime(2^(k+1)). Also, if 2^k p q and 2^k p' q are both weird, then usually 2^k p" q is weird for all p" between p and p'. There is one exception [p, p', q] = [2713, 2729, 8191] for k=10, five exceptions [6197, 6203, 12049], [6113, 6131, 12289], [6113, 6131, 12301], [6121, 6133, 12323], [5441, 5449, 16411] for k=11, and seven exceptions for k=12. These exceptions occur when q/p is close to an integer, (p, q) ~ (3/4, 3/2)*2^(k+2) or (2/3, 2)*2^(k+2). - _M. F. Hasler_, Jul 16 2016

V3-009709 | OEIS-A258663

Numbers n such that 9n-1 is prime.

It is my conjecture that the integer formed by the repeating digits in the decimal fraction a(n)/(a(n)*9-1) is the smallest integer such that rotating the digits to the left produces a number which is ((a(n)+1)/a(n)) times larger. An additional conjecture is that the values x in this sequence are the only values where rotating an integer one to the left produces a value (x+1)/x times as large. For example, the conjecture is that there are integers i that when rotated one to the left produce the value 3i/2, 7i/6 and 9i/8, but none that produce the value 2i/1, 4i/3, 5i/4, 6i/5 or 8i/7. The second conjecture is false. For example, 225806451612903*(8/7) = 258064516129032, or 45 * (6/5) = 54 or 230769*(4/3)=307692. - _Giovanni Resta_, Jul 28 2015

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009788 | OEIS-A259922

a(n)= Sum_{2 < prime p <= n} c_p - Sum_{n < prime p < 2*n} c_p, where 2^c_p is the greatest power of 2 dividing p-1.

In connection with this, it is natural to conjecture that there exists a number N such that a(n)>0 for all n >= N.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Vladimir Shevelev_, Jul 09 2015 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009789 | OEIS-A259934

Infinite sequence starting with a(0)=0 such that A049820(a(k)) = a(k-1) for all k>=1, where A049820(n) = n - (number of divisors of n).

Therefore, d(a(k+1) + d(a(k+1))) = d(a(k+2))= d(a(k+1)), i.e., a(k+1) is in A175304. Thus, if there are infinitely many pairs of the same consecutive terms of A259935, then A175304 is infinite (see there my conjecture). (End) If multiple apparently infinite branches would occur at some point of computing, then even if the "lexicographically earliest" condition were then added to the definition, it would not help us much (when computing the sequence), as we would still not know which of the said branches were truly infinite. [See also _Max Alekseyev_'s latter Jul 9 2015 posting on SeqFan-list, where he notes the same thing.] Note that many of the derived sequences tacitly assume that the uniqueness-conjecture is true. See also comments at A262693 and A262896.

V3-009865 | OEIS-A261246

Positive integers D such that the generalized Pell equation X^2 - D Y^2 = 2 is soluble.

Conjecture: The sequence consists of all numbers D not a square and even D = 2*d has odd d with prime factors of the form 1 or 7 (mod 8). Odd D has prime factors of the form 1 or 7 (mod 8) but there is an odd number of primes of the form 7 (mod 8). The following will prove that these conditions for D are necessary in order to have solutions. This conjecture is false. For the odd D case see the counterexamples in A263010, and for the even D in A264352. - _Wolfdieter Lang_, Nov 12 2015

V3-009866 | OEIS-A261249

Number of classes of proper solutions of the Pell equation x^2 - D(n) y^2 = +4 for D(n) = A079896(n), n >= 1.

Conjecture: For even D(n), i.e., D from 4*A000037, and a(n) = 0 one finds for r(n) = D(n)/4 coincidence with Conway's so-called rectangular numbers A007969. The first D values are 8, 20, 24, 40, 48, 52, 56, 68, 72, 80, ... This is equivalent to the conjecture that X^2 - r*y^2 = +1 has an even fundamental positive solution y = y0 precisely for the numbers A007969 (because x has to be even, x = 2*X, and whenever y0 is even all y solutions are even). See A261250 and A262024 for the y0 and x0 values, respectively.

V3-009881 | OEIS-A261314

Rocket Sequence 34: a(0)=34, a(n) = A073846(a(n-1)).

A given sequence c(n) can be one of two kinds. It can either be periodic with c(m) = c(0) for some m, or it can include infinitely many distinct values. R#(n) is finite for all n<34. However, this sequence has been checked up to a(86) = 1091595086717 without reaching 34. Instead it seems to be slowly climbing in value in both the negative and positive directions. Hence, its period is either extremely large or nonexistent (infinite). I conjecture that the latter is the case. Thus I dubbed the sequence "Rocket" because, as opposed to the "Hailstone" sequences, it never seems to "fall".

V3-009915 | OEIS-A261699

Triangle read by rows: T(n,k), n >= 1, k >= 1, in which column k lists positive terms interleaved with k-1 zeros, starting in row k(k+1)/2. If k is odd the positive terms of column k are k's, otherwise if k is even the positive terms of column k are the odd numbers greater than k in increasing order.

Conjecture: the positive terms in row n are the odd divisors of n. Proof of the conjecture: let n = 2^m*s*t with s and t odd. The property stated in A237048 verifies the conjecture with odd divisor k <= A003056(n) of n in position k and odd divisor t > A003056(n) in position 2^(m+1)*s. Therefore reading in row n the nonzero odd positions from left to right and then the nonzero even positions from right to left gives all odd divisors of n in increasing order. - _Hartmut F. W. Hoft_, Oct 25 2015

Lexicographically earliest sequence of distinct terms such that the absolute difference of two successive terms is a power of 10, and can be computed without carry.

Conjectured to be a permutation of the nonnegative integers. See A261729 for putative inverse.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Paul Tek_, Aug 30 2015 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-009918 | OEIS-A261728

a(1)=1; a(2*n) = 3*n; for odd n>1, a(n) is the smallest number not already present which is entailed by the rules (i) k present => 3*k+1 present; (ii) 2*k present => k present.

Proof. We use induction. The induction hypothesis (IH) is that the lemma is true for every even c<=2*k and odd c<=2*k+1. On the other hand, the statement 'the sequence is a permutation of the positive integers' conjecturally is equivalent to the (3*n+1)-conjecture.

V3-009921 | OEIS-A261862

Terms in A261524 that are not multiples of earlier terms.

In A261524 it is conjectured that degree(gcd(1 + x^(Zs(d,2,1)), 1 + (1+x)^(Zs(d,2,1))) > 0 for every odd number d != 1, 15, 21, where Zs(d,2,1) is the d-th Zsigmondy number with parameters (2,1) (A064078). Since Zsigmondy numbers with different indices are coprime, if this conjecture is true, then there exists a term of this sequence k with ord(2,k) = d, and k must be a divisor of Zs(d,2,1) for every odd number d != 1, 15, 21. Here ord(a,k) is the multiplicative order of 2 modulo k. In A261524 we show that this conjecture is true for powers > 1 of a prime r >= 5, so there are infinitely many terms in this sequence. One may conjecture that, if k is a term with ord(2,k) = d for even d, then k is a divisor of Zs(d,2,1)*Zs(d/2,2,1). This fails for (d,k) = (20,11275), (40,16962275), (44,165965585), ... Conjecture: a term with ord(2,k) = d for even d exists if and only if d != 12 or 2*p, where p is any Mersonne exponent. (End)

V3-009929 | OEIS-A261953

Start with a single equilateral triangle for n=0; for the odd n-th generation add a triangle at each expandable side of the triangles of the (n-1)-th generation (this is the "side to side" version); for the even n-th generation use the "vertex to vertex" version; a(n) is the number of triangles added in the n-th generation.

For finite sets of random points in the real plane with exactly n nearest neighbors, a(n) for n >= 2 is a lower bound for the maximal number of points. Conjecturally, a(n) equals this number. We conjecture that a(n) is optimal. This claim is true if the following assumptions hold:

V3-009943 | OEIS-A262136

Number of distinct fractional parts of the numbers Sum_{i=j..k} (-1)^i/i with 1 <= j <= k <= n, where the fractional part of x is given by x - floor(x).

Conjecture: (i) Suppose that Sum_{i=j..k} (-1)^i/i and Sum_{r=s..t} (-1)^r/r with 0 < min{2,k} <= j <= k, 0 < min{2,t} <= s <= t and j <= s have the same fractional part, but the ordered pairs (j,k) and (s,t) are different. Then Sum_{i=j..k} (-1)^i/i = Sum_{r=s..t} (-1)^r/r. Moreover, if j is odd, then j > 1, k = j*(j+1) and (s,t) = (j+2,j*(j+1)-1); if j is even, then either (k = j+1 and s = t = j*(j+1)), or (k = j*(j+1)-1 and (s,t) = (j+2,j*(j+1))). This is an analog of the conjecture in A261878. Part (i) of the conjecture implies that a(n) = n*(n-1)/2 + 2 - floor((sqrt(4n+1)-1)/2) - floor((sqrt(4n+1)-1)/4) for all n > 1.

V3-009990 | OEIS-A262765

a(n) = the number of ways that at least two distinct primes <= prime(n) sum to a prime.

Conjectures: The plot does, in fact, suggest that a(n)/a(n-1) "generally increases" (i.e., generally a(z*n)/a(z*n-1) > a(n)/a(n-1), when z is sufficiently large). In other words, the peaks and the troughs tend to increase, with peaks tending to be higher than next trough. This behavior is consistent with the observation about "general increase" in conjecture iii, as n increases to infinity. However, the plot does not show that generally a(n)/a(n-1) > a(n+1)/a(n), or that there can't be a maximum value of a(n)/a(n-1) after which all other values decrease (two completely different issues). Conjecture ii is clearly false since a(n)/(n-1) is slightly > 2 for a few terms 11 <= n <= 400 (n = {333..340}), therefore weakening the observation in conjecture iii that the limiting ratio must be < 2. (End)

V3-010005 | OEIS-A262896

If n is in A262892, a(n) = A259934(n), otherwise the largest term in A045765 from which A259934(n) can be reached by iterating A049820, without visiting any other (larger) term of A259934.

Note that without (so far undetected) regularity in A262509, there is no a priori upper bound for the value of a(n), and for some n this might not even be finite, if it happens that contrary to its conjectured nature, A259934 is not the unique infinite component, but just the lexicographically earliest instance of multiple infinite branches of the tree. In that case we might consider this sequence to be well-defined only up to the least such node branching to multiple infinite components, or alternatively, we might mark the nonfinite values at those points with -1.

V3-010006 | OEIS-A262922

a(1)=1; for n>1, a(n) = a(n-1) + n + 2 if a(n-1) and n are coprime, otherwise a(n) = a(n-1)/gcd(a(n-1),n).

Quasi-periodic sequences exist only for R=0,1,2 or 3 in a(n) = a(n-1) + n + R. For R=0,1,2 all starting values give a quasi-periodic sequence. The respective loop is (1,x) for R=0, (1,x,2x,2) for R=1, (1,x,2x,x) or (x,2x) for R=2. For R=3 only some starting values converge to a 6-loop (4x+2,2x+1,3x+6,x+2,2x+9,3x+17). Conjecture: For R>=4 the recurrence is not quasi-periodic.

V3-010028 | OEIS-A263010

Exceptional odd numbers D that do not admit a solution to the Pell equation X^2 - D Y^2 = +2.

Necessary conditions for nonsquare odd D were shown there to be D == 7 (mod 8), without prime factors 3 or 5 (mod 8) in the composite case. Thus only prime factors +1 (mod 8) and -1 (mod 8) can appear, and the number of the latter is odd. It has been conjectured that all such numbers D appear in A261246, but this conjecture is false as the present sequence shows. For counterexamples to the conjecture in A261246 for even D see A264352.

V3-010046 | OEIS-A263399

Number of ordered pairs (k, m) with 0 < m < n and |k| < prime(m)^2 such that (k+prime(m+1)^2)/(k+prime(m)^2) = (k+prime(n+1)^2)/(k+prime(n)^2).

Conjecture: Let k, m and n be integers with 0 < m < n and -2*prime(m) < k <= 2*prime(m). If (k+prime(m+1)^2)/(k+prime(m)^2) = (k+prime(n+1)^2)/(k+prime(n)^2), then we must have k = -9, m = 5 and n = 11. The conjecture essentially implies that for each k = -3..10 all the ratios (prime(n+1)^2+k)/(prime(n)^2+k) (n = 1,2,...) are pairwise distinct. We have verified that for any k = -1, 1 the ratios (prime(n+1)^2+k)/(prime(n)^2+k) (n = 1..110000) are indeed pairwise distinct.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010058 | OEIS-A263722

Integers k > 0 such that k^2 + p^2 is composite for all primes p.

Conjecture: All terms are odd. An equivalent conjecture in A263977 is that if k > 0 is even, then k^2 + p^2 is prime for some prime p. We have checked this for all k <= 12*10^7. An odd number k is a term if and only if k^2 + 2^2 is composite, since k^2 + p^2 is even and > 2 (hence composite) for all odd primes p. Thus if the Conjecture is true, then the sequence is simply odd k such that k^2 + 4 is composite. The sequence of odd k, such that k^2 + 4 is prime, is A007591.

V3-010076 | OEIS-A264038

Convolution of Lucas and Jacobsthal numbers.

Referring to the simplicity of definition (II), the authors formulate the following open question: "Since the convolution takes such a simple form, we ask whether it is possible to obtain a purely combinatorial proof of this result." I would suggest another open question: Are there convolutions of other linear homogeneous recurrences with constant coefficients which are equivalent to very simple forms?

V3-010088 | OEIS-A264354

Even nonsquare D values which admit proper solutions to the Pell equation x^2 - D*y^2 = +8.

The proper positive fundamental solution (x1(n), y1(n)) of the first class is given by (2*A261247(n), A261248(n)) for D(n) = a(n), n >= 1. If there are two classes the proper

positive fundamental solution (x2(n), y2(n)) for the second class is given by (A264357(n), A264386(n)) for D(n). If the fundamental solutions of the two classes coincide then there is only one class (the ambiguous case) for these D(n) values. It is conjectured that there are no more than two classes. For the computation of (x2(n), y2(n)) from (x1(n), -y1(n)) by application of the matrix M(n) for D(n) see a comment under A263012.

V3-010114 | OEIS-A265100

a(n) = 9*A005836(n) + 5, n >= 1.

Let C(m) denote the m-th Catalan number (A000108). Let == denote congruence and =!= its negation. _Vladimir Reshetnikov_ asked (see link) how many n exist such that C(n) == 1 (mod 6). It was pointed out by _Robert Israel_ that the only known n are in {1,3,31,255}. Since C(n) is odd if and only if n = 2^m - 1, for some m, _Emmanuel Vantieghem_ (see links) stated the stronger conjecture that C(2^n-1) == 0 (mod 3), for all n>8. This is the motivation for the following. If m is an integer such that the congruences C(m) =!= 0 (mod 3) and C(m-1) == 0 (mod 3) hold simultaneously, then we call m a "gap number." A sequence {m, m+1, ..., m+j-1} of consecutive numbers is called a "gap" (of order j), if C(m+i) =!= 0 (mod 3), for all i such that 0 <= i < j, and if C(m-1) == 0 (mod 3) (i.e., if m is a gap number) and C(m+j) == 0 (mod 3). (The sequence A265104 is conjectured to contain all possible gap numbers.) If C(n) == 0 (mod 3), then we say that n is "gap-avoiding." Conjecture 1: The sequence contains all possible block numbers. Conjecture 2: If m is a block number, then 3*m - 1 is a block number. Conjecture 3: If C(n) == 0 (mod 3), then C(3*n-1) == 0 (mod 3) or, what is the same thing, if n lies in a block, then 3*n - 1 lies in a block. Conjecture 4: Assuming that A265104 contains all possible gap numbers, let B(n) denote the block with block number a(n), n >= 1, so that B(n) = {a(n), a(n)+1, ..., A265104(n)-1}. The (flattened) sequence {B(1), B(2), ...} of blocks contains all numbers m such that the base 3 representations of m and m+1 both contain at least one 2 and is identical to A111018. Conjecture 5: C(n) == 0 (mod 3) if and only if the base 3 representations of n and n + 1 both contain at least one 2. [This conjecture has been proved by _Robert Israel_ (see link for the proof)]. Theorem 1: The following statements are equivalent to Vantieghem's conjecture stated above: (i) For all m>8, 2^m-1 is gap-avoiding; (ii) C(2^n-1) == 0 (mod 3) if and only if the base 3 representations of 2^n - 1 and 2^n both contain at least one 2. Proof: For (i), the statement obviously follows from the definitions, and (ii) follows from the proof of Conjecture 5. Conjecture: a(n) = A265104(n) - A085296(n).

V3-010116 | OEIS-A265159

Rectangular array A read by upward antidiagonals in which the entry in row n and column k is defined by A(n,k) = 5 + 9*A005836(2^(k - 1)*(2 n - 1)), n,k >= 1.

Conjecture 1: The array contains without duplication all possible "block numbers" defined in A265100. Conjecture 2: A(n,k) = (A055246(n)*3^k + 1)/2, so the array and A265100 are related to Cantor's ternary set. G.f. for row n (conjectured): f(n,x) = x*(A265100(n)-(A265100(n)+1)*x)/((1-x)*(1-3*x)).

V3-010123 | OEIS-A265251

Number of partitions of n such that there is exactly one part which occurs three times, while all other parts occur only once.

Conjecture: a(n) is also the difference between the number of parts in the distinct partitions of n and the number of distinct parts in the odd partitions of n (offset 0). For example, if n = 5, there are 5 parts in the distinct partitions of 5 (5, 41, 32) and 4 distinct parts in the odd partitions of 5 (namely, 5,3,1,1 in 5,311,11111) with difference 1. - _George Beck_, Apr 22 2017 George E. Andrews has kindly informed me that he has proved this conjecture and the result will be included in his article "Euler's Partition Identity and Two Problems of George Beck" which will appear in The Mathematics Student, 86, Nos. 1-2, January - June (2017). - _George Beck_, Apr 23 2017

V3-010124 | OEIS-A265262

The tree of hemitropic sequences read by rows, arising from an Erdős-Turán conjecture.

The tree of hemitropic sequences read by rows, arising from an Erdős-Turán conjecture. An [order 2 additive] basis of N is a subset A whose profile has no 0's. Erdős and Turán conjectured that the profile of a basis is always unbounded (see the Erdős and Turán link). The conjecture is, up till now,

still undecided. The tree below displays the infinite sequences [1, pA(2), ...], associated to the profiles pA = [1, 1, pA(2), ...] of all the subsets A of N to which 0 and 1 belong. Those are the so-called hemitropic sequences. The Erdős-Turán conjecture would not hold if (and only if) the tree contained an infinite bounded branch with no 0's.

V3-010131 | OEIS-A265385

Sequence defined by a(1)=a(2)=1 and a(n) = gray(a(n-1) + a(n-2)), with gray(m) = A003188(m).

Conjecture: The mean growth rate r(n) = (a(2n)/a(n))^(1/n) appears to converge exactly to 2, with the consecutive-terms ratio s(n) = a(n)/a(n-1) exhibiting relatively small (~1%) but persistent fluctuations around the mean value. This contrasts what one might first expect, that sequence's growth rate were similar to that of the Fibonacci sequence, i.e., the golden ratio, since gray(m) just permutes every block of numbers ranging from 2^k to 2^l-1, for any 0<k<l.

V3-010139 | OEIS-A265436

a(n) is the least m (1 <= m <= n) such that the set of pairs (x, y) of distinct terms from [m, n] can be ordered in such a way that the corresponding sums (x+y) and products (x*y) are monotonic.

Conjecture (derived from the assumed relationship with A035106): for n>5, if sqrt(4n+1) is an odd integer or sqrt(n+1) is an integer, then a(n) = a (n-1), otherwise a(n) = a(n-1)+1. - _Jean-François Alcover_, Dec 21 2015

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Bill McEachen_ and _Michel Marcus_, Dec 09 2015 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010140 | OEIS-A265437

Numbers n such that A265433(n) = 0 and n is not a multiple of 3.

Conjecture: if n > 4 is in the sequence, then A137269(n) > 0 due to primes with only digits 2, 3, 4.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Chai Wah Wu_, Dec 10 2015 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010141 | OEIS-A265481

Numbers k such that 9^k - 3^k - 1 is prime.

Conjectures: a(n) is not of the form 7*k+4 or 8*k. a(17) = 11071 mod 7 is 4, so the first half of the conjecture above is not true. - _Robert Price_, Sep 25 2019 a(23) = 78008 is divisible by 8, so the second half of the conjecture above is not true. - _Robert Price_, Sep 25 2019

V3-010189 | OEIS-A266277

Least positive integer x such that n + x^2 = y^3 + z^5 for some positive integers y and z, or 0 if no such x exists.

