The sequence here: http://oeis.org/A002853 tells us the maximum number of lines that can be placed in d dimensional space in a way that any pair of lines has the same angle as any other pair and all of them pass through the origin. In general, there can be multiple configurations with n lines that satisfy this property. For example, when $d=3$ and we want to place 3 lines, we can have the coordinate system (x, y and z axes) or three lines at $3 \pi/2$ radians restricted to a plane. So, there are at least two such configurations. I conjecture that when we have the maximum possible number of lines, there will be only one configuration possible. Is it possible to prove this conjecture or refute with counter-example? Related: Number of configurations of lines in d dimensional space where any pair of them have the same angle. How to draw six lines in 3-d space such that angle between any pair of them is the same.

What is known about this extension of the Erdös-Strauss-conjecture?

The Erdös-Strauss conjecture states that $$\frac{4}{n}=\frac{1}{a}+\frac{1}{b}+\frac{1}{c}$$ has a solution in positive integers for every integer $n>1$. What is known about this extension : The equation $$\frac{k}{n}=\frac{1}{a}+\frac{1}{b}+\frac{1}{c}$$ with $k=5,6$ or 7 and any integer $n\ge 3$ has a solution in positive integers. In the case $k=5$, I worked out that a counterexample is only possible, if n is of the form $20l+1$ and in this case, the conjecure holds upto $n\le 2\cdot 10^6$. I neither found counterexamples for $k=6$ and $k=7$. $k=8$ is no more possible , since $\frac{8}{11}$ has not a representation of the desired form. What is known about this extension ? Any ideas or references ?

Proving formula about the least number n such that $a|n$ and $b|(n+1)$, a,b coprime.

I have been looking for theorems that say something about relations of factors between consecutive numbers. With Bezout's identity it can be proved that if $\gcd(a,b)=1$ there is always a number n such that $a|n$ and $b|(n+1)$, which tells something about independency between factors of consecutive numbers. After a lot of work I found a simple formula that seems to determine the least non-negative number n as above, $n=b\cdot r^{-1}-1$, where r^{-1} is the number corresponding to the inverse of r in the multiplicative group of numbers coprime to a and r is the reminder when b is divided with a. Obviously $b|(n+1)$ but how to prove that $a|n$ and that there are no smaller number than n?

Prime Algorithim Conjecture

Let g be the greatest factor of a positive integer(a) where $g \neq a$ and l be the smallest factor such that $gl = a$. Let t_i be the ith term of the sequence where the starting term is $\frac{g_1!}{(a_1)^n}$ and n is the greatest positive integer such that $(a_i)^n|g_i!$. More specifically the sequence/recursive algorithim $t_i = \frac{g_{i}! }{(t_{i - 1})^n}$ For example, when a_1 is 10: $t_1 = \frac{5!}{10^n}$ Here $n = 1$, so $t_1 = \frac{5!}{10} \implies t_1 = 12$ Then $t_2 = \frac{6!}{12^n}$ In which we find $n = 2$, giving $t_2 = \frac{6!}{144} \implies t_2 = 5$ So here the sequence stops, as t_2 is prime and $g \neq a$. Its interesting to note that n is the number of pairs of the form $a = mn$ where m and n are factors of a. Now take a look at the number where a_1 is 14, $t_1=7!/141 \implies t_1 = 360 \implies t_2=180!/360^n$ You'll notice the explosive growth that it exhibits when put into the algorithm. This makes it seem skeptical this algorithm will always end at a prime number but consider the following: Lets say we have a number $t_{i -1}$ with over 10 factors after the fraction cancels out and each one has a very large prime factorization with many distinct primes in each. Now note that the prime factorization of each factor allows us to spread the primes across the other factors and combine them in many different ways. Lets say we had a function called $F(x)$ that determines the number of factors that can be possibly made from t_{i-1}. Then if we could prove that $F(x)$ at no point contains more than y of $g_i!$ factors($G(x)$) such that $t_{i} > t_{i - 1}$ than there will be numbers of a_{1} in which the algorithm will fail. But on the other hand if it does, and it can be proven that for some a_{i} for any a_1 $F(x) > \frac{G(x)}{y}$ (In this case $t_{i} < t_{i - 1}$ is true) than the algorithm can still end with a prime. Note that every consecutive term is co-prime and that we consider that a sequence terminates when t_i is prime. Given any value of g and l, where a_i is not a perfect square, this algorithm always terminates. Prove or disprove this.

The 'inscribed-circumscribed' 6 point circle

Here is a construction I came upon recently: A'B'C' is the contact triangle. X(1) is the Incenter. A'',B'',C'' are the midpoints of the sides of the contact triangle. A''',B''',C''' are the midpoints of the segments AX(1), BX(1), CX(1). Then quadrilaterals A''A'''C''C''', B''B'''C''C''', A''A'''B''B''' are cyclic. Let Ob, Oa, Oc be the circumcenters of these 3 quadrilaterals. Finally by drawing circles with centers at Oa, Ob, Oc and passing through the incenter we get the 'inscribed-circumscribed' six point circle with its center at the midpoint of X(1) and X(3) - the point X(1385) in the ETC: There is an even easier way to get a smaller concentric six point circle: circumcircles of the quadrilaterals A''A'''C''C''', B''B'''C''C''', A''A'''B''B''' cut the sides of the triangle ABC at six concyclic points. The mere fact that the point X(1385) is already

described in the ETC supposedly makes the construction not particularly inspiring for a geometer. However as this 'X(1385)-circle' has never been previously mentioned (?) in the literature, there might still be a chance that it has some 'nice' properties of its own. Specifically I am interested whether any Kimberling center belongs to this 'inscribed-circumscribed' circle? Or, alternatively, does its central function correspond to any known center?

Does Diophantine equation $1+n+n^2+\dots+n^k=2m^2$ have a solution for $n,k \geq 2$?

When studying properties of perfect numbers (specifically this post), I ran into the Diophantine equation $$ 1+n+n^2+\dots+n^k=2m^2, n\geq 2, k \geq 2. $$ Searching in range $n \leq 10^6$, $k \leq 10^2$ yields no solution. So I wonder if there are any solutions, and if not, is there some elementary reason for that? Or if it can be converted to some known open problem, that would do too... Some thoughts: Of course if we allow $n=1$ or $k=1$ we could get trivial solutions. We can also see by mod 2 that both n and k must be odd. Now we could try to solve some small cases such as $k=3$ or $k=5$... So set $k=3$ and try to solve $$1+n+n^2+n^3=2m^2.$$ Left side factors and hence we want to solve $(n+1)(n^2+1)=2m^2$. Now this imples $4 \mid 2m^2$ and so m is even. Also we can see that $4 \nmid n^2+1$ for any integer n (becase $n^2\equiv 0,1 \pmod 4 $). So all powers of 2 in $2m^2$ except one will divide $n+1$. So let $m=2^t r$ with $2 \nmid r$, then $2m^2=2^{2t+1}r^2$, $2^{2t} \mid n+1$, $2 \mid n^2+1$. So we can put $n=2^{2t}s-1$ with $2 \nmid s$, substitute it back, divide all powers of 2 and we have the equation $$ s(2^{4t-1}s^2-2^{2t}s+1)=r^2. $$ Now the two expressions in the product are coprime, so they both have to be square, and that is farthest I got so far. Also the expression $2^{4t-1}s^2-2^{2t}s+1$ being square has a solution $s=15,t=2$, and I am yet to find another (but of course s is not a square in this case so it does nothing for the original problem).

$p = (u + v)^2 + uv$ for primes $p = 5k \pm 1$?

I came up with the following conjecture which I am unable to prove. For all primes p which can be represented as either $5k + 1$ or $5k - 1$ for some positive integer k, we can find positive integers u, v such that $p = (u + v)^2 + u \times v$ For example, $31 = 5 \times 6 + 1 = (2 + 3)^2 + 2 \times 3$ Using a computer, I have verified it for $p < 10000$. Is there a general proof for this?

On a possible proof for $p^k < m$, if $p^k m^2$ is an odd perfect number with special prime p

Let $\sigma(x)=\sigma_1(x)$ denote the classical sum of divisors of the positive integer x. If $\sigma(M)=2M$ and M is odd, then M is called an odd perfect number (hereinafter abbreviated as OPN). It is currently unknown if there are any OPNs. Euler proved that a hypothetical OPN, if one exists, must have the so-called Eulerian form $$M = p^k m^2$$ where p is the special/Euler prime satisfying $p \equiv k \equiv 1 \pmod 4$ and $\gcd(p,m)=1$. Dris conjectured in his M. Sc. thesis that $p^k < m$ always holds for an OPN M given in Eulerian form. Consider the following "proof argument" for $p^k < m$: Let $M = p^k m^2$ be an OPN given in Eulerian form. Suppose that we have $m^2 < 5p^k$. Then we have $$\Bigg(m^2 < 5p^k\Bigg) \iff \Bigg(\frac{m^2}{p^k} < 5 \leq p^k\Bigg) \implies \Bigg(m^2 < p^{2k}\Bigg) \iff \Bigg(m < p^k\Bigg).$$ However, in the paper titled Improving the Chen and Chen result for odd perfect numbers, Broughan et al. show that $\sigma(m^2)/p^k \geq 315$. This implies that $$\frac{p^k}{m^2} < \frac{2}{315},$$ which contradicts $$\frac{1}{5} < \frac{p^k}{m^2}.$$ Here is my question: Does this "proof" indeed show that $p^k < m$ holds? If it does not, can it be mended so as to produce a valid argument?

This is a conjecture, refined through previous responses, about sums of positive integers which define sums of the corresponding cubes.

Revising 4255316, the conjecture now is: If $$\sum_{i=1}^{i=n}{a_{i}}, i>2$$, divides $$3\sum{x_{i}x_{j}x_{k}}$$, where the product is summed over the$\binom{n}{3}$distinct triplets drawn from the n suffices, then $$\sum_{y=0}^{y=a}\sum_{i=1}^{i=n}{x_{i}+2yb}$$ divides $$\sum_{y=0}^{y=a}\sum_{i=1}^{i=n}{(x_{i}+2yb)^{3}}$$

Maximum degree for this set of planar graphs where all neighbours of any point lie on a circle centered on that point

Consider an undirected simple planar graph, with these additional restrictions: The plane in which the graph is embedded has a Cartesian coordinate system, and there's an injective function mapping each node to its pair of coordinates. I.e., no two nodes lie on the same point of the plane. Each node maps to integer coordinates. I.e., the nodes lie on a grid. For any node, call it A, all neighbors of A lie on a circle centered on A. I.e., all neighbors of any node have the same distance to that node. I couldn't draw a graph like this with max degree greater than 4, so I'm wondering whether 4 is indeed the max degree for this set of graphs. If not 4, perhaps it's 5 or 6? Edit: now I mechanically found the maximal

degree of a graph from this set to be 16, so the conjecture is disproved. It would still be nice if someone gave an answer that explains this intuitively.

Colinear and concurrency configuration in triangle involving arbitrary point

I found out this configuration while fooling around with Geogebra. I tried to solve it on my way back home from work but apparently it's not that easy. Is it a well-known theorem in elementary geometry? Let M is an arbitrary point inside the triangle ABC. AM, BM, CM intersects BC, CA, AB at D, E, F respectively. The line passing through A and parallel to BM intersects CM at H. Let K on AC such that $DK \parallel BM$. DH intersect AB at I. The parallel line to CM passed through A intersects BE at L. DL intersects AC at N, $O\in AB$ such that $DO \parallel CM$. Let P, Q be the intersections of HL and AB, AC respectively. EQ intersects PF at R; FN intersects IE at S. Let T be the midpoint of BC. Prove that: i- K, I, M; O, M, N are colinear. ii- AH, EF, KI; AL, EF, ON are concurrent. iii- A, R, S, T are colinear.