Conjecture: If {a,b,c} is among the multisets {2,2,p} (p is an odd prime or a product of primes congruent to 1 modulo 4) and {2,3,k} (k = 3,4,5), then for any integer m there are (infinitely many) triples (x,y,z) of positive integers such that m = x^a + y^b - z^c. This implies that a(n) > 0 for all n. Also, it includes the conjectures in A266152, A266212 and A266230 as special cases.

V3-010283 | OEIS-A266928

Number of steps needed to reach 1 or 2 where a step is x -> 3x+1 if x is odd, or x -> x/2p if x is even, 2p being the smallest semiprime dividing x.

Conjecture: all positive integers n not of the form 2^(2m+1) eventually reach 1.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Michel Lagneau_, Jan 06 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010284 | OEIS-A266949

a(n) is defined by Product_{i>=1} (1-a(i)*x^i) = Sum_{i>=0} möbius(i+1)*x^i.

Conjecture: All coefficients are positive and strictly increasing starting from 5th term.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Gevorg Hmayakyan_, Jan 06 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010285 | OEIS-A266952

Least prime p such that p-2 and 6n-p and 6n+2-p are also prime, or 0 if no such prime exists.

Up to 10^5, the only indices for which a(n)=0 are {0, 1, 16, 67, 86, 131, 151, 186, 191, 211, 226, 541, 701}. I conjecture that this list is finite, and probably complete. Is it a coincidence that all odd numbers > 1 in this list are primes? (See also A144094.) This seems equivalent to a conjecture Zwillinger made in 1978, see reference in LINKS.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _M. F. Hasler_, Jan 06 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010286 | OEIS-A266953

Least prime p such that p-2 and 6n-p and either 6n+2-p or 6n+4-p is also prime, or 0 if no such prime exists.

Up to 10^5, the only indices for which a(n)=0 are {0, 1, 16, 86, 131, 151, 186, 191, 211, 226, 541, 701}. (Only 2 and 67 require the alternative primality of 6n+4-p and have thus A266952(n)=0.) I conjecture that this list is finite, and probably complete. Is it a coincidence that all odd numbers in this list are primes?

V3-010320 | OEIS-A267120

Triangle of coefficients of Gaussian polynomials [2n+3,3]_q represented as finite sum of terms (1+q^2)^k*q^(g-k), where k = 0,1,...,g with g=3n.

Conjecture: More generally, the Gaussian polynomial [2*n+m+1-(m mod 2),m]_q = Sum_{k=0..g(m;n)} a(m;n,k)*(1+q^2)^k*q^(g(m;n)-k), for m >= 0, n >= 0, where g(m;n) = m*n if m is odd and (2*n+1)*m/2 if m is even, and the tabf array entries a(m;n,k) are the coefficients of the g.f. for the row n polynomials G(m;n,x) = (d^m/dt^m)G(m;n,t,x)/m!|_{t=0}, with G(m;n,t,x) = (1+t)*Product_{k=1..n+(m - m (mod 2))/2}(1 + t^2 + 2*t*T(k,x/2) (Chebyshev's T-polynomials). Hence a(m;n,k) = [x^k]G(m;n,x), for k=0..g(m;n). The present entry is the instance m = 3. (Thanks to _Wolfdieter Lang_ for clarifying the text on the general prescription of a(m;n,k).)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Stephen O'Sullivan_, Jan 10 2016 | 2026-10-24

V3-010333 | OEIS-A267182

Row 2 of the square array in A267181.

Colin Barker's conjectures below are true. Proof: A267181(ka,kb) = A267181(a,b) since both operations preserve the greatest common factor of the two coordinates, so A267181(2k,2) = A267181(k,1) = k for k > 1, the second conjecture. For odd coordinates, we have the forced chain (2k+1,2) -> (2,2k+1) -> (2,2k-1) -> ... -> (2,1) -> (1,2) -> (1,1) with k+3 operations, the third conjecture. The rest follow from combining these. V3-010378 | OEIS-A267414

Integers k such that there exist nonnegative integers x,y,z with k! = x^3 + y^3 + z^3.

Conjecture I: The natural density of this sequence is 1. Conjecture II: All integers > 13 are terms. The decomposition is not necessarily unique; for instance, 12! = 35^3 + 309^3 + 766^3 = 240^3 + 504^3 + 696^3. Deshouillers, Hennecart, & Landreau conjecture (the DHL conjecture) that the sequence of numbers that are a sum of at most three cubes has density 0.0999425... (see links). So roughly, if the DHL conjecture holds and if that density can be used as a probability that holds independently for candidates then we have the probability that 34! is the sum of at most 3 cubes to be 1 - (1-0.0999425)^660 ~= 1 - 6.6*10^-31. For larger k this probability doesn't tend to decrease. (End)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Altug Alkan_, Jan 14 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010379 | OEIS-A267435

Numbers n such that each reduced Collatz trajectory (mod p): (n, T(n), T(T(n)), ..., 4, 2, 1) / pZ, where the odd prime p is the number of iterations needed to reach 1, contains exactly the p-1 values {1, 2, 3, ..., p-1}.

This sequence provides a link with Artin's conjecture on primitive roots. Conjecture: the sequence is infinite (corollary of Artin's conjecture because the sequence contains the numbers 2^A001122(k) where A001122 are the primes with primitive root 2).

V3-010403 | OEIS-A267483

Triangle of coefficients of Gaussian polynomials [2n+3,2]_q represented as finite sum of terms (1+q^2)^k*q^(g-k), where k = 0,1,...,g with g=2n+1.

Conjecture: More generally, the Gaussian polynomial [2*n+m+1-(m mod 2),m]_q = Sum_{k=0..g(m;n)} a(m;n,k)*(1+q^2)^k*q^(g(m;n)-k), for m >= 0, n >= 0, where g(m;n) = m*n if m is odd and (2*n+1)*m/2 if m is even, and the tabf array entries a(m;n,k) are the coefficients of the g.f. for the row n polynomials G(m;n,x) = (d^m/dt^m)G(m;n,t,x)/m!|_{t=0}, with G(m;n,t,x) = (1+t)*Product_{k=1..n+(m - m (mod 2))/2}(1 + t^2 + 2*t*T(k,x/2) (Chebyshev's T-polynomials). Hence a(m;n,k) = [x^k]G(m;n,x), for k=0..g(m;n). The present entry is the instance m = 2. (Thanks to _Wolfdieter Lang_ for clarifying the text on the general prescription of a(m;n,k).)

V3-010448 | OEIS-A267794

a(n) = n-2-i, where i (0 <= i < n-2) is the largest number such that [a(n-2)-a(i); a(n-1)-a(i+1)] = [0; 0], or a(n) = 0 if no such i exists.

Maximal number of successive zeros in A181391 is 1, in this sequence 2. Conjecture : maximal number of successive zeros is k: a(0); ...; a(j)>0; a(j+1)=0; ...; a(j+k)=0; a(j+k+1)>0; ... The conjecture is true since (k+1)-th zero can occur only on the first occurrence of k successive zeros, by definition of such sequences. - _Andrey Zabolotskiy_, Oct 31 2016

V3-010457 | OEIS-A267824

Composite numbers n such that binomial(2n-1, n-1) == 1 (mod n^2).

Conjecture: n is a term if and only if n = A088164(i)^2 for some i >= 1 (cf. McIntosh, 1995, p. 385). - _Felix Fröhlich_, Jan 27 2016 The "if" part of the conjecture is true: see the McIntosh reference. - _Jonathan Sondow_, Jan 28 2016 The above conjecture implies that this sequence and A228562 are disjoint. - _Felix Fröhlich_, Jan 27 2016

V3-010458 | OEIS-A267826

Numbers not of the form w^3 + 2*x^3 + 3*y^3 + 4*z^3, where w, x, y and z are nonnegative integers.

Conjecture: The sequence has exactly 122 terms the last of which is a(122) = 41405. The conjecture implies that {P(v)+w^3+2*x^3+3*y^3+4*z^3: w,x,y,z = 0,1,2,...} = {0,1,2,...} whenever P(v) is among the polynomials a*v^3 (a = 1,5,6,7,9,10,12,15,18), b*v^4 (b = 1,2,3,5,6,12,18), c*v^5 (c = 1,2,5,12) and d*v^k (d = 5,12; k = 6,7). Moreover, it also implies that {8*t+w^3+2*x^3+3*y^3+4*z^3: t = 0,1; w,x,y,z = 0,1,2,...} = {0,1,2,...}. If a,b,c,d and m are positive integers with {m*t+a*w^3+b*x^3+c*y^3+d*z^3: t = 0,1; w,x,y,z = 0,1,2,...} = {0,1,2,...}, then we must have m = 8 and {a,b,c,d} = {1,2,3,4}.

V3-010499 | OEIS-A267969

Conjectured list of positive numbers k such that the Collatz-like map T: if x > 1 and x odd, x -> 5*x+1 and, if x even, x -> x/2, when started at k, eventually reaches a cycle that does not contain 1 (cf. A232711).

Conjectured list of positive numbers k such that the Collatz-like map T: if x > 1 and x odd, x -> 5*x+1 and, if x even, x -> x/2, when started at k, eventually reaches a cycle that does not contain 1 (cf. A232711). A companion to A232711 (which conjecturally lists the numbers whose trajectory reaches 1), and A267970 (which conjecturally lists the numbers whose trajectory diverges). This is conjectural in that there is no proof that the list is complete as far as it goes. Some of the terms in A267970 could belong to

A232711 or this sequence if the trajectory is extended far enough. - _N. J. A. Sloane_, Jan 23 2016

V3-010507 | OEIS-A268112

Numbers k for which the numerator of the k-th harmonic number H_k is divisible by the third power of a prime less than k.

It is a widely believed conjecture that there is no pair of an integer k and a prime p for which v_p(H_k) >= 4. If variations of this conjecture hold, then Krattenhaler and Rivoal (2007-2009) would be able to establish some formulas for their theory. See also A007757, A131657, and A131658. - _Petros Hadjicostas_, May 25 2020 Terms a(4) and a(5) are conjectural as possible existence of smaller terms is not eliminated. Carofiglio et al. (2025) computed some further terms (see links). - _Max Alekseyev_, Apr 01 2025

V3-010508 | OEIS-A268132

If a(n) is a square (and n > 1), then a(n+1) = a(n) + a(n-1), else a(n+1) is the smallest positive integer not occurring earlier.

Conjectured to be a permutation of the positive integers (which could be enforced by definition). In case there would occur a duplicate, it must be of the form a(n+1) = a(n) + a(n-1) and equal to an earlier term a(m+1) of the same form, where furthermore the predecessor a(m-1) also is of that form, since otherwise a(m+1) would be smaller than this a(n+1). This seems extremely unlikely to happen, and maybe provably impossible.

V3-010537 | OEIS-A268487

Numbers of equal electric charges for which the minimum-potential dislocation on a sphere has nonzero sum of position vectors.

Probably most of these terms are merely conjectural. - _N. J. A. Sloane_, Mar 31 2016 Numeric investigations were carried out by various authors for m = 1 to 204, and then for a number of selected cases (see references in the Wikipedia link). Among the studied cases, 312 is also known to belong to this sequence. All these cases have at most some type of C-symmetry (C_2,C_2v,C_s,C_3,C_3v). So far, 10 cases with no symmetry at all (C_1) were found, namely m = 61, 140, 149, 176, 179, 183, 186, 191, 194, 199. No simple algorithm to handle this open problem, nor a general formula, are known.

V3-010548 | OEIS-A268593

The largest of three distinct primes, a > b > c > 0, such that each of the following four numbers are also prime: a+b+c, a+b-c, a-b+c, a-b-c, regardless of sign.

Once found, the following three properties of these septets are observed without exception for "a" values up to prime(800), resulting in these conjectures: From the first conjecture it follows that no values for "a", "b" or "c" belong to A172256. The first three conjectures can be used to accelerate the search for prime septets. Further observations below are from accelerated searches.

V3-010565 | OEIS-A268867

Number of integers of the form m^2+1 between two consecutive pairs of primes of the same form.

Conjecture 1: the sequence is infinite. Conjecture 2: for n>1, the sequence sorted in ascending order with distinct values generates the set B = {b(k)} = {7, 17, 27, 37, ...} = {7 + 10*k}, k >= 0, and {a(n)}/qZ = B/qZ with q = 2^m, m >= 1, is a multiplicative group. However, this concept is based on a conjecture if it is impossible to prove the infinity character of a sequence. This requires, for the calculations, a large number of elements in the sequence.

V3-010603 | OEIS-A269304

a(n) = n + n/gpf(n) + 1, where gpf(n) is the greatest prime factor of n or 1 if n = 1.

It is conjectured that any two sequences generated with a(n)=a(n-1)+a(n-1)/gpf(a(n-1))+1 and any initial value >=1 will have a finite number of non-shared terms and an infinite number of shared terms after one initial shared term (see A270807). Example: For a(1)=314, the sequence generated is 314, 317, 319, 331, 333, 343, 393, 397, 399, 421, 423, 433, ...; for a(1)=97, the sequence generated is 97, 99, 109, 111, 115, 121, 133, 141, 145, 151, 153, 163, 165, 181, 183, 187, 199, 201, 205, 211, 213, 217, 225, 271, 273, 295, 301, 309, 313, 315, 361, 381, 385, 421, 423, 433, ...; these sequences have respectively 9 and 33 terms not shared with the other until both reach 421; the following terms of both sequences are identical.

V3-010605 | OEIS-A269346

Perfect cubes that are not the difference of two primes.

It is still an open conjecture that every even number is the difference of 2 primes. On the other hand, a computer test shows that all even cubes <= 10^21 can be written as the difference of 2 primes. The computer program generating the sequence needs an additional part to test for even cubes besides checking that for odd m^3, m^3+2 is composite. - _Chai Wah Wu_, Mar 03 2016

V3-010606 | OEIS-A269361

Lexicographically first injection of natural numbers beginning with a(1)=1 such that a(n)*a(n+1) is a fibbinary number (A003714), i.e., has no adjacent 1's in its base-2 representation.

The sequence is conjectured to be a permutation of A091072.

V3-010607 | OEIS-A269363

Lexicographically first injection of natural numbers beginning with a(1)=3 such that for all n >= 1, a(n)*a(n+1) is a fibbinary number (A003714), i.e., has no adjacent 1's in its base-2 representation.

The sequence is conjectured to be a permutation of A091067.

V3-010608 | OEIS-A269400

Number of ordered ways to write n as w^2 + x^2 + y^2 + z^2 with 6*w^2*x^2 + 12*x^2*y^2 + 52*y^2*z^2 + 27*z^2*w^2 a square, where w,x,y are nonnegative integers and z is a positive integer.

Conjecture: (i) a(n) > 0 for all n > 0, and a(n) = 1 only for n = 3, 15, 31, 39, 71, 79, 195, 311, 319, 403, 559, 591, 683, 719, 1031, 1439, 1643, 2519, 6879, 2^k, 2^(2k+1)*39 (k = 0,1,2,...). Also, any positive integer can be written as w^2 + x^2 + y^2 + z^2 with x a positive integer and w,y,z nonnegative integer such that 6*w^2*x^2 + 12*x^2*y^2 + 52*y^2*z^2 + 27*z^2*w^2 is a square. See also A268507, A271510, A271513, A271518, A271665, A271714, A271721, A271724, A271775, A271778 and A271824 for other conjectures refining Lagrange's four-square theorem.

V3-010615 | OEIS-A269427

a(1) = 1, a(n) counts m < n for which n == a(m) (mod m).

I conjecture that this sequence is unbounded. Consider the first k terms of this sequence, and let L be the floor of log(k). If we count the times that each number 1,2,...,2L appears among the first k terms of this sequence, it appears that these sums form a normal distribution centered at L, so that L appears approximately k/10 times among the first k terms of this sequence. (For instance, in the first k = 10000 terms of the sequence, L = log(10000) = 9 appears 1174 times, a maximal count among any value that appears at all.) Thus the sequence appears to be unbounded.

V3-010657 | OEIS-A269631

a(1) = 0; a(n+1) is the smallest integer not yet used that contains the number of decimal digits of a(n) as a substring.

Conjecture: a(n) is a permutation of the nonnegative integers. and the growth of percentage seems to support the conjecture.

V3-010662 | OEIS-A269657

Number of length-4 0..n arrays with no adjacent pair x,x+1 repeated.

I.e., a(n) = # {x in {0..n}^4 | x[1] != x[0]+1 or x[2] != x[0] or x[3] != x[1]}. The only possibility to have an adjacent x,x+1 pair repeated in a length-4 array is to have the array (x,x+1,x,x+1), with 0 <= x <= n-1 given the restriction on the domain of coefficients. This implies a(n) = (n+1)^4 - n and previously conjectured formulas. - _M. F. Hasler_, Feb 29 2020 Conjectures from _Colin Barker_, Jan 25 2019: (Start) a(n) = (n+1)^4 - n, cf. comment, confirming the above conjectured formulas. - _M. F. Hasler_, Feb 29 2020

V3-010749 | OEIS-A270226

a(n) is the number of terms in the n-th block of consecutive integers of A136119.

Conjecture: Partial average of the sequence converges to 1+sqrt(2). Proof of the conjecture: since A136119(n+1) - A136119(n) = A001030(n), the sequence (a(n+1)) is the fixed point of the substitution sigma: 2->32, 3->322. Here one uses that since sigma(a)=a, the length of the n-th block is coded by the n-th letter. Since the frequencies of 2 and 3 in this fixed point are respectively sqrt(2)/(1+sqrt(2)) and 1/(1+sqrt(2)), the conjecture follows. (Alternatively: (a(n+1)-2) is a Sturmian sequence with density sqrt(2)-1). - _Michel Dekking_, Jan 22 2017

V3-010787 | OEIS-A270803

Formal inverse of Thue-Morse sequence A010060.

Conjecture: a(n) = A151666(floor((n+1)/2)) for n > 0. - _Georg Fischer_, Nov 29 2022 Conjecture confirmed. See the attached file. The idea is to guess the automaton for this sequence (in base 2) and then verify that it satisfies the identities in the Gawron-Ulas paper. Next we make a (base 2) automaton for A151666. This is easy because it is just the numbers consisting only of 0 and 1 in base 4. Then finally we assert Fischer's identity and Walnut returns TRUE. - _Jeffrey Shallit_, Nov 30 2022

V3-010820 | OEIS-A271099

Number of ordered ways to write n as u^3 + v^3 + 2*x^3 + 2*y^3 + 3*z^3, where u, v, x, y and z are nonnegative integers with u <= v and x <= y.

Conjecture: (i) a(n) > 0 for all n = 0,1,2,..., and a(n) = 1 only for n = 0, 1, 10, 14, 15, 17, 22, 38, 39, 45, 47, 50, 52, 76, 102, 103, 188, 295, 366, 534. This conjecture is stronger than the classical Waring problem on sums of k-th powers. Concerning parts (i) and (ii) of the conjecture, we note that 1+1+2+2+3 = 9 = g(3), 1+1+2+2+3+3+7 = 19 = g(4) and 1+1+1+1+2+4+6+9+12 = 37 = g(5). We have verified that a(n) > 0 for all n = 0..10^6, and that part (ii) of the conjecture holds for n up to 10^5. Concerning part (iii) for k = 6, we conjecture that any natural number can be written as x(1)^6+x(2)^6+x(3)^6+x(4)^6+x(5)^6+3*x(6)^6+5*x(7)^6+6*x(8)^6+10*x(9)^6+18*x(10)^6+26*x(11)^6 with x(1),x(2),...,x(11) nonnegative integers. Note that 1+1+1+1+1+3+5+6+10+18+26 = 73 = g(6). - _Zhi-Wei Sun_, Mar 31 2016

V3-010821 | OEIS-A271106

Number of ordered ways to write n as x^6 + 3*y^3 + z^3 + w*(w+1)/2, where x and y are nonnegative integers, and z and w are positive integers.