Prove conjecture about classification of circle pairings

I need help proving or disproving a conjecture related to circle pairings, which I'm trying to prove for my bachelor final project. I first present some needed terminology and context. A circle pairing of circles C and D is a Möbius transformation which maps D to C, maps the exterior of D to the interior of C, and maps the interior of D to the exterior of C. The circles which are paired are not unique. I'm trying to classify circle pairings based on the absolute value of the trace of the corresponding matrices (the group of Möbius transformations is isomorphic to the group of 2x2 invertible matrices modulo plusminus). I have already found the following results: Theorem 1: the most general way any circle pairing that pairs $C(x_1, r_1)$ and $D(x_2, r_2)$ can be written as is $$g(z)=x_1+r_1\cfrac{\bar{v}(z-x_2)+r_2 \bar{u}}{u(z-x_2)+r_2 v},$$ where $u,v\in \mathbb{C}:|u|^2-|v|^2=1$, where x_1, x_2 are the centers and r_1, r_2 are the radii of C and D. Lemma: the most general way any circle pairing f that pairs circles $C(x_1, r_1)$ and $D(x_2, r_2)$ such that $f(x_2)=\infty$ and $f(\infty)=x_1$, can be written as is $$x_1 +\cfrac{(H-x_2)(J-x_1)}{z-x_2},$$ where $H\in D$ and $J\in C$ (so $|H-x_2|=r_2$ and $|J-x_1|=r_1$). Theorem 2: for every circle pairing g given as in Theorem 1, which maps $\tilde{x}_2\mapsto \infty$ and $\infty \mapsto \tilde{x}_1$ there exist circles $C(\tilde{x}_1, r_1/|u|)$ and $D(\tilde{x}_2,r_2/|u|)$ such that g pairs C and D. In other words, every circle pairing as in Theorem 1, can be written in the form of the lemma above. Proof: We denote $\tilde{x}_1=x_1+r_1 \bar{v}/u$, $\tilde{x}_2=x_2-r_2 v/u$, $\tilde{r}_2=r_2/|u|=|H-\tilde{x}_2|$ and $\tilde{r}_1=r_1/|u|=|J-\tilde{x}_1|$, where $H=x_2+\tilde{r}_2$ and $J=\tilde{x}_1+\tilde{r}_1$. We get $$\begin{equation*} \begin{split} \tilde{x}_1 +\cfrac{(H-\tilde{x}_2)(J-\tilde{x}_1)}{z-\tilde{x}_2} & = x_1+r_1 \frac{\bar{v}}{u}+\cfrac{r_1 r_2 / u^2 }{(z-x_2)+r_2 v/u} \\ & = x_1+r_1(\frac{\bar{v}}{u}\frac{1/u [(z-x_2)+r_2 v/u]}{1/u [(z-x_2)+r_2 v/u]}+\cfrac{r_2/u^2}{(z-x_2)+r_2 v/u}) \\ & = x_1+r_1\cfrac{\bar{v}(z-x_2)+\bar{v} r_2 v/u+r_2/u}{u(z-x_2)+r_2 v } \\ & = x_1+r_1 \cfrac{\bar{v}(z-x_2)+r_2(\bar{v}v+1)/u}{u(z-x_2)+r_2 v} \\ & = x_1+r_1\cfrac{\bar{v}(z-x_2)+r_2 \bar{u}}{u(z-x_2)+r_2 v}. \\ \end{split} \end{equation*}$$ The absolute value of the trace of a circle pairing f as in Theorem 1 is $|Tr f|=\cfrac{|\tilde{x}_2-\tilde{x}_1|}{\sqrt{r_1 r_2 /|u|^2}}$, where $f(\tilde{x}_2)=\infty$ and $f(\infty)=\tilde{x}_1$ (so $\tilde{x}_1=x_1+r_1 \bar{v}/u$ and $\tilde{x}_2=x_2-r_2 v/u$). I have shown that if $|Tr f|>2$, then the radii of the circles C and D as given the existence of by Theorem 2 can be chosen such that C and D are disjoint (in short, if the $R_1=r_1/|u|$ and $ R_2=r_2/|u|$ are the radii of the paired circles then it can be shown that sR_2, R_1/s, where $s>0$, are also paired by f). If $|Tr f|=2$, then these circles can be chosen to touch (i.e. intersect in precisely one point), but never be disjoint. If $|Tr f|<2$, then these circles can only be chosen to overlap. The reason this is true is that the value for s for which these circles are the 'most disjoint' is such that the new radii $\hat{R_1}$ and $\hat{R_2}$ are such that $\hat{R_1}=\hat{R_2}=\sqrt{R_1 R_2}$. Circles are disjoint if $|x_1-x_2|>\text{sum of possible radii} \geq 2\sqrt{R_1 R_2}$, from which these conditions can be derived. We call a circle pairing f disjoint if $|Tr f|>2$, touching if $|Tr f|=2$ and overlapping if $|Tr f|<2$. Conjecture: if a circle pairing g is touching, then there exist no disjoint circles C and D such that g pairs these. If a circle pairing g is overlapping, then there exist no disjoint and no touching circles C and D such that g pairs these. In other words, the freedom of how disjoint the circles as given by Theorem 2 can be chosen, is such that it is the 'most disjoint' case of all possible circles that can be chosen to be paired. Theoretically, for some circle pairing g as given by Theorem 1, the points which are mapped from and to ∞ have to just be somewhere in the interiors of $C(x_1,r_1)$ and $D(x_2,r_2)$ which are paired by g. If they are the centers x_1 and x_2, then the classification of the conjecture is trivially true, but it is not clear what happens if they are not. Some things which may help to prove the conjecture which I have already considered but have not succeeded with: Note that the product of the radii of the circles as given by Theorem 2, namely $r_1 r_2 /|u|^2$, is smaller than that of the original radii r_1 and r_2 as given by Theorem 1, as $|u|>1$. Note that each of the fixed point(s) $f_{1,2}=1/2[\tilde{x}_1+\tilde{x}_2\pm \sqrt{4 r_1 r_2/u^2+(\tilde{x}_1-\tilde{x}_2)^2}]$, where again $\tilde{x}_1=x_1+r_1 \bar{v}/u$ and $\tilde{x}_2=x_2-r_2 v/u$, must either be in the interior of PRECISELY one of the circles that are paired, or be the intersection point(s) of these circles (this follows from the definition of circle pairings). Maybe the equation of g as given by Theorem 1 can be rewritten such that it equals itself, but where the values of x_1, x_2, r_1, r_2, u, and v are different. This should theoretically be possible for every pair of circles which g can pair. Maybe this could give insight into the freedom of possible circles which can be chosen to be paired, and why hypothetically the case where the centers are the points that map from and to ∞, would be the 'most disjoint' case. Maybe $|Tr f|$ can be related directly to the 'disjointness' of circles which can be chosen to be paired by g, similarly to how I did it already for the case for which the centers are the points which are mapped from and to ∞. In other words, maybe the logic itself I used to come up with the classification for the simple case, can be generalized to the general case. Hopefully anyone can find a proof or a counterexample.

Thanks in advance!

Is 3 the only prime that is both a Mersenne prime and a Fermat prime?

A Mersenne prime is a prime of the form 2^n-1. A Fermat prime is a prime of the form 2^n+1. Despite the two being superficially very similar, it is conjectured that there are infinitely many Mersenne primes but only finitely many Fermat primes. Here is my inquiry: QUESTION: Is 3 the only prime that is both a Mersenne prime and a Fermat prime? MY ATTEMPT The prime 3 is of the form $$3 = 2^2 - 1 = 2^{2^0} + 1$$ which shows that it is both a Mersenne prime and a Fermat prime. However, I am having trouble proving that it is the only such prime. Edited in response to an earlier closure of this question due to lack of context: (February 08, 2022 - 12:34 AM) My main motivation for having asked this question was to check whether an odd perfect number could be divisible by some prime that is both a Mersenne prime and a Fermat prime. As the excellent answers so show, 3 is the only such prime. However, (and this is the main caveat why I did not include this context earlier) it is currently unknown whether 3, or whether any prime below 105 for that matter, does divide an odd perfect number. To quote (or paraphrase, as I am currently unsure of the exact wording of) another mathematician's remark over at MathOverflow: "Such a result would be a major breakthrough in our understanding of odd perfect numbers."

A conjecture about non-nilpotent groups

A finite group, G, is nilpotent if its upper central series terminates (at $i \in \mathbb{N}$) with $Z^i(G)=G$, where $Z^i(G)$ is it's i-th center which can be described as $\{x \in G\mid \forall y \in G : [x,y]\in Z_{i-1}(G)\}$ where $[x,y]$ is the commutator of x and y in G (in other words, it is the set of elements that commute with one another up to an element of the $(i-1)$-th center). A finite group, G, is non-nilpotent if it is not nilpotent. In this case, we still have, by finiteness of G that the upper central series will terminate after finitely many steps, but now we have an $i \in \mathbb{N}$ at where $Z^i(G)=Z^{i+1}(G)$, and yet $Z^i(G)\neq G$, but rather a proper subgroup of G. In this case, since the upper centers are all characteristic and thus normal, we can consider the quotient group, $Q=G/Z^i(G)$. This group must be centerless, else we could take the pullback of $Z(Q)$ under the natural projection to obtain $Z^{i+1}(G)\supset Z^i(G)$ with equality not holding, contradicting our assumption that the upper central series stabilized at i. This gives a rather elegant characterization of non-nilpotent finite groups: A non-nilpotent finite group G can be viewed as an extension of a nilpotent normal subgroup, $U=Z^i(G)$ by a centerless quotient group, Q. In the most extreme case, the central series terminates immediately in the trivial group, and you obtain a centerless $G=Q$. This shows that the centerless groups are the primitive elements of the class of non-nilpotent finite groups with the rest being constructed from them by extensions of nilpotent groups by centerless groups. A (finite) group, G, is complete if it is centerless and isomorphic to its automorphism group $G\simeq\text{Aut}(G)$. Conjecture: Suppose we have a non-nilpotent finite group G, whose upper central series terminates at $i>0$, meaning that G is not centerless, and $Z^i(G)=Z^{i+1}(G)$. Let $U=Z^i(G)$, and suppose further that the centerless quotient $Q=G/U$ is complete, meaning $Q\simeq\text{Aut}(Q)$. Lastly, suppose that the upper central series for $\text{Aut}(G)$ terminates at some $i_1\geq i$, that is, the upper central series for $\text{Aut}(G)$ is at least as long as the upper central series for G. Note in particularly that $\text{Aut}(G)$ is non-nilpotent, and so has a centerless quotient Q_1. Then the claim is that the centerless quotients are isomorphic, $Q_1\simeq Q$. I came up with the conjecture based on computer searches in GAP looking at the automorphism series for various small finite groups as far as I could construct them in GAP (many eventually reach very large groups and run into issues with memory or the size of the computation). Looking at the upper central series for each term of the automorphism series and comparing how they changed as you step through the automorphism series lead me to propose that the above conjecture holds in general for finite groups. Naturally a counterexample will be enough to disprove the claim, but I didn't find any looking at over 50 different automorphism series, so it may not be easy to find if it exists. I'm not really sure how to approach trying to prove this either. I don't really know enough about the relationship between a group and its automorphism group to leverage the givens in this conjecture productively. Edit 1: This is a response to David A. Craven's answer: I took the liberty of constructing the proposed group in GAP for $n=7$. To do this, I needed to put all three of the G_i's into permutation groups so that the direct product operation in GAP would also return a permutation group, so that fast algorithms would be available for subsequent calculations. Specifically I used: G1:=SymmetricGroup(7); G2:=Group((1,2,3,4),(1,2)(3,4)); #This is D8 G3:=Group((1,2,3),(4,5,6),(7,8,9)); #This (Z_3)^3 #That G2 and G3 are as claimed can be checked by IdSmallGroup, is should return (8,3) for G2 and (27,5) for G3. #Now we can call DirectProduct and the result will be a permutation group G:=DirectProduct(G1,G2,G3); #Because this is a permutation group, computation of the upper central series is 'easy' for GAP, trying this without doing the above preparations lead to a computation that was taking minutes and still hadn't finished U:=UpperCentralSeriesOfGroup(G); From the above I obtained that G has upper central series of length 2. With $Z(G)\simeq (54,15)$, and $Z^2(G)\simeq (216,151)$ (Where (x,y) is the GAP library id for order x, id y.). GAP

StructureDescription for U[1] confirms that $Z^2(G)\simeq\mathbb{Z}_3^3\times D_8$. Next I constructed the quotient and confirmed it was the symmetric group (necessarily S_7 by an easy order argument). After a computation that took a few seconds I got the automorphism group, $A1$, but it was not in the form of a permutation group, so I used NiceMonomorphism and then NiceObject to obtain a permutation group isomorphic to the automorphism group. This allows for fast(er) algorithms to used for computing its upper central series, which I found to be of length 2 with $Z(A1)\simeq (8,5)$ and $Z^2(A1)\simeq (32,46)$ (again using GAP ids for the groups). The size of $A1$ is 905748480 which is twice that predicted in the answer (Which would be 452874240 if it had the structure given in the answer). I was able to get GAP to give me a structure description for $A1$, which was $\mathbb{Z}_2^2\times D_8\times S_7\times \text{PSL}(3,3)$. I suspect the comment that the proposed automorphism group is, in fact, a subgroup of index 2 in the full automorphism group is correct. The quotient $Q1$ is of order 28304640 (and so obviously not isomorphic to S_7), GAP gives a structure description of $S_7\times \text{PSL}(3,3)$ for this quotient. (So it is still a counter example for $i_1=i$ case).

Irreducible polynomials in $\mathbb Z[X]$ with no primes in the image.

It seems intuitive that if an irreducible polynomial $q\in\mathbb Z[X]$ has no primes in it's image, i.e. $n\in\mathbb Z\implies q(n)\notin \mathbb P$, then there is a non unit integer $m\in\mathbb Z$ such that $m|q(n)$ for all $n\in \mathbb Z$. But how to prove it? Example: $q(x)=4x^5-7x^4-4x^3-4x^2+7x+8$ is irreducible and $2|q(n)$ all n. I didn't have a single idea how to manage this, but I had a feeling that a theorem or conjecture was appropriate, but I had no key word, and thats the reason why I tagged reference-request

Does $\gcd$ of values of n-th degree primitive integer polynomial always divide $n!$?

Let's consider the following conjecture: Let $f(x)=a_0+a_1x+a_2x^2+\dots +a_nx^n$ be a primitive non-zero polynomial with integer coefficients and let $g=\gcd(\{f(k), k \in \mathbb{Z}\})$, then g divides $n!$. Or equivalently just: Let $0\not\equiv f(x)\in \mathbb{Z}[x]$, then $\gcd(f(k)) \mid c(f)\cdot (\deg f)!$. Here $c(f)$ is the content of a polynomial. Can we prove/disprove this? Edit: Found literature reference Today I found that g is called the fixed divisor of a polynomial and with this I was able to trace the same claim to the article Uber ganzwertige ganze funktionen by George Pólya from 1915. Unfortunately the article is in german so I am not sure how the proof goes (various articles mention this claim and cite this one without providing the proof themselves). Some thoughts I found this based on observation for small degrees. For $n=2$ and $\gcd(a_0,a_1,a_2)=1$ we can prove $g \mid 2$ (see below), and similarly for $n=3$ we can show $g \mid 6=3!$. I also wrote a simple script in Maple to verify over small degrees and coefficients range and haven't found a counterexample yet, so I wonder if this can be proven to hold in general. It can be useful that $\gcd(\{f(k), k \in \mathbb{Z}\})=\gcd(f(0),f(1),\dots,f(n))$ (or any consecutive $n+1$ integers for that matter). Currently I am thinking that Lagrange interpolation could be perhaps useful in generic case, I worked out that if we know f on consecutive integers $i=0,1,\dots,n$, then the Lagrange interpolation implies $$ f(x)=\sum_{i=0}^{n} (-1)^{n-i}\binom{x}{i}\binom{x-i-1}{n-i}f(i). $$ So I guess if we assume $\gcd(f(i))=d$ where $d \not\mid n!$, we should be able to use the above to reach contradiction with $f(x)$ having integer and coprime coefficients, but I wasn't able to. Proof for $n=2$ For $f(x)=a_0+a_1x+a_2x^2$ and $\gcd(a_0,a_1,a_2)=1$, we want to show $\gcd(f(-1),f(0),f(1)) \mid 2$. Now $f(-1)=a_0-a_1+a_2$, $f(0)=a_0$, $f(1)=a_0+a_1+a_2$ and so \begin{align} \gcd(f(-1),f(0),f(1)) &=\gcd(a_0-a_1+a_2,a_0+a_1+a_2,a_0)\\ &=\gcd(-a_1+a_2,a_1+a_2,a_0)\\ &=\gcd(2a_2,a_1+a_2,a_0)\\ \end{align} Now $g=\gcd(2a_2,a_1+a_2,a_0) \mid 2a_2$, but a_2 is coprime to g (otherwise we had a prime $p\mid a_2, p\mid a_1+a_2, p \mid a_0$ and so $p \mid \gcd(a_2,a_1,a_0)=1$, impossible). Hence $\gcd(2a_2,a_1+a_2,a_0) \mid 2$.

Primes of the form n^2+n+1

Let $f(n)=n^2+n+1$. While experimenting I found that Given $m,n\in\mathbb N, \: n>1$. If $f(2n)\in\mathbb P$ and $f((3m+1)n)\in\mathbb P$ then $3|n$. It has ben tested for $0\le m <1000$ and $1<n<1000$. I've tried to let $n=3k+i$ looking for polynomials of k for $i=1,2$ but it didn't work well. My hope is that someone can prove the conjecture.

Can two circles intersect each other at right angles, such that one circle passes through the center of the other circle?

More precisely, do there exist two intersecting circles such that the tangent lines at the intersection points make an angle of 90 degrees, and one of the circles passes through the center of the other? I think the answer is no, and that this can only be the case if the circle passing through the center of the other circle is actually a line. I'm not sure how to show this though. Can someone give a proof or a counterexample?

Real number version of the complex conjugate theorem?

Recently, I have encountered a question where a polynomial and one of its irrational roots $a+b\sqrt{c}$ where $a,b,c\in\mathbb{Q}, \sqrt{c}\in\mathbb{R}$ were given, and I was asked to find all roots. I immediately assumed that there existed a root $a-b\sqrt{c}$, and this was a correct assumption. Looking back, however, I am not entirely sure if this is true. I know that the complex conjugate theorem states that for any polynomial $p(x)$ with real coefficients, if the polynomial has a complex root $a+bi$ then it must also have a root $a-bi$. My question is if there is a real number version of such a theorem, which might go along the lines of something like: For a polynomial $p(x)=a_1x^n+a_2x^{n-1}+a_3x^{n-2}+\dots+a_{n-1}x+a_n$ with real coefficients a_n, if it has a root $a+b\sqrt{c}$ then $a-b\sqrt{c}$ must also be a root of $p(x)$. Or maybe instead of real coefficients it could be integer coefficients?

Generalizing the result $|a\times b|=|a||b||\sin \theta|$ to arbitrary dimensions.

The cross product can be generalized to arbitrary dimensions as done below or here. I'm trying to state and prove the general analogue (for arbitrary dimensions) of the equation $$|a\times b| = |a||b||\sin \theta |$$ where θ is the angle between a and b. Definition: let V be an inner product space of dimension n. The cross product of the vectors $v_1, \ldots ,v_{n-1}$ of V is defined as the unique vector v such that $$\det (u \ v_1 \ldots v_{n-1}) = u\cdot v$$ for every $u\in V$. It is denoted as $[v_1 \ldots v_{n-1}]$. Let $v_0, v_1, \ldots , v_{n-1}$ be vectors of an inner product space V (of dimension $n+1$). It is easy to show that the cross product $[v_0, v_1, \ldots ,v_{n-1}]$ is perpendicular to each v_i, and has a magnitude equal to the nth dimensional "area" of the parallelotope with edges $v_0, v_1, \ldots , v_{n-1}$. Let A be the $(n-1)$ dimensional area of the parallelotope with edges $v_1, \ldots , v_{n-1}$. That is, let $$A:=\sqrt{| \det G |}$$ where G is the Gram matrix of the vectors $v_1, \ldots, v_{n-1}$ (i.e. $G_{i,j}=v_i\cdot v_j$). Then the n-dimensional area of the parallelotope with edges $v_0, v_1, \ldots , v_{n-1}$ (namely $|[v_0, v_1, \ldots ,v_{n-1}]|$) should be $$A|v_0||\sin \theta |$$ where θ is the angle between v_0 and its projection v_0' onto the space $\langle v_1, \ldots , v_{n-1} \rangle$, namely $$v_0':=\sum_{i=1}^{n-1}\frac{v_0\cdot v_i}{|v_i|^2}v_i.$$ Is it true that $$|[v_0 \ v_1 \ldots v_{n-1}]| = A|v_0||\sin \theta| \ ?$$ If true, how could one prove it? If it isn't true, what am I getting wrong in my attempt to generalize the result stated in the introduction? My attempt at proving it: the expression $\sin \theta$ can be expanded by using the following definition of angle: $$\theta := \arccos \left(\frac{v_0\cdot v_0'}{|v_0||v_0'|}\right)$$ together with the fact that $\sin (\arccos (x))=\sqrt{1-x^2}$. Now A can be expanded in multiple ways (i.e. using Leibniz's definition of the determinant or the Laplace expansion). Finally, the LHS can be expanded by noting that $$[v_0 \ v_1 \ldots v_{n-1}] = \sum_{i=1}^{n+1}(-1)^{i+1}M_{1,i}e_i$$ where $\{ e_1, \ldots , e_{n+1}\}$ is a basis of V and $M_{1,i}$ is the determinant of the submatrix obtained by removing the ith row and the jth column of the matrix $$[1 \ v_0 \ v_1 \ldots v_{n-1}] .$$ I've been playing around with the resulting expression trying to force an equality, with no avail.

All solutions to $1/a+1/b=1/c$?

Conjecture: Given integers $a>b>c>1$ such that $\gcd(a,b,c)=1$. Then all the positive integer solutions to $$\frac{1}{a}+\frac{1}{b}=\frac{1}{c}$$ is given by: c any number and for each divisor $d<\sqrt{c}\:$ of $\,c\,$ with $\gcd(d,c/d)=1$ $$ \left\{ \begin{array}{l} a_d=c+d^2 \\ b_d=\frac{c}{d}\cdot(\frac{c}{d}+d)=c\cdot(c+d^2)/d^2 \end{array} \right. $$ It is easy to show that a_d,b_d,c all are solutions, but how to prove they are the only solutions?