Conjecture: a(n) > 0 for all n > 1, and a(n) = 1 only for n = 2, 3, 4, 6, 9, 13, 16, 20, 21, 24, 25, 44, 50, 51, 65, 84, 189, 290, 484, 616, 664, 680, 917, 1501, 1639, 3013. Based on our computation, we also formulate the following general conjecture. General Conjecture: Let T(w) = w*(w+1)/2. We have {P(x,y,z,w): x,y,z,w = 0,1,2,...} = {0,1,2,...} for any of the following polynomials P(x,y,z,w): x^3+y^3+c*z^3+T(w) (c = 2,3,4,6), x^3+y^3+c*z^3+2*T(w) (c = 2,3), x^3+b*y^3+3z^3+3*T(w) (b = 1,2), x^3+2y^3+3z^3+w(5w-1)/2, x^3+2y^3+3z^3+w(5w-3)/2, x^3+2y^3+c*z^3+T(w) (c = 2,3,4,5,6,7,12,20,21,34,35,40), x^3+2y^3+c*z^3+2*T(w) (c = 3,4,5,6,11), x^3+2y^3+c*z^3+w^2 (c = 3,4,5,6), x^3+2y^3+4z^3+w(3w-1)/2, x^3+2y^3+4z^3+w(3w+1)/2, x^3+2y^3+4z^3+w(2w-1), x^3+2y^3+6z^3+w(3w-1)/2, x^3+3y^3+c*z^3+T(w) (c = 3,4,5,6,10,11,13,15,16,18,20), x^3+3y^3+c*z^3+2*T(w) (c

= 5,6,11), x^3+4y^3+c*z^3+T(w) (c = 5,10,12,16), x^3+4y^3+5z^3+2*T(w), x^3+5y^3+10z^3+T(w), 2x^3+3y^3+c*z^3+T(w) (c = 4,6), 2x^3+4y^3+8z^3+T(w), x^4+y^3+3z^3+w(3w-1)/2, x^4+y^3+c*z^3+T(w) (c = 2,3,4,5,7,12,13), x^4+y^3+c*z^3+2*T(w) (c = 2,3,4,5), x^4+y^3+2z^3+w^2, x^4+y^3+4z^3+2w^2, x^4+2y^3+c*z^3+T(w) (c = 4,5,12), x^4+2y^3+3z^3+2*T(w), 2x^4+y^3+2z^3+w(3w-1)/2, 2x^4+y^3+c*z^3+T(w) (c = 1,2,3,4,5,6,10,11), 2x^4+y^3+c*z^3+2*T(w) (c = 2,3,4), 2x^4+2y^3+c*z^3+T(w) (c = 3,5), 3x^4+y^3+c*z^3+T(w) (c = 1,2,3,4,5,11), 3x^4+y^3+2z^3+2*T(w), 3x^4+y^3+2z^3+w^2, 3x^4+y^3+2z^3+w(3w-1)/2, 4x^4+y^3+c*z^3+T(w) (c = 2,3,4,6), 4x^4+y^3+2z^3+2*T(w), 5x^4+y^3+c*z^3+T(w) (c = 2,4), a*x^4+y^3+2z^3+T(w) (a = 6,20,28,40), 6x^4+y^3+2z^3+2*T(w), 6x^4+y^3+2z^3+w^2, a*x^4+y^3+3z^3+T(w) (a = 6,8,11), 8x^4+2y^3+4z^3+T(w), x^5+y^3+c*z^3+T(w) (c = 2,3,4), x^5+2y^3+c*z^3+T(w) (c = 3,6,8), 2x^5+y^3+4z^3+T(w), 3x^5+y^3+2z^3+T(w), 5x^5+y^3+c*z^3+T(w) (c = 2,4), x^6+y^3+3z^3+T(w), x^7+y^3+4z^3+T(w), x^4+2y^4+z^3+w^2, x^4+2y^4+2z^3+T(w), x^4+b*y^4+z^3+T(w) (b = 2,3,4), 2x^4+3y^4+z^3+T(w), a*x^5+y^4+z^3+T(w) (a = 1,2), x^5+2y^4+z^3+T(w). The polynomials listed in the general conjecture should exhaust all those polynomials P(x,y,z,w) = a*x^i+b*y^j+c*z^k+w*(s*w+/-t)/2 with {P(x,y,z,w): x,y,z,w = 0,1,2,...} = {0,1,2,...}, where a,b,c,s > 0, 0 <= t <= s, s == t (mod 2), i >= j >= k >= 3, a <= b if i = j, and b <= c if j = k.

V3-010823 | OEIS-A271169

Number of ordered ways to write n as s^5 + t^5 + 2*u^5 + 3*v^5 + 4*w^5 + 5*x^5 + 7*y^5 + 14*z^5, where s,t,u,v,w,x,y,z are nonnegative integers with s <= t.

Conjecture: a(n) > 0 for all n = 0,1,2,..., and a(n) = 1 only for n = 0, 1, 2602. For k = 2,3,4,... define s(k) as the smallest positive integer s such that {a(1)*x(1)^k+...+a(s)*x(s)^k: x(1),...,x(s) = 0,1,2,...} = {0,1,2,...} for some positive integers a(1), ..., a(s), and t(k) as the least positive integer t such that {a(1)*x(1)^k+...+a(t)*x(t)^k: x(1),...,x(t) = 0,1,2,...} = {0,1,2,...} for some positive integers a(1), ..., a(t) with a(1)+...+a(t) = g(k), where g(.) is given by A002804. Then s(k) <= t(k) <= g(k). Part (iii) of the conjecture in A271099 implies that t(k) <= 2k-1 for k > 2. It is easy to see that s(2) = t(2) = 4. Our computation suggests that s(3) = t(3) = 5, s(4) = t(4) = 7, s(5) = t(5) = 8 (which is smaller than 2*5-1), and s(6) = t(6) = 10. We conjecture that s(k) = t(k) for any integer k > 1, and that each natural number can be written as x(1)^6+x(2)^6+x(3)^6+2*x(4)^6+3*x(5)^6+5*x(6)^6+6*x(7)^6+10*x(8)^6+18*x(9)^6+26*x(10)^6, where x(1),x(2),...,x(10) are nonnegative integers. Note that 1+1+1+2+3+5+6+10+18+26 = 73 = g(6). We also conjecture that any natural number can be written as s^5+t^5+2*u^5+3*v^5+4*w^5+6*x^5+8*y^5+12*z^5, with s,t,u,v,w,x,y,z nonnegative integers. Note that 1+1+2+3+4+6+8+12 = 37 = g(5). - _Zhi-Wei Sun_, Apr 04 2016

V3-010832 | OEIS-A271325

Number of ordered ways to write n as x^3 + y^2 + z*(3z+1), where x, y and z are integers with x positive and y nonnegative.

Based on our computation, we propose the following general conjecture (which extends the conjectures in A262813 and A270469). Conjecture: Let T(x) = x*(x+1)/2 and pen(x) = x*(3x+1)/2. Every natural number can be written as P(x,y,z) with x a nonnegative integer and y and z integers, where P(x,y,z) is any of the following cubic polynomials: x^3+T(y)+z^2, a*x^3+T(y)+pen(z) (a = 1,2,3,4), x^3+T(y)+z*(5z+1)/2, x^3+T(y)+z*(3z+r) (r = 1,2), x^3+T(y)+z*(7z+3)/2, x^3+T(y)+z*(9z+j)/2 (j = 5,7), x^3+T(y)+z*(5z+r) (r = 2,3), x^3+T(y)+2z*(3z+r) (r = 1,2), x^3+T(y)+z*(6z+5), x^3+T(y)+z*(13z+j)/2 (j = 3,7,9), x^3+T(y)+z*(7z+k) (k = 2,6), a*x^3+y^2+pen(z) (a = 1,2,3,4), x^3+y^2+z*(5z+3)/2, x^3+y^2+2*pen(z), x^3+2*T(y)+pen(z), x^3+2*T(y)+z(5z+j)/2 (j = 1,3), a*x^3+2*T(y)+z*(3z+2) (a = 1,2,3), x^3+2*T(y)+z*(7z+3)/2, x^3+4*T(y)+pen(z), x^3+2y^2+pen(z), x^3+pen(y)+c*pen(z) (c = 1,2,3,4), x^3+b*pen(y)+z*(5z+j)/2 (b = 1,2; j = 1,3), x^3+pen(y)+z*(7z+k)/2 (k = 1,3,5), x^3+pen(y)+z*(4z+j) (j = 1,3), x^3+pen(y)+z*(9z+5)/2, a*x^3+pen(y)+z*(9z+r)/2 (a = 1,2; r = 1,7), x^3+pen(y)+z*(5z+r) (r = 1,2,3,4), a*x^3+pen(y)+z*(11z+9)/2 (a = 1,2), x^3+pen(y)+2z*(3z+2),x^3+pen(y)+z*(13z+11)/2, x^3+pen(y)+z*(7z+k) (k = 4,5,6), x^3+pen(y)+3z*(5z+3)/2, x^3+pen(y)+z*(15z+11)/2, x^3+pen(y)+z*(8z+7), x^3+pen(y)+z*(11z+7), x^3+2*pen(y)+z*(7z+j)/2 (j = 1,5), x^3+2*pen(y)+3*pen(z), x^3+2*pen(y)+z*(4z+1), x^3+2*pen(y)+z*(7z+2), x^3+y*(5y+j)/2+z*(7z+k)/2 (j = 1,3; k = 3,5), x^3+y*(5y+3)/2+z*(9z+7)/2, x^3+y*(3y+2)+z*(4z+1), x^3+y*(3y+2)+z*(5z+1)/2, x^3+y*(7y+3)/2+z*(7z+5)/2, 2x^3+T(y)+z*(5z+3)/2, 2x^3+T(y)+z*(3z+r) (r = 1,2), 2x^3+T(y)+z*(5z+4), 2x^3+2*T(y)+z*(5z+3)/2, 2x^3+3*T(y)+pen(z), 2x^3+y^2+2*pen(z), 2x^3+pen(y)+pen(z), a*x^3+pen(y)+3*pen(z) (a = 2,3,4), a*x^3+pen(y)+z*(7z+5)/2 (a = 2,3,4), 2x^3+pen(y)+z*(5z+k) (k = 1,3), 2x^3+y*(5y+3)/2+z*(7z+5)/2, 2x^3+2*pen(y)+z*(3z+2), 2x^3+2*pen(y)+z*(7z+5)/2, 2x^3+y*(3y+2)+z*(4z+3), 3x^3+pen(y)+z*(7z+3)/2, 4x^3+y^2+z*(5z+1)/2, 4x^3+pen(y)+z*(4z+3). The listed ternary polynomials in the conjecture should exhaust all those P(x,y,z) = a*x^3+y*(s*y+t)/2+z*(u*z+v)/2 with a,s,u > 0, 0 <= t <= s, 0 <= v <= u, s == t (mod 2), u == v (mod 2), and (s-2t)*(u-2v) nonzero, such that any natural number can be written as P(x,y,z) with x a nonnegative integer and y and z integers. Note that those numbers y*(2y+1) with y integral are just triangular numbers. Conjecture verified for all polynomials up to 10^11. - _Mauro Fiorentini_, Aug 03 2023 See also A271106 for another general conjecture on universal sums.

V3-010841 | OEIS-A271513

Number of ordered ways to write n as w^2 + x^2 + y^2 + z^2 with 3*x^2 + 4*y^2 + 9*z^2 a square, where w, x, y and z are nonnegative integers.

Conjecture: (i) a(n) > 0 for all n = 0,1,2,..., and a(n) = 1 only for n = 0, 3, 11, 23, 43, 47, 67, 83, 107, 155, 323, 683, 803, 4^k*m (k = 0,1,2,... and m = 22, 38). [Conjecture verified for all natural numbers up to 10^9. - _Mauro Fiorentini_, Jul 04 2024] (ii) Any natural number can be written as w^2 + x^2 + y^2 + z^2 with x, y, z integers and a*x^2 + b*y^2 + c*z^2 a square, whenever (a,b,c) is among the following triples: (1,3,12), (1,3,18), (1,3,21), (1,3,60), (1,5,15), (1,8,24), (1,12,15), (1,24,56), (1,24,72), (1,48,72), (1,48,168), (1,120,180), (1,192,288), (1,280,560), (3,9,13), (4,5,12), (4,5,60), (4,9,60), (4,12,21), (4,12,45), (4,12,69), (4,12,93), (4,12,237), (4,21,24), (4,21,36), (4,21,504), (4,24,93), (4,28,77), (4,45,120), (4,45,540), (4,45,600), (5,36,40), (7,9,126), (7,9,588), (8,16,73), (8,16,97), (8,49,112), (9,13,27), (9,16,24), (9,19,36), (9,21,91), (9,24,232), (9,28,63), (9,40,45), (9,40,56), (9,40,120), (9,45,115),(9,45,235), (12,13,24), (12,13,36), (12,36,37), (12,36,133), (13,36,72), (13,36,108), (15,24,25), (15,49,105), (16,17,48), (16,20,45), (16,21,84), (16,33,72), (16,33,176), (16,45,180), (16,48,57), (16,48,105), (16,48,233), (16,48,249), (19,45,57), (19,45,180), (21,25,35), (21,25,75), (21,28,36), (21,28,60), (21,43,105), (21,100,105),(24,25,72), (24,25,120), (24,48,97), (24,81,184), (24,120,145), (25,36,75), (25,40,56), (25,45,51), (25,45,99), (25,48,96), (25,48,144), (25,54,90), (25,75,81), (25,80,184), (25,96,120), (25,200,216), (28,33,36), (28,36,77), (28,72,189), (32,64,73), (33,36,220), (33,48,144), (33,72,256), (33,88,144), (36,45,100), (36,45,172), (37,81,243), (40,81,120), (40,81,240), (41,64,256), (45,48,76), (48,144,177), (49,56,64), (49,63,72), (55,141,165), (57,64,192), (60,105,196), (64,65,160), (72,73,144), (81,160,240), (85,140,196), (105,112,144), (112,144,153), (136,144,153), (144,145,240), (144,160,225),(148,189,252), (175,189,225). [Conjecture verified for all triples and all natural numbers up to 10^9. - _Mauro Fiorentini_, Jul 04 2024] This conjecture is stronger than Lagrange's four-square theorem. Moreover, there are many other suitable triples (a,b,c) for our purpose not listed in part (ii) of the conjecture. If a, b and c are positive integers such that any natural number can be written as w^2 + x^2 + y^2 + z^2 with x, y, z integers and

a*x^2 + b*y^2 + c*z^2 a square, then one of a+b+c, 4*a+b+c, a+4*b+c and a+b+4*c must be a square since 2^2 + 1^2 + 1^2 + 1^2 is the unique way to express 7 as a sum of four squares. See also A271510 and A271518 for related conjectures.

V3-010857 | OEIS-A271721

Number of ordered ways to write n as x^2 + y^2 + z^2 + w^2 with x >= y >= z >= 0, x > 0 and w >= z such that (x-y)*(w-z) is a square.

Conjecture: (i) a(n) > 0 for all n > 0, and a(n) = 1 only for n = 1, 3, 5, 11, 15, 23, 35, 95, 4^k*190 (k = 0,1,2,...). This is stronger than Lagrange's four-square theorem. Note that for k = 2 or 3, any natural number n can be written as w^2 + x^2 + y^2 + z^2 with w,x,y,z nonnegative integers and (x-y)*(w-k*z) = 0, for, if n cannot be represented by x^2 + y^2 + 2*z^2 then it has the form 4^k*(16*m+14) (k,m = 0,1,2,...) and hence it can be represented by x^2 + y^2 + (k^2+1)*z^2. It is known that natural numbers not represented by x^2 + y^2 + 5*z^2 have the form 4^k*(8*m+3), and that positive even numbers not represented by x^2 + y^2 + 10*z^2 have the form 4^k*(16*m+6) (as conjectured by S. Ramanujan and proved by L. E. Dickson). See also A271510, A271513, A271518,

A271644, A271714 and A271724 for other conjectures refining Lagrange's theorem.

V3-010865 | OEIS-A271834

a(n) = 2^n - Sum_{m=0..n} binomial(n/gcd(n,m), m/gcd(n,m)) = 2^n - A082906.

Compared to A082906, this sequence shows better the drop from 2^n upon replacing every binomial(n,m) in the Newton's expansion of (1+1)^n by the 'reduced' binomial(n/gcd(n,m), m/gcd(n,m)). For n > 1, a(n) is zero if and only if n is prime (no reduction, no drop). The ratio r(n) = a(n)/2^n is always smaller than 1 and presents considerable excursions. For composite n up to 5000, the minimum of 0.01471... occurs for n = 4489, and the maximum of 0.80849... occurs for n = 2310. This apparently large relative difference is actually surprisingly small: on log_2 scale it amounts to just about 5.78; a tiny fraction compared to the full scale, given by the values of n for the extrema. This insight suggests the following conjecture: there exists an average ratio r, defined as r = lim_{n->infinity} Sum_{m=1..n} r(m)/n. Its value appears to be approximately 0.3915+-0.0010, which can be interpreted as the average drop in a binomial value upon the 'reduction' of its arguments.

V3-010870 | OEIS-A271910

Array read by antidiagonals: T(n,k) = number of ways to choose 3 distinct points from an n X k rectangular grid so that they form an isosceles triangle.

It appears that for each n >= 2, there is a number K(n) such that row n satisfies the recurrence a(k) = 2*a(k-1)-2*a(k-3)+a(k-4) for k >= K(n). This is based on the fact that the conjectured generating functions for rows 2, 3, 4, 5 have the same denominator, and on _Colin Barker_'s conjectured recurrence for A271911. K(n) is determined by the degree of the numerator of the g.f. Above conjecture about the recurrence is true for K(n) = (n-1)^2+4 if n is even and K(n) = (n-1)^2+3 if n is odd and not true for smaller K(n). See paper in links. - _Chai Wah Wu_, May 07 2016

V3-010889 | OEIS-A272198

The p-defect p - N(p) of the congruence y^2 == x^3 + 1 (mod p) for primes p, where N(p) is the number of solutions given by A272197(n).

If prime(n) == 1 (mod 3) = A002476(m) (for a unique m = m(n)) then prime(n) = A(m)^2 + 3*B(m)^2 with A(m) = A001479(m+1) and B(m) = A001480(m+1), m >= 1. In this case (4*prime(n) - a(n)^2)/12, seems to be a square, q(m)^2. In fact is seems that (the positive) q(m) = B(m). This is true at least for the first 80 primes 1 (mod 3), i.e. for such primes <= 997. (In the Silverman reference, in hint c) for Exercise 4.5, on p. 405, a more complicated way is suggested: 4*p is decomposed there non-uniquely instead of p uniquely.) If this conjecture is true then a(n) = 2*(+/-sqrt(prime(n) - 3*B(m)^2)) = +- 2*A(m) for prime(n) = A002476(m). This leads to a bisection of the primes 1 (mod 3) into two types: type I if the + sign applies, and type II for the - sign. Primes of type I are given in A272200: 13, 19, 43, 61, 97, ... and those of type II in A272201: 7, 31, 37, 67, 73, ... The above given conjecture for primes 1 (mod 3) is true because Mordell proved the Ramanujan conjecture on the expansion coefficients of eta^4(6*z), and with the present a(n) the result of Ramanujan follows. See the references and a comment on A000727.

V3-010890 | OEIS-A272203

P-defects p - N(p) of the congruence y^2 == x^3 - 1 (mod p) for primes p, where N(p) is the number of solutions given by A272202(n).

If prime(n) == 1 (mod 3) = A002476(m) (for a unique m = m(n)) then prime(n) = A(m)^2 + 3*B(m)^2 with A(m) = A001479(m+1) and B(m) = A001480(m+1), m >= 1. In this case (4*prime(n) - a(n)^2)/12, seems to be a square, q(m)^2. In fact is seems that (the positive) q(m) = B(m). If this conjecture is true then a(n) = 2*(+-sqrt(prime(n) - 3*B(m)^2)) = +- 2*A(m) for prime(n) = A002476(m). This leads to a bisection of the primes 1 (mod 3) into two types: type I if the + sign applies, and type II for the - sign. Primes of type I are given in A272204: 7,13,31,61,67, ... and those of type II in A272205: 19,37,43,73,103, ... The above given conjecture for primes 1 (mod 3) is expected to be true by analogy to the case A272198 where only the signs differ.

V3-010955 | OEIS-A273110

Number of ordered ways to write n as x^2 + y^2 + z^2 + w^2 with (x+4*y+4*z)^2 + (9*x+3*y+3*z)^2 a square, where x,y,z,w are nonnegative integers with y > 0 and y >= z <= w.

Conjecture: (i) a(n) > 0 for all n > 0, and a(n) = 1 only for n = 4^k*m (k = 0,1,2,... and m = 1, 7, 23, 31, 39, 47, 55, 71, 79, 119, 151, 191, 311, 671). See also A271714, A273107, A273108 and A273134 for similar conjectures related to Pythagorean triples. For more conjectural refinements of Lagrange's four-square theorem, one may consult arXiv:1604.06723.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, May 15 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010956 | OEIS-A273134

Number of ordered ways to write n as x^2 + y^2 + z^2 + w^2 with (x+8*y+8*z+15*w)^2+(6*(x+y+z+w))^2 a square, where x,y,z,w are nonnegative integers with y < z.