On the inequality $I(q^k)+I(n^2) \leq \frac{3q^{2k} + 2q^k + 1}{q^k (q^k + 1)}$ where $q^k n^2$ is an odd perfect number

(Note: This post is an offshoot of this earlier MSE question.) Let $N = q^k n^2$ be an odd perfect number with special prime q satisfying $q \equiv k \equiv 1 \pmod 4$ and $\gcd(q,n)=1$. Define the abundancy index $$I(x)=\frac{\sigma(x)}{x}$$ where $\sigma(x)$ is the classical sum of divisors of x. Since q is prime, we have the bounds $$1 < \frac{q+1}{q} \leq I(q^k) < \frac{q}{q-1} \leq \frac{5}{4},$$ which implies, since N is perfect, that $$\frac{8}{5} \leq \frac{2(q-1)}{q} < I(n^2) = \frac{2}{I(q^k)} \leq \frac{2q}{q+1} < 2.$$ By considering the nonnegative product $$\bigg(I(q^k) - \frac{q+1}{q}\bigg)\bigg(I(n^2) - \frac{q+1}{q}\bigg) \geq 0,$$ then after some routine algebraic manipulations, we arrive at the upper bound $$I(q^k) + I(n^2) \leq 3 - \Bigg(\frac{q-1}{q(q+1)}\Bigg) = \frac{3q^2 + 2q + 1}{q(q + 1)}.$$ Here, I shall derive the following slightly different bound: If $q^k n^2$ is an odd perfect number with special prime q, then $$I(q^k) + I(n^2) \leq \frac{3q^{2k} + 2q^k + 1}{q^k (q^k + 1)}.$$

PROOF: Suppose that $q^k n^2$ is an odd perfect number with special prime q. Then we have $$\sigma(q^k) \geq q^k + 1$$ so that $$\frac{1}{4} \geq \frac{1}{q-1} > I(q^k) - 1 \geq \frac{1}{q^k}$$ and $$1 > \frac{q-1}{q+1} \geq I(n^2) - 1 > \frac{q-2}{q} \geq \frac{3}{5}$$ so that we obtain $$\Bigg(\bigg(I(q^k) - 1\bigg) - \frac{1}{q^k}\Bigg)\Bigg(\bigg(I(n^2) - 1\bigg) - \frac{1}{q^k}\Bigg)$$ is nonnegative. Thus, we have $$\Bigg(\bigg(I(q^k) - 1\bigg) - \frac{1}{q^k}\Bigg)\Bigg(\bigg(I(n^2) - 1\bigg) - \frac{1}{q^k}\Bigg) \geq 0$$ which is equivalent to $$\bigg(I(q^k) - 1\bigg)\bigg(I(n^2) - 1\bigg) + \frac{1}{q^{2k}} \geq \frac{1}{q^k}\Bigg(I(q^k) + I(n^2) - 2\Bigg)$$ $$\Bigg(3 - \bigg(I(q^k) + I(n^2)\bigg)\Bigg) + \frac{1}{q^{2k}} \geq \frac{1}{q^k}\Bigg(I(q^k) + I(n^2) - 3\Bigg) + \frac{1}{q^k}$$ $$\Bigg(\frac{q^k + 1}{q^k}\Bigg)\Bigg(3 - \bigg(I(q^k) + I(n^2)\bigg)\Bigg) = \Bigg(1 + \frac{1}{q^k}\Bigg)\Bigg(3 - \bigg(I(q^k) + I(n^2)\bigg)\Bigg) \geq \frac{1}{q^k} - \frac{1}{q^{2k}} = \frac{q^k - 1}{q^{2k}}$$ $$3 - \bigg(I(q^k) + I(n^2)\bigg) \geq \frac{q^k - 1}{q^k (q^k + 1)}.$$ Hence, we finally get $$I(q^k) + I(n^2) \leq 3 - \Bigg(\frac{q^k - 1}{q^k (q^k + 1)}\Bigg) = \frac{3q^{2k} + 2q^k + 1}{q^k (q^k + 1)}.$$ QED. Notice the striking similarity between the upper bound $$I(q^k) + I(n^2) \leq 3 - \Bigg(\frac{q-1}{q(q+1)}\Bigg) = \frac{3q^2 + 2q + 1}{q(q + 1)},$$ and the upper bound $$I(q^k) + I(n^2) \leq 3 - \Bigg(\frac{q^k - 1}{q^k (q^k + 1)}\Bigg) = \frac{3q^{2k} + 2q^k + 1}{q^k (q^k + 1)}.$$ Here are my: QUESTIONS: (1) Does this argument imply that $k=1$? (i.e. in the sense that k is taken to be a placeholder for 1?) (2) Similar to the train of thought in this post, can you think of a way to show that $$I(q^k) + I(n^2) > 3 - \Bigg(\frac{q^k - 2}{q^k (q^k - 1)}\Bigg) = \frac{3q^{2k} - 4q^k + 2}{q^k (q^k - 1)}?$$ (3) If it is not possible to prove the inequality in (2), can you explain why?

Primes being a square sum of an odd number and a less number

For natural numbers a,b, let a be odd and let $f(a)$ be the number of $\,b<a\,$ such that a^2+b^2 is prime. In the diagram f is blue, the function $g(n)=\frac{n}{\ln n}$ is red and $h(n)=\frac{1}{\pi}\cdot\frac{n}{\ln n}$ is green. Since the blue curve is nearly limited by the red and the green curves it seems reasonable to make the conjecture: There are real numbers A and B such that $A\cdot\frac{n} {\ln n}<f(n)<B\cdot\frac{n}{\ln n}$, where n is odd. What would be the intuition behind this?

If $\gcd(n^2, \sigma(n^2)) = q\sigma(n^2) - 2(q - 1) n^2$, does it follow that $q n^2$ is perfect?

Let q be an (odd) prime, and let $\gcd(q,n)=1$. Denote the classical sum of divisors of the positive integer x by $\sigma(x)=\sigma_1(x)$. A number N is said to be perfect if $\sigma(N)=2N$. Here is my question: If $\gcd(n^2, \sigma(n^2)) = q\sigma(n^2) - 2(q - 1) n^2$, does it follow that $q n^2$ is perfect? CONTEXT It is known that if $p^k m^2$ is perfect, where p is an odd prime satisfying $\gcd(p,m)=1$, then we obtain $$i(p):=\dfrac{\sigma(m^2)}{p^k}=\dfrac{2m^2}{\sigma(p^k)}=\dfrac{D(m^2)}{s(p^k)}, \tag{*}$$ where $D(x)=2x-\sigma(x)$ is the deficiency of x and $s(x)=\sigma(x)-x$ is the aliquot sum of x. (Note that $i(p)$ is odd.) We then obtain $$\sigma(m^2) = p^k {i(p)}$$ and $$m^2 = \dfrac{\sigma(p^k)}{2}\cdot{i(p)},$$ so that $$\gcd(m^2, \sigma(m^2)) = i(p)\cdot\gcd\Bigg(p^k, \dfrac{\sigma(p^k)}{2}\Bigg) = i(p).$$ Additionally, we can also rewrite Equation (*) as $$i(p) = \dfrac{\sigma(m^2)}{p^k} = \dfrac{D(m^2)}{s(p^k)} = \dfrac{(p-1)D(m^2)}{p^k - 1} = \dfrac{\sigma(m^2) - (p-1)D(m^2)}{p^k - (p^k - 1)}$$ $$= p\sigma(m^2) - 2(p-1)m^2.$$ Specializing to $k=1$, we obtain the implication $$qn^2 \text{ is perfect with } \gcd(q,n)=1 \implies \gcd(n^2, \sigma(n^2))=q\sigma(n^2) - 2(q-1)n^2.$$ SANITY CHECK Let qn^2 be an even perfect number. Then $q = 2^t - 1$ and $n^2 = 2^{t-1}$, for some prime number t. We compute $$\gcd(n^2, \sigma(n^2)) = \gcd(2^{t-1}, 2^t - 1) = 1$$ and $$q\sigma(n^2) - 2(q - 1)n^2 = (2^t - 1)(2^t - 1) - 2(2^t - 2){2^{t-1}} = 2^{2t} - 2^{t+1} + 1 - 2^{2t} + 2^{t+1} = 1,$$ whence we have equality between $\gcd(n^2, \sigma(n^2))$ and $q\sigma(n^2) - 2(q - 1)n^2$. (Note that these computations also "work" for the even perfect number 6, even though it is squarefree.) PROBLEM This takes care of one direction. Can you come up with a proof for the other direction? Alas, this is where I get stuck.

Is the following infinite product of fractions of linear factors equal to an exponential function or not?

Is the following infinite product: $$ \prod_{\substack{(a,b) \in \mathbb{Z}^2 \\ a > b}} \frac{x+b}{x+a} $$ defined? If so, does it simplify to an exponential function of x? The subscript is over all integer pairs a and b such that $a>b $ Motivation/suggestions: When plotting a graph of a finite truncation of the product : it resembles a negative exponential function. However such an approximation appears to not be accurate for small values of x (where it has vertical asymptotes). Can it be transformed in such a way that it becomes an exponential function, by modifying each term individually so that the whole function is finite and the asymptotes lie at infinite distance in the limit? Or can we show that the derivative of this infinite product with respect to x is a constant factor of itself or not, thus proving that it is an exponential? I believe it should be exponential because it was obtained by raising e to the power a modified version of an integral of a constant function.

How much Base Proof is required?

If I were looking to use the Theory of Strong Induction, to prove the statement that: The Set of All Even Numbers is equal to the Set of All Odd Numbers multiplied by 2^n, where $n \geq 1$ $$ \mathbb{E} = \mathbb{O} \cdot \{2^n \mid n \geq 1 \} $$ How much Base Proof would be required to show or infer that it is true? $2 = 1 \cdot 2^1$ $4 = 1 \cdot 2^2$ $6 =

3 \cdot 2^1$ $8 = 1 \cdot 2^4$ $10 = 5 \cdot 2^1 \dots$ I get that for Strong Induction you have to show all the base proofs up to a certain point. But in this case, what would that minimum requirement be? Is there a minimum amount required, or is this what makes a Conjecture? Because the base proof requires an infinite number of base proofs, to prove the statement and relies more on a formula for its proof over Strong Induction?

What is the distribution of ax^2+bx+c as $\{a,b,c,x\}$ vary over $\mathbb Z$? (re: quadratic primes)

I realize this may be one of those questions where it's ill-posed and can't be answered without further constraints. But if not, what's the distribution like? In particular, is every integer equally often represented? On the one hand, that appears likely based on the observation that regardless of what effect $\{a,b,x\}$ might have, c can serve to exactly map one $\{a,b,x\}$ tuple to every integer. On the other hand, this feels suspiciously like one of those things that turns out to depend on how exactly you enumerate a,b,c,x as you walk towards infinity. I am also suspicious because of how I arrived at this question, via basic thoughts on the infinitude of quadratic primes. I reasoned as follows: Suppose there are only finitely many quadratic primes, and let $f(x)=ax^2+bx+c$ be some function that returns primes for finitely many values of x. Let m,n be the largest and smallest x such that $f(x)$ is prime, and let k be any integer outside of the interval $[n,m]$. Then $f'(x)=f(x+k)=ax^2+bx+c+ak^2+bk+2axk$ will be a quadratic function which is irreducible but always composite. Moreover, since there are infinitely many k values yielding never-prime quadratics compared to finitely many k that are sometimes prime, and the same would apply to any quadratic function used, it seems to follow that almost all quadratic functions must yield no primes. And that brings us full circle, since if ax^2+bx+c could be said to be "evenly distributed" in some meaningful way, and if my logic above holds, we'd have a contradiction proving infinitude of quadratic primes. Since we don't, quadratics must not be evenly distributed, and/or my logic above is flawed. If someone could point out where I've gone astray, I'll consider my question answered. Edit: Okay, let's do the naive thing and increase some $i\to\infty$ and consider a,b,c,x in range $[-i,i]$.

For any composition sequence s of maps $h(X)=X/2, \ f(X)=(3X + 1)/2$, there exists an integer X such that its Collatz sequence contains s

Let $h(X) = X/2$, and $f(X) = (3X + 1)/2$. Then clearly every iteration $g^i(X), X \in \Bbb{Z}$ the Collatz mapping $$g(X) = \begin{cases} X/2, \ X=0\pmod 2\\ \dfrac{3X + 1}{2}, \ X = 1\pmod 2 \end{cases}$$ can be modelled by compositions of f, h. For example, $g^7(3) = 1 = hhhff(3)$ where $g(X) = f(X)$ for odd numbers and $g(X) = h(X)$ for even numbers. Under iterations of g, each number $X \in \Bbb{Z}$ induces a unique composition of f and h functions. This should be clear because a number is either even or odd but not both, so at each stage in an iteration there is one and only one function (f or h) to apply. Conjecture. For any sequence $s \in \{f,h\}^*$ (Kleene closure under $\circ$) there exists an integer X such that $g^i(X) = s(X)$ for some $i \geq 0$. Can we prove this or is it just as difficult as Collatz? Clearly we have that it's true for the sublanguage $\{h\}^*$ since we can take $g^n(2^n) = h^n(X)$ for all $n \geq 0$. Clearly we have that it's true for the sublanguage $\{h\}^*$ since we can take $g^n(2^n) = h^n(X)$ for all $n \geq 0$. It's also true for $f\{h\}^*$ since $X = 2^n O$ works, where O is an odd number. And it's true for $\{h\}^* f$ since $3O + 1 = 2^ny$ has a solution if and only if $30 + 1 = 0 \pmod 2^n \iff O = -3^{-1} \pmod 2^n$. So in fact we've proven an infinitude of solutions namely: $-3^{-1} + 2^n\Bbb{Z}$ for any $h^n f \in \{h\}^* f$. Let these two proofs comprise a base case for induction on the number of f's appearing in s.

Why does one counterexample disprove a conjecture?

Can't a conjecture be correct about most solutions except maybe a family of solutions? For example, a few centuries ago it was widely believed that $2^{2^n}+1$ is a prime number for any n . For $n=0$ we get 3 , for $n=1$ we get 5 , for $n=2$ we get 17 , for $n=3$ we get 257 , but for $n=4$ it was too difficult to find if this was a prime, until Euler was able to find a factor of it. It seems like this conjecture stopped after that. But what if this conjecture isn't true only when n satisfies a certain equation, or when n is a power of 2 $\ge$ 4 , or something like that? Did anybody bother to check? I am not asking about this conjecture specifically, but as to why we consider one counterexample as proof that a conjecture is totally wrong. P.S. Andre Nicolas pointed out that Euler found a factor when $n=5$, not 4 .

What can we say about the colourings of some subset of vertices of a graph

I will clarify the question by defining some straightforward concepts. Let G = (V, E) be a simple graph with chromatic number k. We call a subset $V'\subset V$ fully chromatic if every proper k-colouring of G uses also k distinct colors on V'. We say such a fully chromatic set is minimal, if every subset of V' is not fully chromatic. Now I conjecture that for every G=(V, E) and every minimally chromatic set $V'\subset V$, there exists some graph $G^* = (V^*, E^*) $ that has the same proper k-colourings on V^* as all proper k-colourings of G restricted to V'. Furtermore, I conjecture that G has G^* as a minor

Proof for strict inequality $\pi(ab) > \pi(a)\pi(b)$?

I asked about the very similar $\pi(ab)\geq \pi(a)\pi(b)$ a while ago, and this is indeed a proven result for $a,b\geq \sqrt{53}$. Empirically, the stricter $\pi(ab)>\pi(a)\pi(b)$ looks true so long as either a or b is ≥ 23. It also seems to pretty immediately fall out of the PNT, a la $$\pi(ab)\sim\frac{ab}{\log(ab)}>\frac{ab}{\log(a)\log(b)}\sim \pi(a)\pi(b)$$ given sufficiently large a,b. If someone can point me to a paper, give pointers/work out on how this proof could be done, or if applicable, explain why this is probably not provable, I'll consider this answered. If you can verify my proof below or give some solid feedback, that would work too. Okay, I have a first attempt. For $x\geq 17$, Wikipedia gives the bounds $$\frac x {\log x} < \pi(x) \tag{1}$$ $$\pi(x) < 1.25506 \frac x {\log x}. \tag{2}$$ From applying (2) twice, we have $$\pi(a)\pi(b) < 1.25506^2 \cdot \frac{ab}{\log(a)\log(b)}.\tag{3}$$ From (1), we get $$\frac{ab}{\log(ab)} < \pi(ab).\tag{4}$$ It only remains to connect them: $$1.25506^2 \cdot \frac{ab}{\log(a)\log(b)} < \frac{ab}{\log(ab)}.\tag{5}$$ From trial and error, letting $a,b \geq 24$ seems sufficient to satisfy (5). We put the pieces together and get the final inequality chain $$\pi(a)\pi(b) < 1.25506^2 \cdot \frac{ab}{\log(a)\log(b)} <\frac{ab}{\log(ab)} < \pi(ab). \tag{6}$$ This gives $\pi(a)\pi(b)<\pi(ab)$ for $a,b\geq 24$. Have I gone awry somewhere or does this work?

Asymmetric graphs where all adjacent vertices have different degree

I conjecture the following : If G is a graph so that every pair of adjacent vertices have different degree, then G is not asymmetric graph. I will remind that a graph is a asymmetric if there are no automorphisms, except for the trivial automorphisms. It is possible that this statement is incorrect. Can someone find a counterexample? And a similar conjecture: If G is a 2-connected chordal graph, then it contains a triangle where at least two vertices are of the same degree.

I conjecture that the circumference of a graph is larger than its average degree

Let $G = (V,E)$ be a simple loop-less graph. The circumference refers to the length of the largest cycle of G. The average degree is $avg(G) = |E|*2 / |V|$. I conjecture that if the avg(G) > 2, then $circum(G) > avg(G)$. I can prove that the circumference is larger than the minimum degree of G. This can be quite easily seen by looking at the maximum path of G. The neighbors of the endpoints must then all lie within the path. Connecting one endpoint with it's neighbor that lies the furthest on the path would then result in a cycle of at least the degree of the endpoint + 1. Any idea how to prove my stronger claim?, or a counter-example?

Is there anything known about the tree width of the direct sum of two graphs?

So, if you have two graphs (both with a designated edge), you could take the direct sum of those two graphs, where you glue those two graphs to each other along the designated edge. I think different literature use different definitions. Anyways, see the picture below as an example of gluing two cycles to each other of length 6 along some edge. I was wondering if there is anything known about what happens to the tree width of the new graph, given the tree widths of the original two graphs? Is there some literature about it. I thought perhaps that $tw(G \oplus H) = \max({tw(G), tw(H)})$, where $\oplus$ denotes the operation I described above, and tw being the tree width. I'm not even sure if this is true, and if it'd be true, where I could read more about this, or whether there are known proofs I could refer to. If not, maybe something is known about tree widths of graphs under different kind of operations. If something is unclear about my question, let me know. Thank you!

I have a conjecture regarding vertex coloring

Let $G = (V, E)$ be a graph with chromatic number $n+1$, and let there be some vertex $v* \in V$, so that deleting this vertex results in a graph $G/{v*}$ that has chromatic number n. Now, assign to $G/{v*}$ any proper n-coloring, then color $v*$ in the $(n+1)-th$ color. Rainbow Conjecture: Choose at least 2 (and at most n) distinct colors from the first n colors, and order these in any way. I conjecture that there exists a cycle in G that contains $v*$, and so that the colors we come across when we traverse this cycle starting from $v*$, are precisely (one or multiple) repetitions of the chosen pattern. So cycles are for example colored like: $v*$ - blue - green - red - ($v*$) , or $v*$- blue- red - blue - red - ($v*$). And these cycles exist for all proper n-colorings of $G/{v*}$ and any combination and order of the n colors. The reason why I think this might be true is because if there would be an ordering that doesn't have a matching path that starts at $v*$, for example: if we can't go from $v*$ to a red vertex and then a green vertex, then all red neighbors of $v*$ don't have green neighbors, so we could change them all to green, but then we could change $v*$ to red, which would result in a n-coloring of G. But this doesn't really explain why the path must also come back to $v*$. My conjecture seems quite optimistic, however, I haven't been able to find a counter example. What do you guys think? Thanks for your time, and I'd love to see if someone can find a counterexample (or a proof even better). I guess counterexamples would have generally high girth or low clique.

Why does e/π (or $1/2$) arise in this limit?

(Related to this prior post.) Let $f(n)$ for $n\in\mathbb N$ be a function that increases the prime index of each prime factor of n (with multiplicity) by 1. e.g. $f(20)=f(2^2\cdot 5)=f(p_1^2\cdot p_3)=p_{2}^2\cdot p_{4}=3^2\cdot 7=63$. Consider $\frac{n}{f(n)}$ as $n\to\infty$. The mean of these terms has a clear limit: $$\lim_{n\to\infty} \left(\frac{1}{n}\sum_{i=1}^n \frac{i}{f(i)}\right)=\frac{1}{2}.$$ But more interesting is that if you let a be a count of how many terms through n have $\frac{i}{f(i)}>\frac{1}{2}$, and therefore $n-a$ be the count of terms with $\frac{i}{f(i)}<\frac{1}{2}$, then it appears that $$\lim_{n\to\infty} \frac{a}{n-a}=\frac{e}{\pi}.$$ This is a strictly empirical result, but it seems to hold within a margin of error of around $\frac{1}{\sqrt{a}}$. So far, I've checked this for $n\leq 10^7$, and while the results aren't strong enough to rule out coincidence yet, it seems too suggestive to ignore. Does anyone know why this might arise? And if it's correct, might it imply that $\frac{e}{\pi}$ is irrational? It seems to me that $\frac{a}{n-a}$ can't be rational in the limit since it will never cease to fluctuate in finer pseudorandom detail based on the distribution of the primes, but perhaps the limit negates that somehow. If anyone can explain why the limit $\frac{e}{\pi}$ would appear here (or can show that I'm mistaken), I'll consider this answered. Update The more I look, the less convinced I am that I had this right; I still believe there's a limit, but not e/π, as it seems to run about 0.002 higher pretty consistently. As for the $1/2$ limit, I'm quite sure that's solid. Empirical data leaves essentially no doubt, and it's very much in line with the behavior of f, which has properties like for any n, you'll get $f(k)> n$ for exactly half of the naturals $k\in [1,n]$. (See this post for more.) That said, I don't know how to prove the $1/2$ limit, so I'd accept that as an answer here as well if someone can demonstrate it. Basic notes on $\frac{i}{f(i)} > \frac{1}{2}$ properties Let $S_n = \{1 \leq s \leq n : f(s) > 2s\}$. (Note $f(s) > 2s$ is equivalent to $\frac{s}{f(s)} < \frac{1}{2}$, but cleaner looking.) Regardless of choice of n, $|S_n|$ will be slightly larger than $n/2$. Example $S_{128}=\{4, 6, 8, 9, 10, 12, 14, 15, 16, 18, 20, 21, 24, 27, 28, 30,\\ 32, 35, 36, 39, 40, 42, 44, 45, 48, 49, 50, 52, 54, 56, 57, 60, 63, 64, 66,\\ 68, 69, 70, 72, 75, 76, 78, 80, 81, 84, 88, 90, 91, 92, 96, 98, 99, 100,\\ 102, 104, 105, 108, 110, 112, 114, 116, 117, 120, 124, 125, 126, 128\}.$ $|S_{128}|=67$. This set can be substantially compressed by eliminating multiples, leaving $\{4, 6, 9, 10, 14, 15, 21, 35, 39, 49, 57, 69, 91, 125\}$. Any integer divisible by any of these values will also have the property $f(i) > 2i$. It is clear with a little inspection that there will be infinitely many of these values as n is made arbitrarily large. Various patterns abound, e.g. $5^2 \cdot p_i$ will be one of these minimal elements for all $i \geq 3$. The overall distribution appears complex, similar to the primes themselves in many ways. All integers in these S sets are necessarily composite, as having a prime would violate Bertrand's postulate. On the whole, elements in these sets are "especially" composite, with larger factor counts and smaller factors. Contrast this to the complementary set R_n comprising those $r\leq n$ such that $f(r) < 2r$: Example $R_{128}=\{1, 2, 3, 5, 7, 11, 13, 17, 19, 22, 23, 25, 26, 29, 31, 33,\\ 34, 37, 38, 41, 43, 46, 47, 51, 53, 55, 58, 59, 61, 62, 65, 67, 71, 73,\\ 74, 77, 79, 82, 83, 85, 86, 87, 89, 93, 94, 95, 97, 101, 103, 106,\\ 107, 109, 111, 113, 115, 118, 119, 121, 122, 123, 127\}.$ $|R_{128}|=61.$ R_n necessarily contains all the primes $\leq n$ as well as most $2p$, p^2, and other semiprime forms; in general, it is populated by high-prime-index low-factor-count integers, as expected from the complement to S_n.