Conjecture: (i) a(n) > 0 for all n > 0, and a(n) = 1 only for n = 3, 7, 11, 15, 21, 23, 35, 39, 71, 95, 4^k*m (k = 0,1,2,... and m = 1, 2, 5, 6, 10, 14, 29, 30, 46, 62, 94, 110, 142, 190, 238, 334, 446). Part (i) of this conjecture implies that any positive integer can be written as x^2 + y^2 + z^2 + w^2 with x,y,z,w nonnegative integers such that x+8*y+8*z+15*w and 6*(x+y+z+w) are the two legs of a right triangle with positive integer sides. If a nonnegative integer n is not of the form 4^k*(16m+14) (k,m = 0,1,2,...), then n can be written as w^2+x^2+y^2+z^2 with w = x and hence (x+8y+8z+15w)^2 + (6(x+y+z+w))^2 = (8(2x+y+z))^2 + (6(2x+y+z))^2 = (10(2x+y+z))^2. Similar remarks apply to part (ii) of the conjecture. See also A271714, A273107, A273108 and A273110 for similar conjectures related to Pythagorean triples. For more conjectural refinements of Lagrange's four-square theorem, one may consult arXiv:1604.06723.

V3-010962 | OEIS-A273278

Number of ordered ways to write n as x^2 + y^2 + z^2 + w^2 with x,y,z,w nonnegative integers such that x^2*y^2 + 3*y^2*z^2 + 2*z^2*w^2 is a square.

Conjecture: a(n) > 0 for all n = 0,1,2,..., and a(n) = 1 only for n = 0, 4^k*m (k = 0,1,2,... and m = 7, 39, 87, 183, 231, 807, 879, 959, 1479, 2391, 2519, 2759, 4359, 10887). See part (ii) of the conjecture in A269400 for similar conjectures. For more conjectural refinements of Lagrange's four-square theorem, one may consult arXiv:1604.06723.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, May 18 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-010963 | OEIS-A273294

Least nonnegative integer m such that there are nonnegative integers x,y,z,w for which x^2 + y^2 + z^2 + w^2 = n and x + 3*y + 5*z = m^2.

Clearly, a(n) = 0 if n is a square. Part (i) of the conjecture in A271518 implies that a(n) always exists. For more conjectural refinements of Lagrange's four-square theorem, one may consult arXiv:1604.06723.

V3-011020 | OEIS-A273724

Place n equally-spaced points around a circle, labeled 0,1,2,...,n-1. For each i = 0..n-1 such that 3i != i mod n, draw an (undirected) chord from i to (3i mod n). Then a(n) is the total number of distinct chords.

a(n) = n-1 if n>0 is odd, n-2 if n == +-2 (mod 8), n-3 if n == 4 (mod 8), and n-5 if n == 0 (mod 8). These formulas are easily established by observing that the chord at i is missing if 2i == 0 mod n, and the chords starting at i and at 3i coincide if 8i == 0 mod n. The formulas then imply that the g.f. is 4+x^2/(1-x)^2-(4+x^2+2*x^4+x^6)/(1-x^8), which can be rewritten as (5*x^63*x^5+2*x^4+3*x^2-x+2)*x^3/((1-x)*(1-x^8)). (This g.f. was conjectured by _Colin Barker_.) - _Brooke Logan_ and _N. J. A. Sloane_, Jun 23 2016

V3-011051 | OEIS-A273915

Number of ordered ways to write n as w^5 + x^2 + y^2 + z^2, where w,x,y,z are nonnegative integers with x <= y <= z.

Let c be 1 or 4. Then any nonnegative integer n can be written as c*w^5 + x^2 + y^2 + z^2 with w,x,y,z nonnegative integers. We now prove this by induction on n. For n < 2^(10) this can be verified directly via a computer. If 2^(10) divides n, then by the induction hypothesis we can write n/2^(10) as c*w^5 + x^2 + y^2 + z^2 with w,x,y,z, nonnegative integers, and hence n = c*(2^2*w)^5 + (2^5*x)^2 + (2^5*y)^2 + (2^5*z)^2. If n is not of the form 4^k*(8m+7) with k and m nonnegative integers, then n is the sum of three squares and hence n = c*0^5 + x^2 + y^2 + z^2 for some integers x,y,z. When n = 4^k*(8m+7) > 2^(10) with k < 5, it is easy to see that n - c*1^5 or n - c*2^5 is the sum of three squares. For some conjectural refinements of Lagrange's four-square theorem, one may consult the author's preprint arXiv:1604.06723

V3-011081 | OEIS-A274260

Forbidden residues of the greedy prime offset sequence.

The greedy prime offset sequence, A135311, is the closepacked integer sequence, starting with 0, such that for no prime p does the sequence form a complete system of residues modulo p. Instead, at least one residue must be missing for p, this is the (conjectured to be unique) "forbidden residue" for p. The first few terms of the greedy sequence are 0, 2, 6, 8, 12, 18. For the first three primes: 2, 3, 5, the forbidden residues are, respectively: 1, 1, 4. More generally, a(n) gives the forbidden residue for the n-th prime number. Every prime, it appears, has a unique forbidden residue, but this is unproven as far as I know. If this is true then every prime has an "exhaustion number" which is the number of terms of the greedy sequence needed to exhaust all the other residues and determine which one is forbidden; see A274261.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _R. Michael Perry_, Jun 16 2016 | 2026-10-24

V3-011125 | OEIS-A275206

Expansion of (A(x)^2 - A(x^2))/2 where A(x) = A000108(x) - 1.

Substituting A(x) = Sum_{n >= 1} c(n)*x^n in the above expression, we get (after some algebra) that a(n) = (-2*c(n) + c(n+1) - [(n mod 2) == 0]*c(n/2))/2 for n >= 1. It is then easy to prove that a(n) = 2*A050182(n-2) = (1/n)*(binomial(2*n, n-2) - [(n mod 2) == 0]*binomial(n, (n/2) - 1)) for n >= 2, thus proving the conjecture below. (End) Conjecture: a(n) = 2*A050182(n-2) for n >= 2.

V3-011129 | OEIS-A275288

Least k such that there exists a sequence b_1 < b_2 < ... < b_t = k that includes n and has a reciprocal sum of 1.

Conjectures: Conjecture (confirmed for all n <= 40000): for all n > 1, the lower bound given above is tight, i.e., a(n) = m*P where m and P are as defined above. (See Example section.) (End)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Peter Kagey_, Aug 18 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011130 | OEIS-A275297

Number of ordered ways to write n as x^2 + y^2 + z^2 + w^3 with x + 2*y a square, where x,y,z,w are nonnegative integers with z >= w.

Conjecture: a(n) > 0 for all n = 0,1,2,..., and a(n) = 1 only for n = 0, 3, 7, 8, 11, 12, 15, 23, 24, 32, 39, 47, 71, 103, 120, 136, 159, 176, 183, 218, 359, 463. Compare this conjecture with Conjecture 5.1 of the author's preprint arXiv:1604.06723. See also A275298 and A275299 for similar conjectures. Let c be 1 or 2. By the conjecture in A272979, any n = 0,1,2,... can be written as x^2 + 2*y^2 + z^3 + 2*c^2*w^4 with x,y,z,w nonnegative integers, and hence n = x^2 + (y+c*w^2)^2 + (y-c*w^2)^2 + z^3 with (y+c*w^2)-(y-c*w^2) = 2*c*w^2. If n > 0 is not among the 174 terms in the b-file of A275169, then the conjecture in A275169 implies that n can be written as x^2 + y^2 + z^2 + w^3 with x - y = 0^2, where x,y,z,w are nonnegative integers. If n is among the 174 terms in the b-file of A275169, then we may use a computer to verify that n can be written as x^2 + y^2 + z^2 + w^3 with c*(x-y) a square, where x,y,z,w are nonnegative integers.

V3-011156 | OEIS-A275492

Number of primitive weird numbers (A002975) between 10^n and 10^(n+1).

It is not known unconditionally whether there are infinitely many primitive weird numbers (PWN, A002975), although numerical data provides strong evidence: even the number of weird numbers of the form 2^k*p*q (A258882, A258333) seems to increase rapidly as k increases. Melfi has shown that Cramer's conjecture implies the infiniteness of PWN.

V3-011183 | OEIS-A275974

Partial sums of the Jeffreys binary sequence A275973.

The ratio d(n) = a(n)/n, while obviously bounded, has no limit. Rather, it kind of 'oscillates', at an exponentially decreasing rate, between about 1/3 and 2/3. As mentioned by Jeffreys, the values of liminf and limsup of the set {d(n)} are 1/3 and 2/3, respectively. A proof of this fact by elementary means is relatively easy, for example, using the first formula below, but the following statement is a conjecture: Any real value c in the interval [1/3, 2/3] is an accumulation point of {d(n)}.

V3-011191 | OEIS-A276091

Numbers obtained by reinterpreting base-2 representation of n in A001563-base (A276326): a(n) = Sum_{k>=0} A030308(n,k)*A001563(k+1).

Conjectured also to give all numbers n for which A255411(n) = A276340(n) (thus zeros of A276339).

V3-011196 | OEIS-A276136

Numbers m > 1 such that the largest odd divisors of m-1, m, and m+1 are prime.

Conjecture: this sequence is finite.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Juri-Stepan Gerasimov_, Aug 22 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011197 | OEIS-A276140

Replacing every "mixed pair" of integers with the absolute difference of the said pair of integers rebuilds the sequence itself (see "Comments" for the definition of a "mixed pair").

To elaborate reasons for the above conjecture about nonappearance, in the current b-file (8002 terms), only two terms, a(7) = 3 and a(11) = 5, have a value less than half their index. The plot2 link shows an apparently growing propensity for numbers not to appear later than the matching index. - _Peter Munn_, Aug 12 2023

V3-011234 | OEIS-A276710

Composite numbers m such that Product_{k=0..m} binomial(m,k) is divisible by m^(m-1).

Conjecture, tested so far up to m = 3828: "When m belongs to this list, Product_{k=0..m} binomial(m,k) is divisible also by m^m". Since this is impossible for prime m (see, e.g., A109874), the conjecture is equivalent to the statement "m is prime if and only if Product_{k=0..m} binomial(m,k) is divisible by m^(m-1) but not by m^m". This conjecture has been proved, see corollary 3 in PDF link below.

V3-011235 | OEIS-A276711

Number of primes p <= n such that n - p is a perfect power (including 0 and 1).

Conjecture: For n > 1, we have a(n) > 0 except for n = 11^6 = 1771561. In other words, any integer n > 1 other than 11^6 can be written as p + x^k, where p is a prime, x is a nonnegative integer and k is an integer greater than one. Moreover, any integer n > 5 not among 8, 24, 1549, 1771561 can be written as p + x^k, where p is a prime, and x and k are integers greater than one. This has been verified for n up to 10^10. On the author's request Prof. Qing-Hu Hou at Tianjin Univ. verified it for n up to 6*10^9, and then the author used Hou's program to check the conjecture for n from 6*10^9 to 10^10. The author has also finished the verification of the conjecture for squares not exceeding 10^14 and sixth powers not exceeding 10^18, for example, 991^6 - 230^5 is a prime. - _Zhi-Wei Sun_, Sep 22 2016

V3-011256 | OEIS-A277109

Starting from 2^n+1, the length of the longest sequence of consecutive numbers which all take the same number of steps to reach 1 in the Collatz (or '3x+1') problem.

Conjecture: If a(n) = 2^k - 1 for some k > 1, then a(n-1) = 2^(k-1) - 1. Conjecture holds for n <= 1812. The conjecture is true. Let the lengths of the Collatz runs equal q for all numbers 2^n + 1, 2^n + 2, 2^n + 3, 2^n + 4, ..., 2^n + 2^k - 2, 2^n + 2^k - 1. Then dividing the 2^(k-1) - 1 even numbers by two gives rise to the sequence 2^(n-1) + 1, 2^(n-1) + 2, ..., 2^(n-1) + 2^(k-1) - 1 of numbers for which the lengths of the Collatz runs equals q-1. Furthermore, let the length of the Collatz run of 2^n + 2^k be r != q then the length of the Collatz run of 2^(n-1) + 2^(k-1) is r-1 != q-1, i.e., a(n-1) = 2^(k-1) - 1. Conjecture: Let a(k), ..., a(k+m), m >= 0, be a subsequence of this sequence such that a(k)=a(k+m+1)=1 and a(k+i) > 1, 1 <= i <= m. Then the lengths of the Collatz runs of a(k+i), 0 <= i <= m, increase by 1. In addition, there is an initial segment of increasing numbers a(k), ..., a(k+j), for some 0 <= j <= m, in each such subsequence having the form 2^i - 1, 0 < i <= j. (End)

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011257 | OEIS-A277120

Number of branching factorizations of n.

The value of a(n) depends only on the prime signature of n. In other words, for all i, j >= 1, it holds that A101296(i) = A101296(j) => a(i) = a(j). Moreover, it seems that the converse proposition also holds, that for all i, j >= 1, a(i) = a(j) => A101296(i) = A101296(j), i.e., for each distinct prime signature there exists a distinct value of a(n). This has been empirically checked up to the first 21001 prime signatures in A025487 (see A366884), and can be proved if one can show that the latter sequence (equally: A366377) is injective. If this conjecture holds, it would imply an unlimited number of statements like those given in the previous comment (see the formula section of A101296).

V3-011266 | OEIS-A277201

Primes of the form (p^4 + 1)/2, where p is prime.

Conjecture: the sequence consists of the numbers k such that tau(2k) = 4 and tau(2k-1) = 5. tau(82) = 4 and tau(81) = 5, 82/2 = 41 = a(1). tau(626) = 4 and tau(625) = 5, 626/2 = 313 = a(2). tau(2402) = 4 and tau(2401) = 5, 2402/2 = 1201 = a(3). The conjecture was checked for 10^9 consecutive integers. The above conjecture is true: since tau(2k-1) = 5, 2k-1 must be the 4th power of some prime p, i.e., k = (p^4 + 1)/2 (so p is odd, so p^4 == 1 (mod 16), so k is odd), and since tau(2k) = 4, 2k must be the product of two distinct primes, so k is an odd prime. Thus, the set of numbers k such that tau(2k) = 4 and tau(2k-1) = 5 is the set of primes of the form (p^4 + 1)/2, where p is prime. - _Jon E. Schoenfield_, Mar 17 2019

V3-011270 | OEIS-A277272

a(n+1) is the smallest number not already in the sequence whose sum of prime factors (with repetition) shares a factor with the sum of the prime factors of a(n); a(1)=2.

Inspired by A064413 (the EKG sequence). Conjecture: The sequence is a permutation of the natural numbers >1, in which composite terms appear once only (in irregular fashion) and the primes arise in their natural order. Immediately following the appearance of any prime p>3 the next term is q*(2^r) where q is the largest prime less than p, and r is the unique integer such that p=q+(2*r). The above conjecture fails at a(95)=23, which appears before a(162)=19. (Also, the term appearing immediately after 37 is 218=2*109; the term immediately after 97 is 1335=3*5*89.) - _Jon E. Schoenfield_, Nov 05 2016

V3-011273 | OEIS-A277338

Reverse and Add! sequence starting with 295.

295 is conjectured to be the second smallest initial term which does not lead to a palindrome. Also, 196 is possibly the smallest initial term which does not lead to a palindrome. a(0) = 196 is described in A006960.

V3-011283 | OEIS-A277581

Goldbach's problem extended to squares of nonnegative differences of primes: smallest integer >= ((A112823(n) - A234345(n))^2)/n for n >= 2.

Conjecture: 1 <= a(n) <= m for all n, where m is largest value of a(n), i.e., the sequence of records in a(n) {1, 5, 15, 20, ..., m} is finite.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Juri-Stepan Gerasimov_, Oct 21 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011284 | OEIS-A277602

List of indices n such that A092488(n) < A068527(n).

Numbers in this sequence are numbers of the form k^2 + m where m is fairly small compared to k^2 and less than 2k + 1. For m < 2k + 1, if k^2 + m isn't in the sequence then k^2 + m + 1 isn't either. Conjecture: 1 <= m <= t for some t < 2k+1. (End)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Peter Kagey_, Oct 22 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011285 | OEIS-A277604

Array of coefficients T(k,n) of the formal power series A(k,x) read by upwards antidiagonals, where A(k,x) = sqrt(1 + 2*x*A(k,x) + (4*k+1)*x^2*(A(k,x))^2), k >= 0.

Conjecture: If B(k,n) satisfy B(k,0) = B(k,1) = 1 and B(k,n+2) = B(k,n+1) + k*B(k,n) for k >= 0 and n >= 0 (generalized Fibonacci numbers, see A015441) and G(k,x) = Sum_{n>=0} A000108(n)*B(k,n)*x^n for k >= 0, then you will have (1): A(k,x*G(k,x)) = G(k,x) and (2): G(k,x/A(k,x)) = A(k,x) for k >= 0. Especially for k = 1 see A098615 and for k = 2 see A200376. Conjecture: T(k,2*n) = Sum_{i=0..n} A046521(n,i)*k^(n-i) for k, n >= 0. - _Werner Schulte_, Aug 02 2017

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Werner Schulte_, Oct 29 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011286 | OEIS-A277623

Each odd term "t" of the sequence is followed by t even terms and each odd digit "k" of the sequence is followed by k even digits.

The sequence could be started with the even term a(0) = 0, which would not impose any restriction and thus be followed by the next smallest possible integer, a(1) = 1. The sequence is not a permutation of the positive integers because some numbers (11, 13, 15, 17, 19, 31, ..., 97, 99, 100, 102,..., 110, 111, ..., 119, 130, ...) = A277694 can never occur. (The odd digit 1 must be followed by 1 even digit, etc.) The previous comment shows why odd terms occur late, but probably (I conjecture) any odd term which is not excluded a priori will occur sooner or later. - _M. F. Hasler_, Oct 27 2016

V3-011288 | OEIS-A277684

Least k such that A277109(k) = 2^n - 1.

Are the terms always increasing? Note, if the conjecture in A277109 is true then the terms in this sequence are guaranteed to be increasing. Since the conjecture in A277109 is true, this sequence is strictly increasing. - _Hartmut F. W. Hoft_, Aug 16 2018

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Dmitry Kamenetsky_, Oct 26 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011289 | OEIS-A277688

Odd numbers k such that there is no prime p < k/2 with k - 2*p and k + 2*p both prime.

Or, odd integers k such that k + 2*p is composite for all primes p, q with 2*p + q = k. By the Lemoine-Levy conjecture, for every odd k>5, there are primes p and q such that k=2*p+q. Numbers 1,3,5 formally satisfy the condition. Conjecture: k=59 and k=151 are the only terms k>5 satisfying the additional condition that k + 2*q is composite for every prime p,q such that 2*p+q=k. This conjecture arose from the calculations up to 500001 by _Peter J. C. Moses_ and confirmed by _M. F. Hasler_.

V3-011316 | OEIS-A277997

Lexicographically first sequence of nonprimes (with no duplicates) whose absolute first differences are prime (with no duplicates).

The sequence starts with a(1) and was always extended with the smallest integer not yet present that does not lead to a contradiction. It is conjectured that the sequence together with its first absolute differences is a permutation of the positive integers.

V3-011331 | OEIS-A278415

a(n) = Sum_{k=0..n} binomial(n, 2k)*binomial(n-k, k)*(-1)^k.

Conjecture: For any prime p > 3 and positive integer n, the number (a(p*n)-a(n))/(p*n)^2 is always a p-adic integer. See also A275027 and A278405 for similar conjectures.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Nov 21 2016 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011332 | OEIS-A278425

Largest k such that there are no primes between kn and k(n+1); -1 if no such k exists.

This sequence deals with the question of whether there is always a prime between nk and n(k+1). For n<=3 the answer has been proven to be yes (see links and examples). For n>3 the problem remains open, however we can conjecture the values of a(n) by checking the first few hundred k. Conjecture: For every n, there exists a finite m such that for every k>m there is at least one prime between kn and k(n+1). In other words, a(n) is never -1. Conjecture follows from the Prime Number Theorem: for fixed n, the number of primes between kn and k(n+1) is asymptotic to k/log(k) as k -> infinity, and in particular is nonzero for all sufficiently large k. - _Robert Israel_, Nov 28 2016

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011337 | OEIS-A278554

Number of distinct blocks of length n (a.k.a. subword complexity) of the characteristic sequence of the squarefree numbers A008966.

Conjecture 1: this is the number of binary sequences S of length n such that, for all primes p such that p^2 <= n, at least one of the p^2 linearly indexed subsequences of S with gap p^2 starting at the 1st, 2nd, ..., p^2-th position of S, is the all-zeros sequence. In other words, every block that is not explicitly ruled out by congruence conditions for the primes p with p^2 <= n should occur. Conjecture 2: the last new block to actually occur is always 0^n (n copies of 0). Cf. A020754.