fundamental solution of Pell’s equation under special conditions

I make the following conjecture from an answer. conjecture Suppose N could be expressed as $$ N= p^2\pm q,\ \ \ (p,q \in \mathbb{N},\ 1 \lt q \lt p,\ q\mid 2p) $$ In this case, the fundamental solution of $x^2-Ny^2=1$ is obtained by the following expression. (double sign in same order) $$ x_0=\frac{2p^2}{q} \pm 1,\ \ y_0=\frac{2p}{q} $$ (x_0,y_0) is one of the solutions of $x^2-Ny^2=1$ because it can be calculated as follows. \begin{eqnarray*} x_0^2-Ny_0^2&=& \left(\frac{2p^2}{q} \pm 1\right)^2-(p^2\pm q)\cdot \left(\frac{2p}{q}\right)^2\\ &=& \frac{4p^4}{q^2} \pm \frac{4p^2}{q} +1 -\frac{4p^4}{q^2} \mp\frac{4p^2}{q}\\ &=& 1 \end{eqnarray*} But, I don't know how to prove that it is the fundamental solution. concrete example Let N be 75. The expression using the square number of the nearest neighbors is $$ 75 = 9^2-6 $$ $p=9,\ q=6$ satisfy $1 \lt q \lt p$ and $\ q\mid 2p$. Therefore, \begin{eqnarray*} x_0&=&\frac{2p^2}{q} - 1,\ \ \ y_0&=&\frac{2p}{q} \\ &=& \frac{2\cdot 9^2}{6} -1 &=& \frac{2\cdot 9}{6} \\ &=& 26 &=& 3 \end{eqnarray*} $(x_0, y_0) = (26, 3)$ is the fundamental solution of $x^2-75y^2=1$.

Conjecture about areas of circular segment and polygon with equal perimeter sharing a side

I was playing around with shapes and have formed a conjecture. Length of the red circular arc $=$ total length of the n green line segments Conjecture: $$\sup{\left(\frac{\text{Area}_1}{\text{Area}_2}\right)}=\sqrt{1-\frac{1}{n^2}}$$ Is my conjecture true, and if so, is it a known thing? I have proven the case with $n=2$ algebraically, and (I think) I have verified the cases with $n=3$ and $n=4$, using desmos. The case with $n=2$: The ratio of the areas is maximized when the two green segments are the same length (this can be seen by considering the ellipse whose focal points are the ends of the black line, passing through the point where the two green segments meet). I let the central angle of the arc be 2θ, and got $$\frac{\text{Area}_1}{\text{Area}_2}=\frac{2(\sin{\theta})\sqrt{\theta^2-\sin^2{\theta}}}{2\theta-\sin{2\theta}}$$ Basic calculus shows that this function is decreasing in $0<\theta<\pi$, and the limit as $\theta\to0^+$ is indeed $\frac{\sqrt{3}}{2}$. Applying a similar method to larger n seems quite daunting. (My background: high school math teacher.)

A function asymptotical equivalent with the prime counting function?

Let p_n be the n-th prime number and $Q_a(N)$ be the number of primes of the form p_n^2+a where $1\leq n\leq N$ and a is positive and even. For some a like $26,56$ it seems that no solutions to $p_n^2+a\in\mathbb P$ exist, for some a like $2,8$ there seems to be a unique solution and for some a like $4,12$ there seems to be an unlimited number of solutions. The diagrams below is of $Q_4(N)$ (blue) and the function $\frac{N}{\ln N}$ (red). My question, is it possible to prove that $Q_4(N)\sim\frac{N}{\ln N}$?

Conjecture that $\sum\limits_{n=1}^{\infty}\big(\frac 1{q^{p_n}-1}-\sum\limits_{k=1}^{n-1}\frac 1{q^{p_n p_{n-k}}-1}\big)=\frac 1{q(q-1)}$

I have had this conjecture for a while: Let $q\in\mathbb R\setminus [-1,1]$ and let p_n be the n^th prime. Then: $$\sum_{n=1}^{\infty}\bigg(\frac 1{q^{p_n}-1}-\sum_{k=1}^{n-1}\frac 1{q^{p_n p_{n-k}}-1}\bigg)=\frac 1{q(q-1)}$$ The sum looks like this when we expand it out: $$\frac 1{q^2-1}+\bigg(\frac 1{q^3-1}-\frac 1{q^{3\times 2}-1}\bigg)+\bigg(\frac 1{q^5-1}-\frac 1{q^{5\times 3}-1}-\frac 1{q^{5\times 2}-1}\bigg)+\cdots=\frac 1{q(q-1)}$$ I don't know how to show something like this. I can pull out a factor of $1/(q-1)$ but I don't think that will help. Is this even true? I just had it written down in my notebook. (Sorry for not having any good proof attempts of my own.)

Extending a simple 1-dimensional observation to 2-dimensions.

Consider the following (easy to prove) statemnt. Statement 1. There is an absolute constant c_1 such that whenever $n\geq 1$ and $x_1, \ldots, x_n$ are real numbers such that $|x_i| \leq 1$ for all i and $\sum_{i=1}^n x_i = 0$, one can find a permutation σ of $\{1, \ldots, n\}$ such that each of the numbers in the sequence $$ x_{\sigma(1)},\ x_{\sigma(1)} + x_{\sigma(2)},\ x_{\sigma(1)} + x_{\sigma(2)} + x_{\sigma(3)}, \ldots, x_{\sigma(1)} + \cdots + x_{\sigma(n)} $$ has magnitude at most c_1. In fact, one can easily show that $c_1 = 1$ works. Pick x_1 and set $\sigma(1) = 1$. If $x_1>0$, find a negative x_i and set $\sigma(2) = i$ and continue greedily. The following is the two dimensional version of the above statement, but it is quite unclear to me if it is true of not. Statement 2. There is an absolute constant c_2 such that whenever $n\geq 1$ and $x_1, \ldots, x_n$ and $y_1, \ldots, y_n$ are two sequences of real numbers such that $|x_i|, |y_i|\leq 1$ for all i, and $\sum_{i=1}^n x_i = \sum_{i=1}^n y_i = 0$, one can find a permutation σ of $\{1, \ldots, n\}$ such that for each $1\leq k\leq n$, the magnitude of both of $$ x_{\sigma(1)} + x_{\sigma(2)} + x_{\sigma(3)} + \cdots + x_{\sigma(k)}, \quad y_{\sigma(1)} + y_{\sigma(2)} + y_{\sigma(3)} + \cdots + y_{\sigma(k)} $$ is at most c_2.

Strong induction on the maximum size of a set

I'm currently working on an advancement of the Union-closed sets conjcture, and I have a whole cascading series of implications that follow from one claim, and try as I may, I have not been able to prove this claim (I will provide intuition for why it could be true later on) Given a union closed family, F, on an m-universe, that is, F a collection of subsets of the set: $$ U:= \{1, 2,...,m\} $$ with the property that the union of any two sets in F is also in F Then define the k^{th} layer of of F as $L_k(F) = \{X \in F: |X| = k \}$ The claim that I am trying to prove is that if every element of U appears in exactly $$ 2^{m-1} - \sum_{i=1}^n \binom{m-1}{i-1}$$ Sets in F, for some $n<m$ then the maximum size of F is $$2^{m} - \sum_{i=1}^n \binom{m}{i}$$ Those quantities arise precisely from removing the first n layers of the powerset of U, $\mathcal{P}(U)$ and so what the claim is saying is that this is the least amount of sets you can hope to remove so that each element appears exactly that amount of times. For the powerset itself, i.e when $n=0$ this is indeed true, and every element appears 2^m times, and for $n=1$ it seems that not only is it true but this is in fact the only removal which results in every element appearing exactly $2^m -1$ times I tried attacking this with a strong induction, assuming that for every n up to k, this was the maximum size of F, and then showing that it must also be the maximum size for $n=k+1$ the intuition being that if you were to remove some sets from some of the "higher" layers of $\mathcal{P}(U)$, you would necessarily need to remove some sets from all the layers "below" it, to preserve the union-closed property, and indeed, if you remove only one set X_k from $L_k(\mathcal{P}(U))$ then you have to remove at least $k-1$ sets from $L_{k-1}(\mathcal{P}(U))$ to preserve the union-closed property, and the single removal of X_k can be substituted for an equivalent removal of some X_{k-1} from the layer below it, along with the previously removed $k-1 $ sets from this layer (equivalent in terms of the minimum decrease in appearance of all the elements in X_k) and so removing only from the layer $L_{k-1}(\mathcal{P}(U))$ is at least as effective as removing from both layers. This leads one to think that all the ingredients for an inductive step are present, but I haven't been able to complete it, since it gets considerably more complicated to "keep track of things" once you start removing more than simply one set from an otherwise full layer. Any help would be appreciated, if this were to be proben it would be a significant step forward for the conjecture (sorry,thought it too space consuming to include the description of the original conjecture too), accordingly, any complete answers will get at least an acknowledgment.

Three hyperbolas related to a triangle concur at two points

I found this interesting fact (which I believe is non-trivial): Let $\triangle ABC$ be a triangle. Let $\mathcal{H}_A$ be the hyperbola with foci at B and C, passing through A. Define $\mathcal{H}_B$ and $\mathcal{H}_C$ similarly. Then $\mathcal{H}_A,\mathcal{H}_B,\mathcal{H}_C$ meet at exactly two points unless $\triangle ABC$ is equilateral, in which they would meet at one point (which is the orthocenter=incenter=circumcenter in that case). I'm not very well-versed with conics, so I'm not sure how I would go about proving this. I tried using the basic definition of a hyperbola, and you get a system of three distance equations, which are quite tricky to solve. I then supposed that X is some point such that $|XA-XB|=|a-b|, |XB-XC|=|b-c|$ (the intersection of two of the hyperbolas), and then tossing this on the complex plane, setting X to be the origin. This didn't go so well. I don't believe any bashing approaches work, I think this problem requires some sort of projective transformation. Also, it's quite a simple conjecture, so it's likely well known, but I haven't been able to find it on the internet. All help is appreciated.

Can every even number be written as $(p-q)/6$ where p,q are primes?

For n even, assume $\large n = \frac{q-p}{6}$ For $a,b \in\mathbb{N}$, primes p,q can be written as $q = 6a\pm1$ $p = 6b\pm1$ There are 4 possible cases Case 1 $n = \frac{(6a-1)-(6b-1)}{6}$, then $n=a-b$ Case 2 $n = \frac{(6a-1)-(6b+1)}{6}$, then $n = a-b-1/3$ Case 3 $n = \frac{(6a+1)-(6b-1)}{6}$, then $n = a-b+1/3$ Case 4 $n = \frac{(6a+1)-(6b+1)}{6}$, then $n=a-b$ For Cases 2 and 3, n cannot be even because of $\pm 1/3$. For Cases 1 and 4, both result in $n=a-b$. Not sure how to proceed from here?

On the eighth powers $A^8+B^8=C^8+D^8$. Are there non-trivial solutions to it?

It's conjectured that there are no non-trivial solutions to the Diophantine equation: $$ A^8+B^8=C^8+D^8 $$ I was trying to play around with it using some substitutions.. In particular I first write it as: $A^8-D^8=C^8-B^8$. Then I replace (A,D,C,B) with $(p+q,p-q,r+s,r-s)$ to obtein the following: $$ p q (p^2 + q^2) (p^4 + 6 p^2 q^2 + q^4) = r s (r^2 + s^2) (r^4 + 6 r^2 s^2 + s^4) $$ Then I replaced (p,q,r,s) with $(ax+by,ax-by,cx+dy,cx-dy)$ to obtein: $$ a^8 x^8 - b^8 y^8 = c^8 x^8 - d^8 y^8 $$ or: $$ \frac{x^8}{y^8} = \frac{b^8-d^8}{a^8-c^8} $$ I was trying to substitute some values but I only manage to get trivial solutions.. I would like to find some values such that $(A,B)\not=(C,D)$. Any kind of suggestions would be much appreciated. Thanks in advance for your help! Some references I have already looked at: https://arxiv.org/pdf/math/0505629v2.pdf, https://www.jstor.org/stable/pdf/2007700.pdf?refreqid=excelsior%3A139ca229e2c0550603c138b5ada591c3&ab_segments=&origin=&acceptTC=1, https://sites.google.com/site/tpiezas/013 . EDIT 1: My last substituion is useless. I have just written (A,D,C,B) as (ax,by,cx,dy) in the end.. And there are no non-trivial solution in this case.

For every odd prime number $p \gt 3$ there exists another prime number $q \lt p$ such that $p - q = 2^n$ for some $n \geq 1$. Can you prove it?

Conjecture. Let p be an odd prime number greater than 3. Then there exists another odd prime number $q \lt p$ such that $p - q = 2^n$ for some positive exponent n. Can we prove this or is it another one of those simple to state, but almost impossible to prove, statements about prime numbers?

Find a Stirling-formula like for $(x!)!$

Hi working again on the gamma function I find that : let $0<x\leq 1$ and $1\leq k\leq \infty$ then define : $$f(x)=(x!)!,g(x)=\left(\left(x!\right)!\right)^{\frac{1}{e^{x^{k}}}}$$ Then a conjecture : It seems $\exists k\in(1,\infty)$ such that $g(x)$ admits an asymptote as $x\to \infty$. Then see here Trying to prove the Stirling approximation using concavity for $x\geq 1$ we can squeeze the function $f(x)$ and remains to determine some constant . If my conjecture is true how to achieve this ?

Are there conjectured closed forms for factorial rational zeta series?

Context At the bottom of this page from Wolfram Mathworld on the Riemann zeta function, the following constants are defined in equations (133), (137), and (141), respectively: \begin{align*} C_{1} &:= \sum_{n=2}^{\infty} \frac{\zeta(n)}{n!} \\ & \approx 1.07818872957581848275826543676983238170721 9, \\\qquad C_{2} &:= \sum_{n=1}^{\infty} \frac{\zeta(2n)}{n!} \\ & \approx 2.40744655479032851470948665622302272558 2266, \text{ and} \\ C_{3} &:= \sum_{n=1}^{\infty} \frac{\zeta(2n)}{(2n)!} \\ &\approx 0.86900199196290899881105480556139568889 2494.\end{align*} It is also stated that "These sums have no known closed-form expression". However, it could be the case that there are conjectured closed forms for these constants that correspond to the actual values with a high degree of accuracy. Question: Are there any of such conjectured closed forms for

C_{1}, C_{2}, and C_{3} ?

Proof-verification request: On the equation $\gcd(n^2,\sigma(n^2)) = D(n^2)/s(q^k)$

(Preamble: This question is an offshoot of this earlier post.) In what follows, denote the classical sum of divisors of the positive integer x by $\sigma(x)=\sigma_1(x)$, the deficiency of x by $D(x)=2x-\sigma(x)$, and the aliquot sum of x by $s(x)=\sigma(x)-x$. Let $N = q^k n^2$ be an odd perfect number with special prime q satisfying $q \equiv k \equiv 1 \pmod 4$ and $\gcd(q,n)=1$. Descartes, Frenicle, and subsequently Sorli conjectured that $k=1$ always holds. (In this proof-verification request, we shall attempt to prove this conjecture.) Using the fundamental equation $$\sigma(q^k)\sigma(n^2)=\sigma(q^k n^2)=\sigma(N)=2N=2q^k n^2$$ and using the fact that q^k and $\sigma(q^k)$ are relatively prime (that is, $\gcd(q^k,\sigma(q^k))=1$), then we get that $q^k \mid \sigma(n^2)$, whereupon we obtain that $$\frac{\sigma(n^2)}{q^k}=\frac{2n^2}{\sigma(q^k)}$$ is an odd integer. From the hyperlinked MSE question above, we have obtained the identities $$\gcd\bigl(n^2,\sigma(n^2)\bigr)=\frac{\sigma(n^2)}{q^k}=\frac{2n^2}{\sigma(q^k)}=\frac{D(n^2)}{s(q^k)}=\frac{2s(n^2)}{D(q^k)}.$$ Now, in a comment underneath MSE user Aravind's answer to the hyperlinked MSE question above, we derived that $$\gcd\bigl(n^2,\sigma(n^2)\bigr)=n^2 \bigl(q^k t - 2(q - 1)\bigr) + \sigma(n^2) \bigl(-(\sigma(q^k)/2)\cdot t + q \bigr), \tag{1}$$ where t is necessarily an integer to be determined by using the identity $$\gcd\bigl(n^2,\sigma(n^2)\bigr)=\frac{D(n^2)}{s(q^k)}. \tag{2}$$ Equating (1) and (2), we obtain $$\frac{D(n^2)}{s(q^k)}=n^2 \bigl(q^k t - 2(q - 1)\bigr) + \sigma(n^2) \bigl(-(\sigma(q^k)/2)\cdot t + q \bigr). \tag{3}$$ Multiplying both sides of (3) by $s(q^k)$, we obtain $$2n^2 - \sigma(n^2) = D(n^2) = n^2 \bigl(q^k s(q^k) t - 2(q - 1)s(q^k)\bigr) + \sigma(n^2) \bigl(- (\sigma(q^k)/2) s(q^k) \cdot t + q s(q^k) \bigr). \tag{4}$$ Equating coefficients for n^2 and $\sigma(n^2)$ in (4), we have that $$\begin{cases} 2 = q^k s(q^k) t - 2(q - 1)s(q^k) \\ -1 = - (\sigma(q^k)/2) s(q^k) \cdot t + q s(q^k) \end{cases} \tag{5} $$ The system in (5) is a set of two simultaneous "linear" equations in t, of the form $$\begin{cases} A t + B = 2 \\ C t + D = -1 \end{cases} \tag{6} $$ where $$A = q^k s(q^k), B = - 2(q - 1)s(q^k)$$ and $$C = - (\sigma(q^k)/2) s(q^k), D = q s(q^k).$$ We now solve the system (6) for t. We thereby get $$\begin{cases} 2D = ADt + BD \\ B = -BCt - BD \end{cases} \tag{7} $$ Adding the two equations in (7), we obtain $$2D + B = (AD - BC)t$$ $$t = \frac{2D + B}{AD - BC}.$$ But $$2D + B = 2qs(q^k) - 2(q - 1)s(q^k) = s(q^k)\bigl(2q - 2(q - 1)\bigr) = 2s(q^k) \tag{8}$$ and $$AD - BC = q^{k+1} \bigl(s(q^k)\bigr)^2 - (q - 1)\sigma(q^k) \bigl(s(q^k)\bigr)^2 = \bigl(s(q^k)\bigr)^2 \bigl(q^{k+1} - (q - 1)\sigma(q^k)\bigr) $$ $$= \bigl(s(q^k)\bigr)^2 \bigl(q^{k+1} - (q^{k+1} - 1)\bigr) = \bigl(s(q^k)\bigr)^2. \tag{9}$$ Consequently, from (8) and (9), the variable t (which is necessarily an integer) must have the value $$t = \frac{2D + B}{AD - BC} = \frac{2s(q^k)}{\bigl(s(q^k)\bigr)^2} = \frac{2}{s(q^k)}.$$ Since $s(q^k) \geq 1$ holds in general, then t is an integer implies that either $s(q^k) = 1$ or $s(q^k) = 2$. Want to show: $s(q^k) = 1$ Assume to the contrary that $s(q^k) = 2$. This is equivalent to $$q^k - 1 = 2(q - 1)$$ $$q^k - 2q = -1$$ $$2q - q^k = 1$$ $$q\bigl(2 - q^{k-1}\bigr) = 1$$ This implies that $q = 1$ AND $2 - q^{k - 1} = 1$, from which we obtain $1 = q^{k - 1}$ and $q = 1$. The first equation implies that $k = 1$, while the second condition contradicts q being the special prime satisfying $q \equiv 1 \pmod 4$ (so that $q \geq 5$). Hence, necessarily we have $s(q^k) = 1$, or $k = 1$. Here is my question: Is the method of equating coefficients for n^2 and $\sigma(n^2)$ in (5) a valid approach?

Show that: $e^{\pi}-\pi^{e} >\frac12$ without calculator

Show that: $$e^{\pi}-\pi^{e} >\frac12$$ I am not sure, if anything can be done using elementary methods. Because e and π are not algebraic numbers. Therefore, I find it impossible to prove this with elementary techniques. Maybe using the elementary formula $\left(1+\frac 1n\right)^n\rightarrow e$ for e would work. But there is no such formula for π. I guess there is no other way than using series, right?

Express any positive integer as $\lfloor (\sqrt\ )^m (4(!^n))\rfloor$?

For some reason, I recently recalled a math puzzle column from many years ago about expressing integers in terms of some number of fours. The column noted that there was a conjecture to the effect that every positive integer can be expressed as $\left\lfloor\overbrace{\sqrt{\ \ldots \sqrt{4\underbrace{!\ \ldots\ !}_{n\text{ factorials}}}}}^{m\text{ square roots}}\right\rfloor\tag*{}$ for some non-negative (or was it positive?) integers m and n (possibly in more than one way). For instance, $5 = \left\lfloor\sqrt{\sqrt{\sqrt{\sqrt{\sqrt{4!!\,}}}}}\right\rfloor.\tag*{}$ Has any progress been made on this conjecture in the last 40 or so years? How would one even approach the general case? What about if 4 is replaced by some other integer greater than 2?

A useful way of characterizing primes?