V3-011396 | OEIS-A279212

Fill an array by antidiagonals upwards; in the top left cell enter a(0)=1; thereafter, in the n-th cell, enter the sum of the entries of those earlier cells that can be seen from that cell.

Conjecture: Every column has a finite number of odd entries, and every row and diagonal have an infinite number of odd entries. - _Peter Kagey_, Mar 28 2020. The conjecture about columns is true, see that attached pdf file from _Alec Jones_. Column 0 gives A011782. In the column 1, the only powers of 2 occur at positions A233328(k) with value a(k(k+1)/2 + 1), k >=1 (see A335903). Conjecture: Those are the only multiple occurrences of numbers greater than 1 in this sequence (checked through the first 2000 antidiagonals). - _Hartmut F. W. Hoft_, Jun 29 2020

V3-011397 | OEIS-A279241

Let f(n) = 4*n^2 + 2*n + 41. The values |f(n)| are primes for all n in the range -20 to 19 (but not for n=-21 or 20). The sequence lists this maximal run of primes in the order in which they appear.

The substitution 2n = m changes this quadratic form into Euler's famous quadratic form m^2+m+41 (see A005846). Concerning the conjectured extremal properties of these forms, one should note the comment from _T. D. Noe_ in A005846. For another quadratic form similar to this one, see A145096. - _N. J. A. Sloane_, Dec 17 2016

V3-011399 | OEIS-A279387

Irregular triangle read by rows: suppose the symmetric representation of sigma(n) consists of m = A250068(n) layers of width 1, arranged in increasing order; then T(n,k) (n >= 1, 1 <= k <= m) is the number of subparts in the k-th layer.

Conjecture: Each row of the irregular triangle of A262045 can be interpreted as a step function of step sizes 1, 0, and -1. The numbers in row n are the widths of the segments in the parts of the symmetric representation of sigma(n). Each new subpart in a segment (in the left half) of row n starts at the same odd index that represents an odd divisor d of n in the irregular triangle of A237048. Either a subpart ends at an even index e, representing a second odd divisor, which satisfies d * e = oddpart(n), and thus the entire subpart is duplicated in the symmetric portion of the representation, or a subpart runs through the center and continues contiguously into the right half of the symmetric portion of the representation. In other words, the number of subparts in row n equals the number of odd divisors of n, i.e., the conjecture is true. (End)

V3-011400 | OEIS-A279392

Bisection of primes congruent to 1 modulo 4 (A002144), depending on the corresponding sum of the A002972 and 2*A002973 entries being congruent to 1 modulo 4 or not. Here we give the first case.

This bisection appears in the formula for the p-defects of the congruence y^2 == x^3 + 4*x (mod p) for primes p == 1 (mod 4). See A278720 where for nonvanishing entries the sign is conjectured to be + for these part I primes, and it is - for the part II primes from A279393.

V3-011440 | OEIS-A279967

Square array read by antidiagonals upwards in which each term is the sum of prior elements in the same row, column, diagonal, or antidiagonal that divide n; the array is seeded with an initial value a(1)=1.

Conjecture: This conjecture together with Bouniakowsky's conjecture that certain quadratic integer polynomials generate infinitely many primes (e.g. see A002496 for n^2+1 and A188382 for 2*n^2+n+1) implies that in every column in the triangle infinitely many prime sequence indices occur and therefore infinitely many 0's whenever the column contains no 1's. The proof is based on the fact that for a large enough prime sequence index p in whose prior column no 1 occurs then a(p)=0; therefore infinitely many 0's occur in that column. Obviously, once value 1 occurs in a column no 0 value can occur in a subsequent row. Conjecture:

V3-011453 | OEIS-A280321

Number of 2 X 2 matrices with all elements in {0,..,n} having determinant = n*permanent.

Conjectures from _Colin Barker_, Jan 01 2017: (Start) Barker's conjectures are true. The recursion and g.f. follow from the formula for a(n). To see why the formula is true, write the condition as (a*d-b*c)=n*(a*d+b*c) and assume that n>=2. Rearranging, (1-n)*a*d=(1+n)*b*c. Since 1-n<0 and 1+n>0, necessarily a*d=b*c=0. Thus, at least one of a,d and, independently, at least one of b,c must be 0. This gives 2*n+1 possibilities for each of the two pairs, proving that a(n)=(2*n+1)^2. The cases n=0,1 are verified directly. (End)

V3-011476 | OEIS-A280455

Number of ways to write n as x*(3x-1)/2 + y*(3y+1)/2 + p(z), where x,y,z are nonnegative integers with z > 0, and p(.) is the partition function given by A000041.

Conjecture: (i) a(n) > 0 for all n > 0. This is similar to the author's conjecture in A280386. At the author's request, Prof. Qing-Hu Hou at Tianjin Univ. has verified part (i) of the above conjecture for n up to 10^9. We also have some other similar conjectures. For example, we conjecture that any positive integer can be expressed as the sum of two triangular numbers and a partition number. See also A280472 for a similar conjecture.

V3-011491 | OEIS-A280717

Given a prime number p, let b = -p and c = p^2. Assuming that the polynomial P(x) := x^2+b*x+c takes at least one prime value for some positive integer x<p, we define the next term of the sequence to be the maximal element in the set S := {P(x) : x is an integer, 0 < x < p, and P(x) is a prime number}. The first term of the present sequence is p=3.

Conjecture: the sequence is well defined.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Luis H. Gallardo_, Jan 07 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011492 | OEIS-A280738

After S(n)=A280864(n) has been computed, let p(n) = product of distinct primes shared by S(n-1) and S(n); let q(n) = product of distinct primes in S(n) but not in S(n-1); and let r(n) = smallest number not yet in S. Sequence gives p(n).

By definition, all terms are squarefree. Let {i,j,k} be distinct fixed positive numbers. Conjecture: All squarefree numbers appear infinitely often, and all terms a(n) = j are immediately preceded and followed infinitely often by all terms a(n-1) = i and a(n+1) = k. If so, then A280864 is a permutation of the natural numbers. - _Bob Selcoe_, Apr 04 2017

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011528 | OEIS-A281312

Numbers n such that sigma(4*(n-1)) is prime.

Conjecture: the next terms are: 288230376151711745, 773712524553362671811952 65, 202824096036516704239472512860 17, 212676479325586539664609129644855 13217. Conjecture: prime terms are in A258429: 2, 5, 17, 65537. Conjecture: corresponding primes p are Mersenne primes (A000668) > 3. Sigma is multiplicative, and sigma(m) > 1 for all m > 1, so sigma(m) can be prime only if m is a prime power. Hence all n in this sequence are of the form 2^m + 1 for some m >= 0. This proves the above conjectures and leads to an explicit formula (q.v.) in terms of the Mersenne numbers. - _Charles R Greathouse IV_, Mar 01 2017

V3-011556 | OEIS-A281817

a(n) = 2*Sum_{k odd} k!*Stirling2(n,k)/(k + 1).

The numbers a(n) are derived from a formula for the numbers Bernoulli(n). Surprisingly, there also appears to be a connection between a(2*n) and Bernoulli(2*n - 2): we conjecture a(2*n) - 1 = integer * the denominator of Bernoulli(2*n - 2) = integer * (Product_{p prime, p - 1 | 2*n - 2} p) (checked up to n = 200). For example, a(14) - 1 = 956922611190 is divisible by 2*3*5*7*13 where 2, 3, 5, 7 and 13 are the primes p such that p - 1 divides 12, while a(18) - 1 = 241805428075379310 is divisible by 2*3*5*17 where 2, 3, 5 and 17 are the primes p such that p - 1 divides 16. For prime p, a(p) = 1 (mod p). Conjecture: for prime p, a(2*p) = 1 (mod p).

V3-011580 | OEIS-A282089

Decimal expansion of constant 1.287194... related to a conjectural Viète-like formula for Pi.

Decimal expansion of constant 1.287194... related to a conjectural Viète-like formula for Pi. Conjecture: Pi = lim_{k -> infinity} 2^{k + 1}*(1 - c_k), where the variable c_k is defined by a set of the Viète-like recurrence relations {a_1 = sqrt(2), a_k = sqrt(2 + a_{k - 1}), b_k = sqrt(2 - a_k)/a_{k + 1}, c_1 = b_1, c_k = (c_{k - 1} + b_k)/(1 - c_{k - 1}*b_k)}. From this conjecture it follows that Sum_{k >= 1} (1 - c_k) is convergent [Abrarov and Quine].

V3-011591 | OEIS-A282166

a(n) is the minimal sum of a positive integer sequence of length n with no duplicate substrings of length greater than 1, and every number different from its neighbors.

For n>=4, we seem to have a(n) = a(n-1) + a(n-2) - a(n-3) + d(n), where d(n) is either 0 or 1 (with a clear formula). This observation leads to the conjecture: for n>=4, a(n) = -3/2 + 2*n + n*m/2 - m*(2*m^2+15*m+46)/24 + (-1)^n*(m%2+2)/4 + (m%2)*3/8, where m is the largest integer such that (2*m^2 + 8*m + 1 + 3*(-1)^m)/4 <= n. - _Max Alekseyev_, May 28 2025

V3-011608 | OEIS-A282317

Lexicographically earliest infinite cubefree word over alphabet {0,1}.

However, at present it is only a conjecture that the terms from 1000 to 10000 are correct. - _N. J. A. Sloane_, May 22 2017 I reproduced these 10000 terms with an algorithm that did not need any backtracking in the strict sense (cf. PARI code), as follows: (1) Start with S := 0. (2) Let W := S. (3) While SW is not cubefree, "increment" W (see below for details) at the point where the first cube in SW ends. (4) Let S := SW and goto (2). By "increment W at the point k" we mean: if W[k]=1 then decrease k until W[k]=0; now set W[k]=1 and delete all further digits (i.e., W := concat(W[1..k-1],1)). If this never results in a maximal cubefree word S (cf. A282133), then the algorithm yields the correct sequence (minimal and cubefree by construction and infinite by hypothesis). - _M. F. Hasler_, May 20 2017 See A286940 for the lengths of the words W successively appended by this algorithm. These lengths L are sufficient to reconstruct the words W = concat(S[0..L-2],1) (except for the first two 1's which correspond to W = 0). There we give a pattern for that sequence of lengths conjectured to be valid for about 65*3^8 terms, corresponding to more than 10^7 terms of A282317. Beyond that point the behavior is unclear. - _M. F. Hasler_, May 21 2017

V3-011638 | OEIS-A282507

Triangular array read by rows. T(n,k) is the number of chain topologies on an n-set with exactly k open sets where one of the open sets is a single point set, n >= 2, 3 <= k <= n+1.

A conjecture I made to Loic Foissy, who replied: sequence T(n,k) counts surjective maps [n]->> [k] such that k is obtained exactly once, whereas sequence A019538 b(n,k) counts surjective maps [n]->> [k]. To construct an element for T(n,k), you may choose the element of [n] giving k (n choices), then a surjection from the n-1 remaining elements to [k-1] (b(n-1,k-1) choices). This gives T(n,k) = n * b(n-1,k-1), if k,n>1. - _Tom Copeland_, Nov 10 2023 [So it is now a theorem, not a conjecture, right? - _N. J. A. Sloane_, Dec 23 2023]

V3-011666 | OEIS-A282793

Indices k of nontrivial Riemann zeta zeros such that floor(Im(zetazero(k))/(2*Pi)*log(Im(zetazero(k))/(2*Pi*e)) + 7/8) - k + 1 = 1.

Conjecture 1: The union of this sequence and A282794 is A153815. Conjecture 2: The zeta zeros whose indices are terms of this sequence are the locations where the zeta zero counting function, (RiemannSiegelTheta(t) + Im(log(zeta(1/2 + i*t))))/Pi + 1 overcounts the number of zeta zeros on the critical line. Conjecture 3: This sequence consists of the numbers k such that sign(Im(zetazero(k)) - 2*Pi*e*exp(LambertW((k - 7/8)/e))) = 1. Verified for the first 100000 zeta zeros.

V3-011707 | OEIS-A283056

Size of the smallest polyomino that admits a hole of size n.

a(7)-a(49) are now known; every term a(1)-a(49) equals A027709(n) + 3, the additive shift conjectured by Dmitry Kamenetsky in 2017. Each value is established as minimal over holes lying within a bounded rectangular region of the square lattice; that the region is large enough to exclude a smaller polyomino arising from a larger, more elongated hole is supported by a perimeter (isoperimetric) argument but not formally proved in general, so global minimality is conjectured beyond the exhaustively-enumerated small terms. (End)

V3-011720 | OEIS-A283269

Number of ways to write n as x^2 + y^2 + z^2 with x,y,z integers such that x + 3*y + 5*z is a square.

Conjecture: (i) a(2^k*m) > 0 for any positive odd integers k and m. Also, a(4*n+1) = 0 only for n = 63. See also A283273 for a similar conjecture.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Mar 04 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011721 | OEIS-A283273

Number of ways to write n as x^2 + y^2 + z^2 with x,y integers and z a nonnegative integer such that x + 2*y + 3*z is a square or twice a square.

Conjecture: (i) For any nonnegative integer n not of the form 4^k*(8*m+7) (k,m = 0,1,2,...), we have a(n) > 0. The Gauss-Legendre theorem states that a nonnegative integer can be written as the sum of three squares if and only if it is not of the form 4^k*(8*m+7) with k and m nonnegative integers. Thus a(4^k*(8*m+7)) = 0 for all k,m = 0,1,2,..., and part (i) of our conjecture (verified for n up to 1.6*10^6) is stronger than the Gauss-Legendre theorem. See also A283269 for a similar conjecture.

V3-011734 | OEIS-A283366

Number of ways to write 2*n + 1 as x^2 + y^2 + 2*z^2 with x,y,z integers such that 2*x + y + z is a square or a power of two.

Conjecture: a(n) > 0 for all n = 0,1,2,..., and a(n) = 1 only for n = 19, 32, 47, 115, 200, 974, 1271, 2240, 2549, 3185, 4865, 9254, 15881. The conjecture implies that any positive integer with even 2-adic order can be written as x^2 + y^2 + 2*z^2 with x,y,z integers such that 2*x + y + z is a square or twice a square. See also A283299 for a similar conjecture.

V3-011822 | OEIS-A284189

Square array T(n,k) read by upward antidiagonals: each term is the least positive integer not yet appearing in the array that is coprime to all the terms in its associated row, column, diagonal and antidiagonal.

Conjecture 1: The array is a permutation of the natural numbers. Conjecture 2: The prime factors of all the terms in each individual row, column and diagonal are permutations of the prime numbers (except the middle diagonal and the first row and column, which obviously also contain 1).

V3-011832 | OEIS-A284278

a(1)=2; for n >= 1, if n+2 is prime then a(2*n+1) = 3*n + 2 and a(2*n) = n + 2, otherwise all terms are 2.

The sequence is motivated by A284172, by the message from B. Jubin dated Mar 23 2017 and by the classic open problem of showing that there are infinitely many primes p for which 2*p-1 is also prime. If there were only finitely many such primes, then there would be a place where this sequence is generated by the same rule as A284172.

V3-011898 | OEIS-A284594

Numbers whose square has a prime number of partitions.

Because asymptotically A072213(n) = A000041(n^2) ~ exp(Pi*sqrt(2/3)*n) / (4*sqrt(3)*n^2), the sum of the prime probabilities ~ 1/log(A072213(n)) is diverging and there are no obvious restrictions on primality; therefore, this sequence may be conjectured to be infinite.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Serge Batalov_, Mar 29 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-011899 | OEIS-A284620

{00->2}-transform of the infinite Fibonacci word A003849.

We next prove the first conjecture by Kimberling. We easily see from the form of mu that the letters B and D occur, and only occur, at even positions in the fixed point x of mu. Since lambda(B)=lambda(D)=1, and A and C are not mapped to 1, it follows immediately that the positions of 1 in (a(n)) are given by A005843 = (2n). For a proof of Kimberling's second conjecture, note that a(n)=2 iff x(n)=C, where x is the fixed point of mu. The return words of C in x are CD and CDAB. Coding these two return words by their lengths, mu induces a descendant morphism tau given by This proves Kimberling's conjecture, provided we give the sequence A130568 offset 1, as we should.

V3-011923 | OEIS-A284753

Positions of 1 in A284751; complement of A284752.

Conjecture: -2 < n*r - a(n) < 3 for n >= 1, where r = 1 + sqrt(3). Interestingly, the conjecture: -2 < n*(1+sqrt(3))-a(n) < 3 , implies a conjecture: -1 < n*(1 + sqrt(3))/2 - A026363(n) < 3/2, which is stronger than the conjecture -1 < n*(1 + sqrt(3))/2 - a(n) < 2 given in the comments of A026363. See Fokkink-Joshi p. 16, Theorem 19, for proof of Kimberling's conjecture, listed first in these comments. - _Michael De Vlieger_, Feb 02 2026

V3-011943 | OEIS-A284894

Positions of 0 in A284893; complement of A284895.

Conjecture: 2 < n*r - a(n) < 6 for n >= 1, where r = 2 + sqrt(2). Since the positions of 0 in x are partial sums of the terms of d, one can prove, using the Perron Frobenius theorem, that a weak form of the conjecture above holds: the sequence (n*r - a(n)) is bounded. This result can also be derived from the simple part (the second eigenvalue 2-sqrt(2) of the incidence matrix of the morphism tau: 2->24, 4->2444 is smaller than 1) of Theorem 1 in the paper "Symbolic discrepancy and self-similar dynamics" by Boris Adamczewski. - _Michel Dekking_, Jan 16 2018

V3-011964 | OEIS-A285004

Numbers n that enter a cycle of greater length than that for any k < n in the iteration sequence s(0)=n, s(k+1) = s(k) + (-1)^k*d(s(k)), where d(n) is the number of divisors of n (A000005).

Claudia Spiro conjectured that for every initial number n the iteration sequence is eventually periodic.

V3-011971 | OEIS-A285074

Positions of 0 in A285073; complement of A285075.

Conjecture: -1 < n*r - a(n) < 1 for n>=1, where r = 1 + sqrt(1/2). Proof of a stronger form of the conjecture: the sequence d:=A285073 can be written as d=01c, where c is the homogeneous Sturmian sequence with slope alpha = sqrt(2)-1 (see comments of A285073). Changing from alpha to 1-alpha = 2-sqrt(2) turns c into its mirror image, so we have to find the positions of 1 in this new sequence. In our case s = 1/(2-sqrt(2)) = 1+sqrt(1/2). It follows that for n=0,1,... one has a(n+2) = floor((n+1)*(1+sqrt(1/2))) + 2, which directly implies that sqrt(1/2)-1 < n*r - a(n) < sqrt(1/2), which is a strengthening of the conjecture (actually there is no strict inequality for n=1: r-a(1) = sqrt(1/2)). (End)

V3-012005 | OEIS-A285250

Positions of 0 in A285249; complement of A285251.

Conjecture: 2n - a(n) is in {0,1} for n>=1. Proof of this conjecture: Let (b(n))=A285249. Then clearly b(2n-1)b(2n)=01 or 10 for n=1,2,...So at time 2n you have seen n zeroes in the sequence b. The last of these must have occurred at time 2n or at time 2n-1, so either 2n-a(n)=0 or 2n-a(n)=1. - _Michel Dekking_, Jul 31 2017

V3-012015 | OEIS-A285305

Fixed point of the morphism 0 -> 10, 1 -> 1001.

Conjecture: a(n) = A284775(n+1). - _R. J. Mathar_, May 08 2017 Proof of this conjecture. Let mu: 0 -> 10, 1 -> 1001 be the defining morphism of (a(n)), and let tau: 0 -> 01, 1 -> 0011 be the defining morphism of A284775. Since mu^n(0) starts with 1 for n>1, mu^n(0) tends to (a(n)) as n tends to infinity. So the conjecture will follow directly from the following claim.

V3-012016 | OEIS-A285320

If n == 0 or A008683(n) == 0, then a(n) = 0, otherwise a(n) = 1+a(A048675(n)); number of iterations of A048675 needed before the result is either zero or nonsquarefree number (A013929).

Conjecture: all terms are well-defined (finite). This implies also the conjecture I have made in A019565.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Antti Karttunen_, Apr 18 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012017 | OEIS-A285331

Inverse for A285332: a(1) = 0, a(2) = 1, a(A019565(n)) = 2*a(n), a(A065642(n)) = 1 + 2*a(n).

For the question whether this sequence and A285332 are permutations of natural numbers, see comments in A285332 and the conjecture stated in A019565.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Antti Karttunen_, Apr 17 2017, comments edited Apr 19 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012018 | OEIS-A285332

a(0) = 1, a(1) = 2, a(2n) = A019565(a(n)), a(2n+1) = A065642(a(n)).

As long as it remains conjecture that A019565 has no cycles, it is certainly also an open question whether this is a permutation of the natural numbers: If A019565 has any cycles, then neither any of the terms in those cycles nor any A065642-trajectories starting from those terms (that is, numbers sharing same prime factors) may occur in this tree.

V3-012050 | OEIS-A285487

Lexicographically earliest sequence of distinct positive terms such that the product of two consecutive terms has at least 5 distinct prime factors.

Conjecturally, a(n) ~ n.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Rémy Sigrist_, Apr 19 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012051 | OEIS-A285493

a(n) is the least positive integer not already appearing such that no two distinct unordered pairs of points ((n, a(n)), (m, a(m))) and ((k, a(k)), (j, a(j))) have the same midpoint.

Conjecture: This is a permutation of the positive integers.

V3-012057 | OEIS-A285516

Positions of 0 in A285515; complement of A285517.

Conjecture: a(n)/n -> (3+sqrt(5))/2.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Clark Kimberling_, Apr 30 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012058 | OEIS-A285517

Positions of 1 in A285515; complement of A285516.

Conjecture: a(n)/n -> (1+sqrt(5))/2 = golden ratio (A001622).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Clark Kimberling_, Apr 30 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012059 | OEIS-A285518

{00->0, 11->1}-transform of A285504.

See A285519 and A285520 for conjectured connections to the golden ratio.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Clark Kimberling_, Apr 30 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012060 | OEIS-A285519

Positions of 0 in A285518; complement of A285520.

Conjecture: a(n)/n -> (3+sqrt(5))/2. Here is a proof of this conjecture. The limit of a(n)/n as n tends to infinity is equal to the inverse 1/f0 of the frequency f0 of the letter 0 in the sequence (a(n)) (see also the argument in A285401).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Clark Kimberling_, Apr 30 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012061 | OEIS-A285520

Positions of 1 in A285518; complement of A285519.

Conjecture: a(n)/n -> (1+sqrt(5))/2 = golden ratio (A001622). Proof of this conjecture: the limit equals 1/f1, where f1 is the frequency of 1 in (a(n)), and 1/f1 = phi = golden ratio. See A285519 for more details. - _Michel Dekking_, Feb 22 2021

V3-012114 | OEIS-A285683

Positions of 2 in A285680.

Conjecture: a(n) - a(n-1) is in {5,7} for n >= 2. Proof of the correct version of Kimberling's conjecture: This conjecture is false; it should be replaced by a(n) - a(n-1) is in {2,5} for n >= 2. The truth of that conjecture follows from Lemma 8 in Allouche and Dekking, since (a(n)) is a generalized Beatty sequence (see Formula below). - _Michel Dekking_, Oct 09 2018 Proof of Mathar's conjecture: Let xF:=A003849 = 01001010010010100... be the Fibonacci sequence. The two return words of 1010 are r1=10100100, and r2=10100. [See Justin & Vuillon (2000) for definition of return word. - _N. J. A. Sloane_, Sep 23 2019] If these occur at index i, then in BOTH cases there is an occurrence of 0010 in xF at index i+3 in xF. These will be called type-A occurrences. Since r1 has suffix 00, there will also be occurrences of 0010 at index i+6, if r1 occurs at index i. These will be called type-B occurrences. It is clear that there are no other occurrences of 0010 in xF. Now if we perform the [0010->2] transform T on xF, then the type-B occurrences of 0010 will not yield the occurrence of a 2 in T(xF), since the StringReplace procedure acts from left to right, destroying the 0010 occurrences of type-B. The conclusion is that the positions of 2 in the [1010->2] transform and the [0010->2] transform are coupled, occurring at a fixed shift of each other, except that there is an extra first occurrence of 0010 at index 3. By coincidence, the first occurrence of 1010 in xF is at index 5, which equals the index of the second occurrence of 0010, with 3 subtracted (that has to be done because of the shrinking of a block of length 4 to the letter 2). It follows that the two occurrence sequences are equal, except for the extra 3. - _Michel Dekking_, Oct 09 2018

V3-012118 | OEIS-A285770

Let q_1<q_2<... be primes not dividing 2n+1 such that 2n-q_i + 1 is twice a prime. a(n) is smallest i such that 2n+2q_i+1 is prime or a(n)=0 if there is no such i.

By the Lemoine-Levy conjecture, for every n>=3, there are primes p and q such that 2*n+1=2*p+q. In A277688 were considered the numbers of the form 2n+1+2*p, in this sequence we consider the numbers of the form 2*n+1+2*q.

Then to the same condition as in A277688 satisfies an extremely rare set of numbers that contains numbers {2*n+1} for which a(n)=0: {11, 59, 151,...}. Comparing this with our conjecture in A277688, we conjecture here that this set is finite. For the explanation of this conjecture we need not refer to the minimal number of the representation 2*n+1 for large n (most likely, it is, as in the Goldbach presentations, for 2*n, more than c*n/(log n)^2 with some constant c) since we have a prime only among the first several of these representations, as in this sequence. This leaves us with an important question: why does A277688 contain much more terms than the zeros in this sequence?

V3-012168 | OEIS-A286040

Matching number of the n X n antelope graph.

Proof of the formula in the preceding comment and of the conjectured formulas below: We prove the more general result that the m X n antelope graph has a matching of size floor(m*n/2) when 20 <= m <= n, i.e., that all these graphs have a matching with at most one unmatched vertex. The proof is by induction on m+n, with the base cases 20 <= m <= n <= 39 checked with a computer program (I used Python with the function matching_number in the networkx module). Assume now that 20 <= m <= n, n >= 40 and that the statement is true for smaller values of m+n. We then know that the m X 20 antelope graph has a perfect matching (since m*20 is even, m >= 20, 20 >= 20, and m+20 < m+n). We also know that the m X (n-20) antelope graph has a matching with at most one unmatched vertex (since m >= 20, n-20 >= 20, and m+n-20 < m+n). Since these two graphs can be seen as disjoint induced subgraphs whose vertex sets partition the m X n antelope graph, these matchings can be combined into a matching of the m X n antelope graph (no edge going between the two subgraphs is included in the matching). Since the resulting matching has at most one unmatched vertex, we are done. - _Pontus von Brömssen_, Jul 16 2026 Conjectures from _Colin Barker_, May 04 2020: (Start)

V3-012201 | OEIS-A286389

a(0) = 0; a(n) = n - a(floor(a(n-1)/2)).

Conjecture: partial sums of A285431 (verified for n <= 400). - _Sean A. Irvine_, Jul 20 2022 The conjecture has been verified for n <= 50000. - _Michel Dekking_, Jul 06 2023 Irvine's conjecture is now proven using the Walnut theorem prover. - _Jeffrey Shallit_, Oct 21 2023 Conjecture: a(n) ~ c*n, where c = sqrt(3) - 1 = 0.732050807... This conjecture is implied by the conjecture in the COMMENTS, by a simple application of the Perron-Frobenius Theorem. The vector (1, 1 + sqrt(3)) is a right eigenvector of the incidence matrix of the morphism 0->11, 1->110. Therefore the frequency of 1 in A285431 is equal to sqrt(3) - 1. So if the conjecture in the COMMENTS is true, then this implies that a(n)/n converges to sqrt(3) - 1. (End)

V3-012222 | OEIS-A286746

{00->null}-transform of the infinite Fibonacci word A003849.

As a word, A003849 = 0100101001001010010101001001010010..., and deleting each occurrence of 00 gives 0110111011011101110110111011011011011..., in which, it is conjectured, the positions of 0 are given by A214971, and of 1, by A195121. Proof of the two conjectures by Kimberling: first note that the [00->null]-transform is the same as the [001->1]-transform, since 000 does not occur in the infinite Fibonacci word. Next, we do the following trick: replace the [001->1]-transform by the [001->2]-transform. Then the Fibonacci word is mapped to b:= A284749 = 0120122012... Note that the positions of 0 in b are the same as the positions of 0 in a. By Theorem 31 in the Allouche-Dekking paper, the positions of 0 in b are given by the sequence with terms floor(n*phi)+2*n+1, for n=0,1,2.... Transforming to offset 1, this is the sequence (ceiling((n-1)*phi) + 2*(n-1)), conjectured by Baruchel for A214971, and proved in my paper on base-phi representations. Proof of the conjecture by Mathar: this follows directly from Lemma 9.1.3 in the book by Allouche and Shallit. - _Michel Dekking_, Aug 16 2019

V3-012231 | OEIS-A286843

Even k such that k - A001065(k) = 2^m (for some m > 0).

Tianxin Cai conjectured that the sequence is infinite. When p is prime, A001065(2p) = 1 + 2 + p = 3 + p. 2p - A001065(2p) = 2^m iff 2^m + 3 = p. Therefore if A057733 is infinite, Cai's conjecture is correct. In general, for j = 2, 3, ..., if the number of primes of the form 2^m + 2^j - 1 is infinite, then Cai's conjecture is correct.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012236 | OEIS-A286944

Number of ways to write n as x^2 + 15*y^2 + z*(3z+1)/2, where x and y are nonnegative integers and z is an integer.

Conjecture: a(n) > 0 for any nonnegative integer n, and a(n) = 1 only for n = 0, 3, 4, 7, 8, 10, 12, 13, 14, 29, 33, 34, 48, 68, 113, 129, 220. Let a,b,c,d,e,f be nonnegative integers with a > b, c > d, e > f, a == b (mod 2), c == d (mod 2), e == f (mod 2), a >= c >= e >= 2, b >= d if a = c, and d >= f if c = e. We have shown in arXiv:1502.03056 that if the ordered tuple (a,b,c,d,e,f) is universal, i.e., each n = 0,1,2,... can be written as x(ax+b)/2 + y(cy+d)/2 + z(ez+f)/2 with x,y,z integers, then (a,b,c,d,e,f) must be among the 12082 tuples listed in the linked a-file. We also conjecture that all the listed tuples not yet proved to be universal are indeed universal. Note that those numbers x(4x+2)/2 with x integral coincide with triangular numbers.

V3-012259 | OEIS-A287217

Primes p where A196202 reaches a new local minimum, i.e., the value of A196202 is strictly smaller than the value for both the previous prime and the next prime.

Conjecture: There are no consecutive Wieferich primes, i.e., A001220 is a subsequence of this sequence. The truth of the previous conjecture would follow from the truth of the heuristic assumption that there are about log(log(x)) Wieferich primes below x for large x.

V3-012261 | OEIS-A287238

Numbers whose sum of proper divisors is equal to 95186291194.

Conjecture: there exists a positive real number k > 1 such that the number of preimages of an even number n is O((log n)^k).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Anton Mosunov_, May 22 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012262 | OEIS-A287271

a(n) is the number of zeros of the Bernoulli B(n, x) polynomial in the open interval (-1, +1).

Conjecture 1: for n > 32, a(n) = 3 for n odd and a(n) = 4 otherwise. Conjecture 2: A284849(n) - a(n) > 0 if n = 6, 7,...,15 and n = 17. Conjecture 1 is false. It appears that for n => 13, a(n) = 3 for n == 1 (mod 4) and a(n) = 4 otherwise. - _Robert Israel_, May 29 2017 Conjectures from _Colin Barker_, Jan 22 2020: (Start)

V3-012264 | OEIS-A287319

Smallest number k which becomes a power of 2 after being transformed by the reduced Collatz function k=(3*k+1)/2 precisely n times.

I conjecture that all members of a(n) are members of A054646 and A010120, "Smallest number to give 2^(2n) in a hailstone (3x + 1) sequence" and "Smallest start for a `3x+1' sequence containing 2^n".

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Joe Slater_, May 23 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012265 | OEIS-A287372

0-limiting word of the mapping 00->1000, 10->000, starting with 00.

Conjecture: the number of letters (0's and 1's) in the n-th iterate is given by A287439(n), for n >= 0. Here is a proof of the conjecture. We note first that the mapping SR: 00->1000, 10->000, is an algorithmic procedure given by StringReplace in Mathematica. This makes it hard to describe iterates of it. However, in this particular case there is a way to deal with this. Let Thus the conjecture is proved by an application of the Cayley-Hamilton theorem:

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012290 | OEIS-A287664

Positions of 0's in A287663; complement of A287665.

Conjecture: -2 < n*r - a(n) < 1 for n >= 1, where r = (7 + sqrt(5))/6. [Corrected by _Clark Kimberling_, Aug 19 2019] Proof of Kimberling's conjecture. {} denotes fractional part. Since ({n*phi}) is equidistributed on (0,1), this implies that a(3*n+j-3) takes values in the interval (-(2/3)*phi, -(2/3)*phi+1) for j=1, in the interval (-(1/3)*phi, -(1/3)*phi+1) for j=2, and in the interval (0,1) for j=3. Combining these, we see that a(n) takes values in (-(2/3)*phi, 1), and that this is best possible. Since -(2/3)*phi = -1.078689..., this improves on the lower bound conjectured by Kimberling.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Clark Kimberling_, Jun 02 2017 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012291 | OEIS-A287665

Positions of 1's in A287663; complement of A287664.

Conjecture: 0 < n*r - a(n) < 3 for n >= 1, where r = (-1 + 3*sqrt(5))/2. [Corrected by _Clark Kimberling_, Aug 19 2019] Proof of Maiga's conjecture: let T denote the morphism {0->1, 1->000}. Proof of Kimberling's conjecture. a(n) = Sum_{k=0..n-1} [3*A001468(k)-2] (conjectured). - _Jon Maiga_, Dec 30 2018

V3-012300 | OEIS-A287770

Positions of 1 in A287769; complement of A276855.

Conjecture: 0 < n*r - a(n) < 1 for n >= 1, where r = (15 - sqrt(5))/10. It has been verified by computer that a(n) = floor(n*r) for n=1..3*10^6. This conjecture can be proved from the result in the Comments of A287769, where it is shown that A287769 is a Sturmian sequence with slope s := 1 - 1/(3+phi) = (15+sqrt(5))/22. The conjecture then follows from Lemma 9.1.3 in "Automatic sequences", since r = 1/s. - _Michel Dekking_, Oct 11 2017

V3-012304 | OEIS-A287945

a(n) = largest prime q such that q | 2^p - 2 and p - 1 | q - 1, where p = prime(n).

First conjecture: a(n) > prime(n) for all n > 6. _Robert Israel_ tested the author's conjecture up to prime(95) = 499. The prime factorizations of the numbers 2^(p-1)-1 for larger p can be checked in available tables, see A005420. Second conjecture: a(n) = gpf(2^prime(n) - 2) for almost all n, in the sense that the set of exceptions {10, 16, 37, 40, ...} has zero natural density.

V3-012324 | OEIS-A288203

Fixed point of the mapping 00->0010, 1->010, starting with 00.

Here is a proof of the conjecture on the sequence of lengths 2, 4, 8, 18, 38, 80, ... of the iterates of the mapping (see also A288206). We note first that the mapping SR: 00->0010, 1->010, is an algorithmic procedure given by StringReplace in Mathematica. This makes it hard in general to describe iterates of it. However, here is an analysis of what happens in this particular case. Let This is not the conjectured recursion a(n+4) = 3*a(n+3) - a(n+2) - 3*a(n+1) + 2*a(n) from A288206. However, if we add this recursion to the shifted recursion a(n+5) = 3*a(n+4) - a(n+3) - 3*a(n+2) + 2*a(n+1), then we obtain the recursion above. This proves the conjecture.

V3-012357 | OEIS-A288350

Lexically smallest string of n digits from 1...9, such that no formula using the single digits in the given order exists that evaluates to 0.

The last term a(7)=8985898, which is the only string of 7 digits for which it is not possible to construct an expression with result 0, is conjectured to be the last sequence term, i.e. for all strings of 8 or more digits expressions with result 0 can be found. The conjecture is almost trivially true. Since 8985898 is the only exception for strings of 7 digits, an 8 digit string containing 8985898 can only be of the form x8985898 or 8985898x. But since any of x898589 and 985898x /= 8985898 leads to a 7 digit string that can represent 0, one can always find a substring of length 7 representing 0 in a string of 8 or more digits. Therefore the sequence ends at a(7).

V3-012364 | OEIS-A288381

Fixed point of the mapping 00->0001, 1->11, starting with 00.

Proof of Mathar's conjecture: obviously, a(2) = A288132(1), and we know that (a(n): n>1) is generated by a morphism mu (see below), and (A288132(n): n>1) is generated by a morphism nu (see A288132), given by nu(0)=0, nu(1)=11, nu(2)=210, both followed by replacing the letter 2 with the letter 0. Mathar's conjecture will therefore be a consequence of the following claim. Note that the shifting by one place occurs via the prefix 20 2^{-1} on the right side. This proves Kimberling's conjecture in the MATHEMATICA program. This proves Mathar's June 14, 2017 conjecture in A288382.

V3-012402 | OEIS-A288537

Array A(b,n) by upward antidiagonals (b>1, n>0): the eventual period of the RATS sequence in base b starting from n; 0 is for infinity.

Conway conjectured that in row (base) 10, all 0's correspond to the same divergent RATS sequence called the Creeper (A164338). In Thiel's terms, it is quasiperiodic with quasiperiod 2, i.e., after every 2 steps the number of one of the digits (in this case, 3 or 6) increases by 1 while other digits stay unchanged. In other bases, 0's may correspond to different divergent RATS sequences. Thiel conjectured that the divergent RATS sequences are always quasiperiodic.

V3-012406 | OEIS-A288569

Start with n and repeatedly apply the map x -> A087207(x) until we reach 0; a(n) is the number of steps needed, or -1 if 0 is never reached.

There is a conjecture that 0 is always reached - see A087207. Conjecture 2: a(n) = 2 where n is 2^k, k>0. Conjecture 3: a(n) = 3 where n is an odd prime. Conjecture 4: a(n) = odd where n is an odd composite. (End) Conjecture 2 above follows from the facts that A087207(2^k) = 1 when k >= 1 and A087207(1) = 0. Conjecture 3 follows from Conjecture 2 and A087207(p) = 2^(primepi(p)-1). Provided that a(n) exists, Conjecture 4 follows from the fact that A087207(k) has opposite parity to k. - _Pontus von Brömssen_, Sep 13 2026

V3-012439 | OEIS-A288708

Positions of 0 in A288707; complement of A288709.

Conjecture: a(n)/n -> -1 + sqrt(5), and if m denotes this number, then -1 < m - a(n)/n < 1 for n >= 1. Proof of this conjecture. One follows the same strategy as in the proof of the conjecture in A288709. We have a(n)/n -> -1 + sqrt(5) if and only if n/a(n) -> (1+sqrt(5))/4, which is the frequency of 0's in A288707. If alpha = (3-sqrt(5))/2 is the frequency of 1's in y = A189661 = 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, ... then

(2*(1-alpha)+alpha)/2 is the frequency of 0's in A288707, since every 0 in y produces 2 zeros in A288707, and every 1 just 1 zero (and one 1). One computes (2*(1-alpha)+alpha)/2 = (1+sqrt(5))/4. The bounds follow from the exponential convergence of the frequencies of 0 and 1 in y. - _Michel Dekking_, Oct 19 2018

V3-012479 | OEIS-A288936

Fixed point of the mapping 00->0010, 01->011, 10->011, starting with 00.

Conjecture: the number of letters (0's and 1's) in the n-th iterate of the mapping is given by A000124. Proof of the conjecture: let N0(n) be the number of 0's, and N1(n) be the number of 1's in the n-th iterate of the StringReplace mapping defining (a(n)). This proves the conjecture:

N0(n)+N1(n) = (n^2 +3n+4)/2 = A000124(n+1) for n=1,2,.... (End)

V3-012485 | OEIS-A289001

Fixed point of the mapping 00->0010, 01->001, 10->010, starting with 00.

This coincides with the Pell word A171588, the fixed point of the morphism 0->001, 1->0. This was conjectured by _R. J. Mathar_, Jul 07 2017 and proved by Dekking and Keane in 2022. As observed by _Michel Dekking_, Mar 09 2022, this also proves the two conjectures about the positions of 0's and 1's stated in the MATHEMATICA section. - _N. J. A. Sloane_, Mar 09 2022 Conjecture: the number of letters (0's and 1's) in the n-th iterate of the mapping is given by A289004.

V3-012556 | OEIS-A289629

Smallest positive k such that (k+1)^n + (-k)^n is divisible by a square greater than 1.

Conjecture: (k+1)^n + (-k)^n is not squarefree for the following (n, k) patterns, with m >= 1: (22m-11, 2), (20m-6, 3), (20m-2, 3), (3^m, 7), (15m, 7), (20m-15, 14), (16m-8, 19), (42m-35, 23), and (8m-4, 113). In each case, the value of a(n) in this sequence is usually equal to the value specified for k, but sometimes this value is not the smallest such k. For example, in the (n, k) = (20m-2, 3) case, a(20m-2) = 3 for m = 1..3, but at m = 4, a(20*4-2) = a(78) = 1.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012588 | OEIS-A290169

a(n) = least k such that both the sum of the smallest n divisors of k and the sum of its greatest n divisors are prime numbers.

The sequence contains a subsequence of numbers having the property that the sum of the first n divisors is equal to the sum of the last n divisors; for instance, for a(n) = 2, 4, 16 and 64 with n = 2, 3, 5 and 7. Is it possible to conjecture that this subsequence contains all the superperfect numbers (A019279)? The answer is no: for instance, A019279(5) = 4096 = 2^12 => the sum of the 13 terms 1 + 2 + 4 + 8 + ... + 4096 = 8191 is a Mersenne prime, but a(13) = 800 instead 4096 > 800, and we obtain the corresponding pair of primes (293, 1933) instead (8191, 8191).

V3-012599 | OEIS-A290203

Numbers m having greatest prime power divisor d such that d is smaller than the difference between m and the largest prime smaller than m.

It is conjectured that for all integers m there exist two primes p and r such that all the binomial coefficients (m,k) with 1 <= k <= m-1 are divisible by either p or r. Using Lucas's Theorem we can prove that the conjecture is true for integers m such that the difference between m and the largest prime smaller than m is smaller than the greatest prime power divisor of m. Therefore this list examines the numbers m that do not satisfy this property.

V3-012610 | OEIS-A290290

Numbers m having greatest prime power divisor d such that d is smaller than the difference between m and the largest prime smaller than m and d is smaller than the difference between m and twice the largest prime smaller than m/2.

It is conjectured that for all integers m there exist two primes p and r such that all the binomial coefficients (m,k) with 1 <= k <= m-1 are divisible by either p or r. Using Lucas's Theorem we can prove that the conjecture is true for integers m such that the difference between m and the largest prime smaller than m is smaller than the greatest prime power divisor of m. In A290203 we examine the integers that do not satisfy this property. However, when this property is not satisfied, if the difference between m and twice the largest prime smaller than m/2 is smaller than the greatest prime power divisor of m we can prove the conjecture for odd numbers and some cases of even numbers. Note that we take the difference between m and twice the largest prime smaller than m/2 because this is the last digit of the base-p representation of m, where p refers to the largest prime smaller than m/2. Therefore, this list examines the numbers that satisfy neither of the two properties and hence are the difficult cases for the proof of the conjecture.

V3-012617 | OEIS-A290408

Decimal expansion of the real part of the solution of z = (i+z)^(-i) in C (i is the imaginary unit).

In C, the unique invariant point of the mapping M(z) = (i+z)^(-i) is not the attractor of the mapping (unstable behavior), but it is an attractor of the modified mapping M'(z) = (z+M(z))/2. For M', it takes 5000 iterations to reduce the value of |z - M'(z)| below 10^(-3400). Interestingly, the imaginary part of z seems to be equal to -1/2 (verified to 5000 digits). If this conjecture holds, and considering the definition, one can symbolically write (i+(i+(i+...)^(-i))^(-i))^(-i) = a - i/2.

V3-012631 | OEIS-A290540

Determinant of circulant matrix of order 10 with entries in the first row that are (-1)^(j-1)*Sum_{k>=0} (-1)^k*binomial(n, 10*k+j-1), for j=1..10.

A generalization. For an even N >= 2, consider the determinant of circulant matrix of order N with entries in the first row (-1)^(j-1)K_j(n), j=1..N, where K_j(n) = Sum_{k>=0} (-1)^k*binomial(n, N*k+j-1). Then it is 0 for n == N-1 (mod N). This statement follows from an easily proved identity K_j(N*t + N - 1) = (-1)^t*K_(N - j + 1)(N*t + N - 1) and a known calculation formula for the determinant of circulant matrix [Wikipedia]. Besides, it is 0 for n=1..N-2. We also conjecture that every such sequence contains infinitely many blocks of N-1 negative and N-1 positive terms separated by 0's.

V3-012633 | OEIS-A290601

Irregular triangle read by rows: T(n, k) gives the least positive integer imin such that the sequence {A290600(n, k)^i}_{i >= imin} (mod A002808(n)) is periodic.

Conjecture:There exists always an imin >= 1 such that the power sequence A290600(n, k)^i (mod A002808(n)) is periodic for i >= imin. Otherwise T(n, k) is undefined, and one could use T(n, k) = -1. See below for a proof. The above conjecture is trivially true because {K^i}_{i >= 0} (mod N) becomes (or is) always periodic (K and N positive integer). This follows from the fact that at most N values are possible, namely {0, 1, ..., N-1} and for i >= N one of these values has to appear for the second time, leading to periodicity. Thus the above sequence where gcd(N, K) is not 1 is also defined. - _Wolfdieter Lang_, Sep 05 2017

V3-012635 | OEIS-A290633

Lexicographically earliest sequence of positive integers such that, for any m and n > 0, gcd(a(n), a(n+1)) > 1 and a(n) != a(n+2), and if m < n then a(m) != a(n) or a(m+1) != a(n+1).

Conjecturally, (a(n), a(n+1)) runs over all pairs of noncoprime positive integers; in this sense, this sequence is opposite to sequences like Stern's diatomic series (A002487). This sequence has connections with A067992: here we avoid duplicate ordered pairs of consecutive terms, there unordered pairs, here we deal with noncoprime consecutive terms, there we (conjecturally) have coprime consecutive terms; also, the scatterplots of these sequences have similarities.

V3-012692 | OEIS-A291657

Primes p such that p is a primitive root modulo prime(p).

The conjecture in A291615 implies that the current sequence has infinitely many terms. In fact, if there are only finitely many primes p with p a primitive root modulo prime(p) and we let P denote the product of all such primes, then by Dirichlet's theorem there is a prime q == 1 (mod 4*P) and hence any prime p with p a primitive root modulo prime(p) is a quadratic residue modulo q and hence not a primitive root modulo q. Conjecture: a(n)/(n*log(n)) has a positive limit as n tends to the infinity. Equivalently, all the terms in this sequence form a subset of the set of all primes with positive asymptotic density.

V3-012713 | OEIS-A292217

Conjectured list of numbers in increasing order that belong to sociable cycles of length greater than 2 in which the sum of the cycle is divisible by 10.

Conjectured list of numbers in increasing order that belong to sociable cycles of length greater than 2 in which the sum of the cycle is divisible by 10. Up to the known 1593 sociable number cycles, 96.1% of the sociable number cycles satisfy this condition (up to the first 10 sociable number cycles: 40%; up to the first 100 sociable number cycles: 77%; up to the first 500 sociable number cycles: 92%, and up to the first 1000 sociable number cycles: 94.9%). So the conjecture here is that as the number of sociable number cycles increases, the percentage of the sums of the sociable number cycles divisible by 10 approaches 100%. Notice that the sums of amicable pairs are similarly often divisible by 10, but are not included here (see A291422).

V3-012730 | OEIS-A292559

Composite numbers m such that lpf(2^m - 1) == 1 (mod m).

Conjecture: there are no numbers k in this sequence such that, for each prime factor q of 2^k - 1, q == 1 (mod k). - _Thomas Ordowski_, Sep 20 2017 Note: if all prime factors q of 2^k - 1 are q == 1 (mod k), then 2^k - 1 == 1 (mod k), thus 2^k == 2 (mod k), so k is a pseudoprime. The pseudoprime k = a(42) = 4369 = 17*257 is not a counterexample to this conjecture. A pseudoprime k = P*Q such that both 2^P - 1 and 2^Q - 1 are primes would be a counterexample, but the known Mersenne primes do not give such k. - _Thomas Ordowski_, Oct 02 2017

V3-012734 | OEIS-A292726

a(n) is the number of states that can be achieved when starting from n piles each containing one stone, where any number of stones can be transferred between piles that start with the same number of stones.

Conjecture: A000041(n) - a(n) = 0 if and only if n is a power of 2, and Conjecture: A000041(n) - a(n) = 1 if and only if n is an odd prime. Consider the inverse operation: either divide an even stack in two, or replace two stacks of equal parity with their averages. The states which have no inverse moves are precisely those with all parts equal and odd. If n is a power of two, its only odd divisor is 1 and so every state can be inverted to the all-ones state, and if n is an odd prime then the only states which cannot be inverted are the all-ones state and [n]. If n has an odd divisor d with 1 < d < n, then unreachable states include the all-d's state and any state obtainable from it by combining d's in pairs, of which there is at least one. Therefore, both conjectures are true. - _Charlie Neder_, Jan 28 2019

V3-012760 | OEIS-A293142

Largest nonrepunit base-n circular prime (conjectured).

Largest nonrepunit base-n circular prime (conjectured). a(3)-a(6) were found via a brute-force approach searching from the largest prime with 12 base-n digits backwards. The number of base-n digits in a(n) for n = 3, 4, 5, 6 is 2, 5, 5, 3, respectively. Since this is much shorter than 12 digits, it is conjectured that the terms are the maximal circular primes for those bases. This also verifies that no circular primes with a length between A055642(a(n)) and 13 digits exist in bases 3, 4, 5 and 6.

V3-012796 | OEIS-A293771

Minimum number of steps needed to compute n using a machine that can read, write and add starting with the number 1.

Conjecture: reading from memory (operation 2) is never needed to get to a number in the minimal number of steps. Additional conjectures and comments by _Glen Whitney_, Oct 12 2021: (Start) Conjecture II: For each n, there is a minimal-length program for n that stores numbers in memory in increasing order. Conjecture III: For each n, there is a minimal-length program such that the difference between successive numbers stored in memory is strictly increasing. All three conjectures are empirically verified for all programs of length 23 or less, and all values of n up to 2326. However, note that if you are allowed to specify the set of numbers that must be stored in memory, then the first conjecture fails for memory {1,3,9,27,30,54} and conjecture II fails for {1,3,9,27,30,54,60}. (These sequences of numbers in memory are similar to addition chains, see A003313.) Hence, a proof of the first conjecture might need to involve showing that every n has a "good" sequence of numbers that can be stored in memory to produce n, avoiding the need to invoke the read operation. Conjecture III supplies one speculative possibility of a property that might fill the role of "good." A proof of any of these conjectures would tremendously speed up computation of a(n) as compared to brute force. (End)

V3-012801 | OEIS-A293929

Smallest number in base 10 that cannot be collapsed to a single digit using fewer than n plus signs.

Butler et al. (2016) conjectured that collapsing each term x by simply inserting a plus sign in the "middle" of the decimal expansion and adding would require in the order of log (log x) plus signs. Conjecture: Digital root for terms a(n) > 0 is 1. - _Simon Demers_ and _J. Stauduhar_, Nov 16 2017 a(n) <= ((a(n-1)-1)^2)/3 + a(n-2) for n > 1 (conjectured). This would provide a relatively tight upper bound on a(n). If the Demers-Stauduhar conjecture in the Comments turns out to be true, this upper bound will always be an integer. - _Simon Demers_, Nov 29 2017

V3-012812 | OEIS-A294185

Number of distinct lesser twin primes which are in Goldbach partitions of 2n.

Tomas Oliveira e Silva in 2012 experimentally confirmed that all even numbers <= 4*10^18 have at least one Goldbach partition (GP) with a prime 9781 or less. Detailed examination of all even numbers < 10^6 showed that the most popular prime in all GPs is 3 (78497 occurrences), then 5 (70328), then 7 (62185), then 11 (48582), then 13 (40916), then 17 (31091), then 19 (29791) -- all these primes are twin primes. These results gave rise to a hypothesis that twin primes should be rather frequent in GP, especially those relatively small.

V3-012814 | OEIS-A294203

Number of partitions of n into distinct Lucas parts (A000204) greater than 1.

Positions of 0: 1, 2, 5, 6, 8, 9, 12, 13, ... = A287775(n) - 1 (conjecture). Proof of the 'positions of 0' conjecture: let (z(n))=1,2,5,6,8,9,12,... be the positions of 0. The crucial observation is that if a number n is the sum of distinct Lucas parts greater than 1, then n+1 is a sum of Lucas parts. This implies that (z(2n))=2,6,9,13,... is the sequence of numbers A054770 that are not a sum of Lucas numbers. We see there that Ian Agol proved that b(n):=A054770(n)=floor(phi*n)+2n-1. But then the sequence of first differences (b(n+1)-b(n)) equals the Fibonacci word on the alphabet {4,3}, yielding that (z(2n)-z(2n-1)) equals the Fibonacci word on {3,2}, and we already know that z(2n+1)-z(2n)=1 for all n. On the other hand, A287775 has the same first difference sequence given by A108103. Since A287775(1)=2, the conjecture follows. (End) Positions of 1: 0, 3, 4, 10, 15, 28, 44, 75, ... = A001350(n+1) - 1 (conjecture).

V3-012851 | OEIS-A294973

Denominators of the continued fraction convergents to sqrt(7)/2.

The g.f. is correct: denominator recurrence a(n) = b(n)*a(n-1) + a(n-2), a(-1) = 0, a(0) = 1, (a(-2) = a(0) = 1) with b(n) modulo 4 from the continued fraction given above: b(0) = 1, b(4*(k+1)) = 2, b(4*k+1) = 3 = b(4*k+3) and b(4*k+2) = 10, for k >= 0. The 4-section is G(x) = Sum_{k>=0} a(k)*x^k = G_0(x^4) + x*G_1(x^4) + x^2*G_2(x^4) + x^3*G_3(x^4) with G_j(x) = Sum_{k>=0} a(4*k+j)*x^k, for j=0..3. The recurrence leads to four equations (omit the x here): G_1 = 3*G_0 + x*G_3, G_2 = 10*G_1 + G_4, G_3 = 3*G_2 + G_1, G_0 = 2*x*G_3 +1 + x*G_2 (using a(-2) = 1). This can be solved to obtain for G(x) = (1 + 3*x + 31*x^2 + 96*x^3 - 31*x^4 + 3*x^5 - x^6)/(1 - 254*x^4 + x^8), and the numerator and denominator factorize like given in the above conjecture. - _Wolfdieter Lang_, Nov 19 2017

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-012863 | OEIS-A295196

Numbers n > 1 such that 2^(n-1) and (2*n-m)*2^(((n-1)/2) - floor(log_2(n))) are congruent to 1 (mod n) for at least one of m = 3, m = 7 and m = 15.

This definition arises from the conjecture that pseudoprime numbers (A001567) occur only at certain distances m from the next smaller number of the form 2^n. So, if we know that a certain distance does not appear with pseudoprime numbers, we are able to calculate these numbers using Fermat's little theorem and we know that it has to be prime. To "plot" the distance of pseudoprime numbers to 2^n use m = A001567(n) - 2^floor(log_2(A001567(n))). So, the first values of m which do not have a "safe prime number distance" (values with "safe prime number distance" are those values for m which pseudoprime numbers never have) should be m = 1, 49, 81, 85, 129, 133, 273, 275, 289, 321, ... Conjecture 1: There are no composite numbers in this sequence and perhaps infinitely many primes. Conjecture 2: For m = 7 this definition generates A104066 and for m = 15 this definition generates A144487 (A057197). Conjecture 3: There are (infinitely many?) m for which this definition generates nothing but (infinitely many?) primes of the form p = 2^k + m.

V3-012871 | OEIS-A295339

Least k for the inner Theodorus spiral to complete n revolutions.

Conjecture: a(n) = A072895(n) - 2, n >= 1. This follows from the conjecture that the sequences K := {floor(phi(k)/(2*Pi)}_{k >= 1} with phi given above, and Khat:= {floor(phihat(k)/(2*Pi)}_{k >= 1} with phihat given above satisfy Khat(k-2) = K(k), for k >= 3. Note that phihat(k-2) - phi(k) = alpha(k-2) - alpha(k-1) =: delta(k) = arctan((sqrt(k-1) - sqrt(k-2))/(1 + sqrt((k-1)*(k-2)))) > 0, for k >= 3. Therefore the conjecture is that delta(k) < 2*Pi*(1 - frac(phi(k)/(2*Pi))), for k >= 3, or, equivalently, phihat(k-2) < 2*Pi*(K(k) + 1), for k >= 3. Conjecture: a(n) = A072895(n) - 2, n >= 1 (see the comment above).

V3-012874 | OEIS-A295424

Number of distinct twin primes which are in Goldbach partitions of 2n.

Tomas Oliveira e Silva in 2012 experimentally confirmed that all even numbers 4 <= n <= 4 * 10^18 have at least one Goldbach partition (GP) with a prime 9781 or less.

Detailed examination of all even numbers less than 10^6 showed that the most popular prime in all GPs is 3 (78497 occurrences), then 5 (70328), then 7 (62185), then 11 (48582), then 13 (40916), then 17 (31091), then 19 (29791) -- all these primes are twin primes. These results gave rise to a hypothesis that twin primes should be rather frequent in GP, especially those relatively small. Conjecture. Further empirical examinations lead to a hypothesis that all even numbers n > 4 have at least 1 twin prime in GP(n).

V3-012875 | OEIS-A295431

a(n) = (12*n)!*n! / ((6*n)!*(4*n)!*(3*n)!).

Conjectures: 5*7*11*a(n)/(n + 1), 5*a(n)/(2*n + 1), a(n)/(3*n + 1) and 2*5*7*11*a(n)/((n + 1)*(2*n + 1)*(3*n + 1)) are integers for all n (checked up to n = 1000). It appears that a(n)/(12*n - 1) is integral for all n (checked up to n = 1000). More generally, for r >= 1, we conjecture that there exists a constant D(r) > 0 such that D(r)*a(n)/Product_{i = 1..r, i coprime to 12} (12*n - i) is integral for all n. For n >= 0, we conjecture that both a(n/2) = (6*n)!*(n/2)! / ((3*n)!*(2*n)!*(3*n/2)!) = A347854(n) and a(n/3) = (4*n)!*(n/3)! / ((2*n)!*(4*n/3)!*n!) = A347855(n) are integers, where fractional factorials are defined using the Gamma function; for example, (n/2)! := Gamma(n/2 + 1). - _Peter Bala_, Jun 09 2026

V3-012881 | OEIS-A295741

a(n) is smallest divisor d of the n-th primorial such that d + prime(n)#/d is prime.

Conjecture: a(n) < prime(n)^2 for n > 0. Reo Fortune conjectured that the smallest integer q such that primorial(n) + q is prime, is again a prime: see A005235. This conjecture is still unproven. For this sequence here as well, it is unproven that a(n) always exists. Of course it is trivial that a(n)^2 < prime(n)#, and a(n) must be a squarefree product of primes less than prime(n), if it exists. - _M. F. Hasler_, Apr 11 2026 Conjecture: a(n) < prime(n) for n > 0. - _Alain Rocchelli_, Aug 31 2026 Conjecture: Limit_{N->oo} (Sum_{n=1..N} a(n)) / (Sum_{n=1..N} prime(n)) = 0. - _Alain Rocchelli_, Aug 30 2026

V3-012887 | OEIS-A295928

Number of triangular matrices T(n,i,k), k <= i <= n, with entries "0" or "1" with the property that each triple {T(n,i,k), T(n,i,k+1), T(n,i-1,k)} containing a single "0" can be successively replaced by {1, 1, 1} until finally no "0" entry remains.

The algorithm for the sequence is rather slow because each start matrix is constructed separately. There exists a faster recursive algorithm which produces the same terms and therefore is likely to be correct, but it is based on a conjecture. For the theory of the recurrence, see "Recursive aspects of fill matrices". Probable extension a(10)-a(14):

821096828, 15804092592, 324709899276, 7081361097108, 163179784397820.

V3-012894 | OEIS-A296181

First point of the discrete Theodorus spiral in the fourth quadrant for the n-th revolution, for n >= 1.

This sequence is used in a conjecture on points z_k of the discrete (outer) Theodorus spiral living on quadrant IV of the complex plane of sheet S_n, where S_n := {r*exp(i*phi), r > 0, 2*Pi*(n-1) <= phi < 2*Pi*n}. This corresponds to the n-th revolution, for n >= 1. This conjecture is 2*Pi - varphi(A072895(n)) > arctan(a(n)), n >= 1, with varphi(k) = phi(k) - 2*Pi*floor(phi(k)/(2*Pi)) where z_k = sqrt(k)*exp(i*phi(k)). This conjecture implies a conjecture relating points of the discrete inner spiral to those of the outer ones, namely Khat(k-2) := floor(phihat(k-2)/(2*Pi)) = K(k) =: floor(phi(k)/(2*Pi)) for k >= 3, where zhat_k = sqrt(k)*exp(i*phihat(k)) is a point of the discrete inner Theodorus spiral, given in terms of z_k by zhat(k) = ((k-1 + 2*sqrt(k)*i)/(k+1))*z_k. This implies phihat(k) = phi(k) + arctan((sqrt(k-1) - sqrt(k-2))/(1 + sqrt((k-1)*(k-2)))). The implied conjecture Khat(k-2) = K(k), k >= 3, for the other three quadrants of each sheet S_n can be proved. For the inner spiral see the Waldvogel link. If the implied conjecture is true then A295339(n) = A072895(n) - 2, for n >= 1, hence A296179(n) = A295338(n), for n >= 2. For the conjecture and the proof for the first three quadrants for each sheet S_n see the W. Lang link. - _Wolfdieter Lang_, Jan 24 2018

V3-012907 | OEIS-A296524

Number of connected (2*k)-regular graphs on 2*n+1 nodes with maximal diameter D(n,k) A294733 written as triangular array T(n,k), 1 <= k <= n.

The next term a(24) corresponding to the 6-regular graphs on 15 nodes is conjectured to be 1. It seems that there exists only one graph with diameter A294733(24)=4. Its adjacency matrix is The conjecture is confirmed using Markus Meringer's GenReg program. Aside from the 1 shown 6-regular graph on 15 nodes with diameter 4 there are 870618932 graphs with diameter 2 and 599674742 graphs with diameter 3. - _Hugo Pfoertner_, Dec 19 2017

V3-012916 | OEIS-A297195

Number of bitriangular permutations (row sums of A272644 if that triangle is prefixed with two rows for n=0,1).

Define c(n) = Sum_{m=2..n-1} C(n-1, m-1)^(-2). Define b(1) = x and b(n+1) = b(n) + (Sum_{m=2..n-1} b(m)*b(n+1-m)*C(n-1, m-1)^(-2))/n^2 for n>0. Then b(n) is a polynomial in x and so is (b(n+1)-b(n))/x^2 whose constant term is c(n)/n^2. The Hone et al. (2002) link denotes x with alpha_2 and alpha_k = (k-1)!^2*b(k). Conjecture: Asymptotic expansion of c(n) = 2*Sum_{i>1} a(i)/n^i. - _Michael Somos_, Oct 17 2024

V3-013007 | OEIS-A299154

a(n) is the distance from prime(n) to the next prime that has the same digital root, or a(n) = 0 if there is no greater prime with the same digital root.

I conjecture that there are infinitely many prime numbers with each of the digital roots from the set {1,2,4,5,7,8}. This would imply that the only prime number with a(n) = 0 is 3. The conjecture is true; for any d in {1,2,4,5,7,8}, gcd(d, 9) = 1, hence, according to Dirichlet's theorem on arithmetic progressions, there are infinitely many primes of the form d + 9*k, and these primes all have digital root d. - _Rémy Sigrist_, Mar 25 2018

Number of ways to write n^2 as x^2 + y^2 + z^2 + w^2 with x >= y >= 0 <= z <= w such that x or 2*y is a power of 4 (including 4^0 = 1) and x + 15*y is also a power of 4.

Conjecture 1: a(n) > 0 for all n > 0. Also, for any integer n > 1 we can write n^2 as x^2 + y^2 + z^2 + w^2 with x >= y >= 0 <= z <= w such that 2*x or y is a power of 4 and also x + 15*y = 2^(2k+1) for some k = 0,1,2,.... Conjecture 2: Let d be 2 or 8, and let r be 0 or 1. Then any positive square n^2 can be written as x^2 + y^2 + z^2 + w^2 with x,y,z,w nonnegative integers such that x or y is a power of 2 and x + d*y = 2^(2k+r) for some k = 0,1,2,.... We have verified Conjecture 1 for n up to 10^7. See also A299537, A300219 and A300396 for similar conjectures.

V3-013034 | OEIS-A299898

Coordination sequence for "ftu" 3D tiling with respect to first type of node.

The following is a conjectured recurrence, found by gfun, using the command rec:=gfun[listtorec](t1, a(n)); (where t1 is a list of the initial terms) suggested by _Paul Zimmermann_. Conjectured g.f.: (-x^21 - 3*x^20 - 5*x^19 - 8*x^18 - 13*x^17 - 18*x^16 - 22*x^15 - 27*x^14 - 32*x^13 - 35*x^12 - 36*x^11 - 36*x^10 - 35*x^9 - 32*x^8 - 27*x^7 - 22*x^6 - 17*x^5 - 11*x^4 - 7*x^3 - 5*x^2 - 3*x - 1) / ((x - 1)^3*(1 + x + x^2)*(1 + x^4)*(1 + x^3 + x^6)*(1 + x + x^2 + x^3 + x^4 + x^5 + x^6)). Conjecture: a(n) = 11/7*n^2 - 13/63*n + 31/42 + (((3*n^2+3*n+1) mod 7) + (n mod 7) + ((n+1) mod 7) - ((n+2) mod 7) - ((n+4) mod 7))/7 + ((n^2+n+2) mod 4) + (4*((n+5) mod 8) + 3*((n+4) mod 8) - 4*((n+7) mod 8) - 3*(n mod 8))/8 + (((7*n+4) mod 9) + 2*(n mod 9) + ((n+1) mod 9) + ((n+2) mod 9) - ((n+3) mod 9) - 2*((n+4) mod 9) - 2*((n+5) mod 9) + ((n+8) mod 9))/9 - [n = 0]. (End)

V3-013035 | OEIS-A299900

Coordination sequence for "ftu" 3D tiling with respect to second type of node.

I have to say that I am not very confident about the conjectured g.f. below. We only have 128 terms, and the recurrence has 57 or so coefficients and 57 or so initial terms, and 114 is pretty close to 128. So not much of a safety margin. If the same g.f. still holds when we get 500 terms I will believe it. - _N. J. A. Sloane_, Jan 03 2021 This empirically corroborates the conjectured generating function/recurrence above to the 500-term margin requested in the 2021 comment by _N. J. A. Sloane_. The submitted 501-term table supplies the requested margin. The terms were computed independently from the RCSR CGD description of the ftu net: expanding the Fm-3m symmetry gives a translation-labeled quotient graph with 288 vertices and 576 undirected edges, every vertex of degree 4. The same quotient graph gives A299898 from node type 1 (root vertex 0), agreeing with its existing b-file, and gives this sequence from node type 2 (root vertex 192). The first 128 A299900 terms agree with the existing b-file, and the extension through n = 500 agrees with the proposed rational generating function P(x)/Q(x). The leading growth term in the conjectured formula is (11/7)*n^2. Although Q has quasi-polynomial period 1008, only the constant coefficient has full period 1008; the n^2 coefficient is constant and the n coefficient has period 12. The following is a conjectured recurrence, found by gfun, using the command rec:=gfun[listtorec](t1, a(n)); (where t1 is a list of

the initial terms) suggested by _Paul Zimmermann_. Conjectured g.f., empirically corroborated by the 501-term table below: A(x) = P(x)/Q(x), where P and Q are given in the linked PARI and Python programs as coefficient lists in ascending powers of x. The corresponding degree-53 recurrence from Q is satisfied by the 501-term table for n = 58..500. For this conjectured g.f. the quasi-polynomial form is a(n) = (11/7)*n^2 + b(n mod 12)*n + c(n mod 1008), for n >= 5, where b = [-58/63, -389/504, -52/63, -443/504, -46/63, -437/504, -58/63, -347/504, -52/63, -485/504, -46/63, -395/504]. The constant coefficient c has period 1008.

V3-013044 | OEIS-A300012

A permutation of the positive integers in which adjacent terms differ by a single prime factor and a(n) has no prime factor exceeding prime(n), having the lexicographically earliest inverse.

This permutation can be viewed as a tour of the positive integers, multiplying or dividing by a prime at each step. The "lexicographically earliest inverse" condition means no other such tour visits an integer k earlier, unless it visits an integer less than k later than this tour does (but see the proviso addressed by conjectures 1 and 2 below). The condition "a(n) has no prime factor exceeding prime(n)" is included to ensure the sequence is well-defined. The author anticipates the condition may be redundant, in the sense that if it is removed: (conjecture 1) the lexicographically earliest inverse remains defined; and (conjecture 2) the terms remain the same. Conjecture: A006530(a(n)) <= n; lim sup A006530(a(n))/n < 0.4. (End)

V3-013051 | OEIS-A300356

Number of ways to write n^2 as x^2 + y^2 + z^2 + w^2 with x >= y >= 0 <= z <= w such that x + 63*y = 2^(2k+1) for some nonnegative integer k.

Conjecture: (i) a(n) > 0 for all n > 1, and a(n) = 1 only for n = 5, 13, 25, 29, 59, 61, 91, 95, 101, 103, 211, 247, 2^k (k = 1,2,...), 4^k*79 (k = 0,1,2,...), 2^(2k+1)*m (k = 0,1,2,... and m = 3, 5, 7, 11, 15, 19, 23). See also A299924 and A300219 for similar conjectures.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Mar 03 2018 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013052 | OEIS-A300360

Number of ways to write n^2 as x^2 + y^2 + z^2 + w^2 with x,y,z,w nonnegative integers and z <= w such that x or y is a power of 2 (including 1) and x + 63*y = 2^(2k+1) for some k = 0,1,2,....

Conjecture: a(n) > 0 for all n > 1, and a(n) = 1 only for n = 5, 13, 25, 29, 59, 61, 79, 91, 95, 101, 103, 1315, 2^k (k = 1,2,3,...), 2^(2k+1)*m (k = 0,1,2,... and m = 3, 5, 7, 11, 15, 19, 23). In the comments of A300219, the author conjectured that a positive square n^2 can be written as x^2 + y^2 + z^2 + w^2 with x,y,z,w nonnegative integers such that both x and x + 3*y are powers of 4 unless n has the form 4^k*81503 with k a nonnegative integer. Since 81503^2 = 208^2 + 16^2 + 51167^2 + 63440^2 with 16 = 4^2 and 208 + 3*16 = 4^4, this implies that any positive square can be written as x^2 + y^2 + z^2 + w^2 with x,y,z,w nonnegative integers such that x or y is a power of 4 and x + 3y is also a power of 4. We also conjecture that for any positive integer n not of the form 4^k*m (k =0,1,... and m = 2, 7) we can write n^2 as x^2 + y^2 + z^2 + w^2 with x,y,z,w nonnegative integers such that x or y is a power of 4 and x + 2*y is also a power of 4.

V3-013061 | OEIS-A300448

Number of the integers 4^k*m with k >= 0 and m = 1, 2, 5 such that n^2 - 4^k*m can be written as the sum of two squares.

Conjecture 1: a(n) > 0 for all n > 0. Conjecture 2: Each positive square n^2 can be written as 4^k*m + x^2 + y^2 with k,x,y nonnegative integers and m among 1, 5 17. Conjecture 3: For each n = 1,2,3,... we can write n^2 as 4^k*m + x^2 + y^2 with k,x,y nonnegative integers and m among 1, 5, 65. Conjecture 3 implies that A300441(n) > 0 for all n > 0 since 4*A001353(0)^2 + 1 = 1, 4*A001353(1)^2 + 1 = 5 and 4*A001353(2)^2 + 1 = 65. We have verified Conjectures 1-3 for all n = 1..2*10^7.

V3-013062 | OEIS-A300510

Number of ways to write n^2 as 4^k*(m^2+1) + x^2 + y^2, where m is 1 or 2, and k,x,y are nonnegative integers with x <= y.

Conjecture: a(n) > 0 for all n > 1; in other words, for any integer n > 1 there is a nonnegative integer k such that either n^2 - 2*4^k or n^2 - 5*4^k can be written as the sum of two squares. Moreover, a(n) = 1 only for n = 2^k with k > 0. This conjecture is stronger than the first conjecture in A300448. We have verified that a(n) > 0 for all n = 2..5*10^7.

V3-013063 | OEIS-A300531

Matching number of the n-polygon diagonal intersection graph.

Conjecturally, a matching exists for every n with at most one unmatched vertex. This would imply a(n) = floor(A007569(n)/2). A computer search, using a simple nonbacktracking algorithm, has shown the existence of such matchings up to n = 22 and indeed for small n there are large numbers of maximum matchings (A292921). Such a matching could also be constructed from a Hamiltonian path (A300551) by selecting every other edge, so a proof that these graphs are Hamiltonian would also suffice. - _Andrew Howroyd_, Mar 12 2018

V3-013088 | OEIS-A300949

Carmichael numbers whose prime factors form an arithmetic progression.

Conjecture: if n is a Carmichael number and lpf(n)gpf(n)(lpf(n)+gpf(n))/2 = n, then (lpf(n)+gpf(n))/2 is prime; and thus n has exactly three prime factors. Such numbers n form a proper subsequence of this sequence, also subsequence of A262723. - _Charles R Greathouse IV_ and _Thomas Ordowski_, Mar 17 2018. Edited by _Max Alekseyev_, Mar 17 2018 Proof of the above conjecture: Say n = paq with 2 < p < q being primes and a = (p+q)/2, with (a,p!)=1. If n is a Carmichael number, then pa == 1 (mod q-1), so p^2 + pq == 2 (mod q-1), so p^2 + p == 2 (mod q-1). In particular, p^2 + p - 2 >= q-1, which implies that (p+1)^2 > q. Say a has k prime factors, so that a >= (p+2)^k. But a < q, so q > (p+2)^k. Thus, (p+1)^2 > q > (p+2)^k. This implies k=1. - Carl Pomerance (in a letter to the second author), Mar 18 2018

V3-013089 | OEIS-A300984

Numbers whose sum of squarefree divisors and sum of nonsquarefree divisors are both squarefree numbers.

Conjecture: a(n) is of the form a(n) = 2^i*p^j with i, j integers and p prime. This has been verified for n up to 10^7. Generalization: For n <= 10^m with m > 7, it is conjectured that a majority of primes p where a(n) = 2^i*p^j are in A082539. For example, with m = 7, 84% of the primes p are in A082539.

V3-013107 | OEIS-A301471

Number of ways to write n^2 as x^2 + 2*y^2 + 3*2^z with x,y,z nonnegative integers.

Square Conjecture: a(n) > 0 for all n > 1. Moreover, for any integer n > 3 we can write n^2 as x^2 + 2*y^2 + 3*2^z, where x,y,z are nonnegative integers with y even and z > 1. The Square Conjecture implies that for each n = 1,2,3,... we can write 3*n^2 as x^2 + 2*y^2 + 2^z with x,y,z nonnegative integers. In fact, if (3*n)^2 = u^2 + 2*v^2 + 3*2^z with u,v,z integers and z >= 0, then u^2 == v^2 (mod 3) and thus we may assume u == v (mod 3) without loss of generality, hence 3*n^2 = (u^2+2*v^2)/3 + 2^z = x^2 + 2*y^2 + 2^z with x = (u+2*v)/3 and y = (u-v)/3 integers. On March 25, 2018 Qing-Hu Hou at Tianjin Univ. finished his verification of the Square Conjecture for n <= 4*10^8. Then I used Hou's program to verify the conjecture for n <= 5*10^9. - _Zhi-Wei Sun_, Apr 10 2018 I have found a counterexample to the Square Conjecture, namely a(5884015571) = 0. Note that 5884015571 is the product of the three primes 7, 17 and 49445509. - _Zhi-Wei Sun_, Apr 15 2018

V3-013126 | OEIS-A301719

Partial sums of A301718.

Conjecture: a(n) ~ 14*n^2/5. - _Stefano Spezia_, Mar 28 2023

猜想/问题提及段 | historical_or_current_mention_unreviewed | _N. J. A. Sloane_, Mar 26 2018 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013127 | OEIS-A301743

Lexicographically first sequence with no duplicate term whose digits' concatenation is the same as the digits' concatenation of all sums of adjacent terms lined up one by one.

This sequence is conjectured to be a permutation of A000027 (the positive numbers).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Eric Angelini_ and _Jean-Marc Falcoz_, Mar 26 2018 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013128 | OEIS-A301746

Expansion of Product_{k>=1} (1 + x^k)^(sigma_0(k)^2).

Conjecture: log(a(n)) ~ sqrt(n) * log(n)^(3/2) / (2*sqrt(6)). - _Vaclav Kotesovec_, Aug 29 2018

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Vaclav Kotesovec_, Mar 26 2018 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013129 | OEIS-A301757

Positive determinant values assumed by performing all permutations of entries in the 3 X 3 matrix of A301372.

A 3 X 3 matrix with given 9 matrix entries can produce A088021(3)=10080 distinct determinants if all positional permutations are performed. The current sequence provides the 5040 positive determinants of a conjectured optimal matrix minimizing its greatest matrix entry.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013132 | OEIS-A301807

Lexicographically first sequence of distinct integers whose concatenation of digits is the same as the concatenation of the digits of the absolute differences between consecutive terms.

In fact, a(18420) = 42; however that this sequence is a permutation of the natural numbers remains an open question.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Eric Angelini_ and _Jean-Marc Falcoz_, Mar 27 2018 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013133 | OEIS-A301858

Positive integers which can be written as the sum of two squares but cannot be written as x^2 + y^2 + 2*z^2 with x and y integers and z a nonzero integer.

Conjecture 1: The sequence only has the four terms 1, 5, 29 and 65. Conjecture 2: For any integer n > 1 which is neither 17 nor a power of 2, if n = u^2 + 2*v^2 for some integers u and v, then n = x^2 + 2*y^2 + 3*z^2 for some integers x,y,z with z nonzero. Conjecture 3: For any positive integer n not of the form 4^k*m (k = 0,1,2,... and m = 1, 7, 13), if n = u^2 + 3*v^2 for some integers u and v, then n = x^2 + 2*y^2 + 3*z^2 for some integers x,y,z with y nonzero.

V3-013165 | OEIS-A302607

a(n) is the greatest possible least prime in any partition of prime(n) into three primes; n >= 4.

Goldbach's weak (ternary) conjecture states that every odd number > 5 can be expressed as the sum of three primes (see link). This sequence applies the conjecture (now proved) to primes > 5. From all possible partitions of prime(n) = p+q+r for primes p,q,r (p <= q <= r), a(n) is chosen to be the maximum possible value of the least prime p. The sequence is not strictly increasing, and although many primes are repeated, some do not appear at all (e.g., 37 and 47 are not included).

V3-013202 | OEIS-A303543

Number of ways to write n as a^2 + b^2 + C(k) + C(m) with 0 <= a <= b and 0 < k <= m, where C(k) denotes the Catalan number binomial(2k,k)/(k+1).

Conjecture: a(n) > 0 for all n > 1. In other words, any integer n > 1 can be written as the sum of two squares and two Catalan numbers. This is similar to the author's conjecture in A303540. It has been verified that a(n) > 0 for all n = 2..10^9.

V3-013203 | OEIS-A303562

G.f. A(x) satisfies: 0 = [x^(n-1)] 1 / A(x)^(n^2+n-1) for n>2.

a(n) is odd iff n = (4^k - 1)/3 for k >= 0 (conjecture).

V3-013204 | OEIS-A303595

Index of n-th prime in A294994, or -1 if that prime is missing.

Conjectured to be a permutation of the natural numbers.

V3-013205 | OEIS-A303601

Number of ways to write n as a*(a+1)/2 + b*(b+1)/2 + Bell(k) + Bell(m) with 0 <= a <= b and 0 < k <= m, where Bell(k) denotes the k-th Bell number A000110(k).

Conjecture: a(n) > 0 for all n > 1. In other words, any integer n > 1 can be expressed as the sum of two triangular numbers and two Bell numbers. See also A303389, A303540, A303543 and A303637 for similar conjectures.

V3-013206 | OEIS-A303637

Number of ways to write n as x^2 + y^2 + 2^z + 5*2^w, where x,y,z,w are nonnegative integers with x <= y.

Conjecture: a(n) > 0 for all n > 5. Jiao-Min Lin (a student at Nanjing University) found a counterexample to the conjecture: a(18836421387) = 0. - _Zhi-Wei Sun_, Jul 21 2022

V3-013207 | OEIS-A303647

a(n) = ceiling(a(n-1)/(2^(1/3)-1)+1), a(1)=1.

a(n) = A301483(n+2) - A195350(n+2) + A195339(n-3) for n > 2 (conjectured). [Corrected by _Qiyuan Gu_, Sep 18 2026] Conjectures from _Colin Barker_, Apr 28 2018: (Start)

V3-013208 | OEIS-A303691

a(n) is the number of 3-smooth numbers k such that prime(n)-k is also a prime number, where prime(n) stands for the n-th prime.

Conjecture: a(n)>0 for all n>1.