It's proved that if $P(n)$ is the sum of all different prime factors of n, then for all odd primes p there is an inequality $$p\ge P(p^2-1)$$ An inequality holding for odd primes Therefore there is an injection $j:\mathbb P \to \mathbb Q$, defined as $j(p)=\frac{p}{P(p^2-1)}$. Now to me the following conjecture seems very natural: Given $\varepsilon >0$ there are two primes p,q such that $|j(p)-j(q)|<\varepsilon$ The idea is to characterizing primes p by the factorizations of their neighbors $p-1,p+1$. A metric on the prime numbers? $d(p,q)=|j(p)-j(q)|$ seems to fulfill the triangle inequality. Tested for all combinations of the 100 first primes. I now realize that d must be a metric because j is an injection. It is possible to define convergence of sequences of primes.

Every onto map f such that $f(xy)=f(x)+f(y)+f(x)f(y)$,$f : \Bbb{Z}\setminus 0 \to\Bbb{Z}/2$ is represented by some prime number p and $f=(p\mid-)$

Let $(n \mid x)$ mean 1 if $n \mid x$ and 0 otherwise. Let $f = (p\mid -)$ then $f: \Bbb{Z}\setminus 0 \to \Bbb{Z}/2$ is surjective and only satisfies $$f(xy) = f(x) + f(y) + f(x)f(y), \ \forall x,y \in \Bbb{Z}\setminus 0$$ because p is a prime number. I.e. if p were not prime then it would fail to hold that when $p\mid xy$ then $p \mid x$ or $p\mid y$ in general. The surjectivity part rules out $p = 0, 1$. I'm wondering if a converse is true, i.e. for any such surjective map f, does there exist a prime p such that $f = (p \mid -)$?

If p can divide $a^n+b^n+c^n$, can p^k divide it as well?

Related to this Is there a method to decide whether a given function of the form $f(n)=a^n+b^n+c^n$ (a,b,c fixed positive integers , n running over the positive integers) satisfies the following property : If p is a prime number with $p\mid f(s)$ for some positive integer s and k is any positive integer , then there is a positive integer t with $p^k\mid f(t)$. In other words , if a prime can divide this expression, every power of this prime can it as well. I am particular interested in the case $(a,b,c)=(5,6,10)$, so $f(n)=5^n+6^n+10^n$ because in this case my prime search revealed a probable prime quite late (for $n=3168$) , but no other probable prime upto $n=60\ 000$. Furthermore I try to factor numbers of this form the last months (see the linked question) I tried to use that $p\mid f(n)$ is equivalent to $p\mid u^n+2^n+1$ where u is one of $\frac{p+6}{5},\frac{2p+6}{5},\frac{3p+6}{5},\frac{4p+6}{5}$ depending on which of those is an integer. But this led to nowhere. For this special case $(a,b,c)=(5,6,10)$ I found out the following : For $p\le 2\cdot 10^5$ and $k=2$ the conjecture is true. For $p\le 14\ 000$ and $3\le k\le 5$ the conjecture is true.

Is this conjecture well-formed?

For each positive integer n, one of these is true, where $a,b,c,...etc.$ are natural numbers: $$ \begin{array}{l} 3^0\cdot{n}=2^a\\ 3^1\cdot{n}=2^a-(3^0\cdot2^b)\\ 3^2\cdot{n}=2^a-(3^0\cdot2^b)-(3^1\cdot2^c)\\ 3^3\cdot{n}=2^a-(3^0\cdot2^b)-(3^1\cdot2^c)-(3^2\cdot2^d)\\ ... etc. \end{array} $$ (The specific values of $2^a, 2^b, 2^c, ...etc.$ dependent on n, e.g. all powers of two satisfy $3^0\cdot{n}=2^a$ for some value of a) Or, more succinctly: $$ \forall{n}\in\mathbb{N}^+\exists{x}\in\mathbb{N}:n={2^{a_x}+\sum\limits_{y=0}^{x-1}-(3^y\cdot2^{a_y})\over3^x} $$

$\sum{x^{(i,n)}}+1$ is irreducible?

A simple calculation using Burnside lemma shows that the number of distinct "necklaces" with n balls of x colors is $$\frac{F_n(x)}{n} = \frac{\sum_{i=1}^n x^{(i,n)}}{n} = \frac{\sum_{d \mid n} x^d \varphi\left(\frac{n}{d}\right)}{n}.$$ It's natural to ask more about this polynomial F_n. A few attemptions shows that $F_n + 1$ might be irreducible over $\mathbb Q$: $$ F_2(x) + 1 = x^2 + x + 1,\\ F_3(x) + 1 = x^3 + 2x + 1,\\ F_4(x) + 1 = x^4 + x^2 + 2x + 1,\\ \cdots $$ In fact, a computer search up to F_{2000} shows that F_i is irreducible for all $i \le 2000$. QUESTION. Is F_n+1 irreducible over $\mathbb Q$ for all $n \ge 2$?

Prove or disprove: If $f(x)$ is continuous in $(0,1]$ and $f(x)\to\infty$ as $x\to 0^+$, then $\lim_{n\to\infty}\sum_{k=1}^n f(k/n)$ does not exist.

I'm trying to prove or disprove the following conjecture: If $f(x)$ is continuous in $(0,1]$ and $f(x)\to\infty$ as $x\to 0^+$ then $L=\lim\limits_{n\to\infty}\sum\limits_{k=1}^n f\left(\frac{k}{n}\right)$ does not exist. My attempt I tried proof by contradiction. Asssume L exists. $L=\lim\limits_{n\to\infty}n(\frac{1}{n})\sum\limits_{k=1}^n f\left(\frac{k}{n}\right)=\left(\lim\limits_{n\to\infty}n\right)\int_{0}^1 f(x)dx$ (EDIT: As mentioned by @FShrike in the comments, the previous step is not valid.) $\therefore \int_{0}^1 f(x)dx=0$ There are functions $f(x)$, continuous in $(0,1]$, such that $f(x)\to\infty$ as $x\to 0^+$ and $\int_{0}^1 f(x)dx=0$. For example, $f(x)=-\ln{x}-1$, in which case L does not exist, by Stirling's approximation. But I do not see why all such functions $f(x)$ would imply that L does not exist. Context: I am interested in geometrical infinite products (example1, example2). The conjecture in this question, via the substitution $f(x)=-\ln{g(x)}$, is equivalent to: If $g(x)$ is continuous in $(0,1]$ and $\lim\limits_{x\to 0^+}g(x)=0$ then

$\lim\limits_{n\to\infty}\prod\limits_{k=1}^ng\left(\frac{k}{n}\right)$ either equals 0 or does not exist, which stands in interesting contrast with the fact that infinite products of lengths or areas, that tend to 0, can equal a positive number. EDIT2: I'm not sure if this is helpful, but I have noticed that $L_2=\lim\limits_{n\to\infty}\sum\limits_{k=1}^n f\left(\frac{k-1/2}{n}\right)$ can exist. For example, $\lim\limits_{n\to\infty}\sum\limits_{k=1}^n \left(-\ln{\left(\frac{k-1/2}{n}\right)}-1\right)=-\frac{\ln{2}}{2}$. (Another question of mine yielded methods for dealing with the sum $\sum\limits_{k=1}^n \ln{(k-\frac12)}$.) I do not understand why replacing k with $k-\frac12$ seems to make the limit existable (if that's a word).

Find conjugate function

$A\in R^{m\times n},\ rankA = m,\ f(y) -\text{ Convex function,} \ f:R^m\rightarrow R.$ Let $g(x) = f(Ax)$ Find $g^*(y)$. Because$x\rightarrow Ax$ - Affine transformation $\implies g(x)$ - is convex as well. Because $rank{A}=m \implies g:R^m \rightarrow R$. Because $g(x)$ is convex upwards $-g(x)$ is convex downwards and has sup (only one). Let's notice that $<x,y> - g(x)$ is also convex downwards. $$k(x,y)=<x,y>-g(x)$$ $$k_x'(x,y)=\bar{y}-\nabla g(x)=\bar{y}- A^T\nabla f(Ax)=0$$ $$\nabla f(Ax) = (A^T)^{-1}y$$ $$g^*(y) = \sup_{R^m}{k(x,y)}=<x,y>-...$$ How can I precede starting from this moment?

Calculation of generalized Artin's constants

Let $T(p)$ be the period of the decimal expansion of $1/p$, for prime p (e.g. $1/7=0.\overline{142857}\rightarrow T(7)=6$). It is known that $$T(p)=\frac{p-1}{t}$$ for some integer t. Then, Artin's conjecture states that the fraction of primes for which $t=1$ is positive and is given by Artin's constant: $$ A_1=\lim_{x\rightarrow\infty}\frac{\#\{p:\frac{p-1}{T(p)}=1\text{ } \ {\rm and } \ p\leq x\}}{\#\{p:p\leq x\}}=\prod_{p} \left(1-\frac{1}{p(p-1)}\right)=0.3739558136... $$ Artin's constant can be generalized by considering the fraction A_t of primes that satisfy some arbitrary t. My question is: Is there some known formula to calculate it for any t? By searching about the subject, I found some articles that seem to give expressions for that, but they are quite hard to read and understand. Ram Murty in this article and Wagstaff in this one seem to imply that $$A_t=\frac{A_1}{t^2}\prod_{p\mid t}\left(\frac{p^2-1}{p^2-p-1}\right)$$ But by considering the first 1,000,000 primes, it doesn't seem to give the correct result for some values of t, such as $t=40$. So, in addition to the first question, what are the limitations of the above formula?

How proof The shape of the two hearts in $\mathcal{D}^b(A_n)$ is the same if the graded undergrphas of the Ext quiver of heart of are equal

According to Yu Qiu 's Ext-quivers of hearts of A-type and the orientation of associahedron, We know hearts in $\mathcal{D}^b(A_n)$ one by one corresponds to the Ext quivers and are precisely the associated quivers of graded gentle trees with n vertices. And it's not hard to noticed if two hearts if the shapes are equal then the inverse proposition of the proposition in the title holds. Absolutely,the proposition and inverse proposition is trivia and I have proven the inverse proposition. But I can't find a simple proof to describe the title. Example in $\mathcal{D}^b(A_3)$,A_3 has straight orientation, $\mathcal{H}_1=<S_1,S_2,S_3>$,$\mathcal{Q}(\mathcal{H}_1)=S_1\xrightarrow{1}S_2\xrightarrow{1}S_3$ $\mathcal{H}_2=<S_1[-1],P_1,S_3[1]>$,$\mathcal{Q}(\mathcal{H}_1)=S_3[1]\xrightarrow{1}P_1\xrightarrow{1}S_1[-1]$ the under graph of ext quiver are $\bullet\xrightarrow{1}\bullet\xrightarrow{1}\bullet$, The two heart has the same shape (A positive triangle, an inverted triangle) Question: My main problem is that when n is large enough, Ext quiver itself will start to get complicated, and simply using Hom discussion is extremely tedious.Do we have a good idea or lemma to solve it Thanks for everyone! Remark: Let $\mathcal{H}$ be a finite heart in a derived category $\mathcal{D}^b(A_n)$. The Ext-quiver $\mathcal{Q}(\mathcal{H})$ is the (positively) graded quiver whose vertices are the simples of $\mathcal{H}$ and whose degree k arrows $S_i\rightarrow S_j$ correspond to a basis of $\mathrm{Hom}_\mathcal{D}(S_i,S_j[k])$.

Is this stronger conjecture about near-rep digit prime numbers true?

Inspired by this post, I established an even stronger conjecture: If we have the number $1\ldots 1$ with $k\ge 3$ digits 1 in decimal expansion, then we can replace a digit which is neither the first nor the last by one of $2,3,\ldots ,9$, to get a prime number. More mathematically formulated Let $k\ge 3$ be an integer. Then, there exists an integer j with $1\le j\le k-2$ and an integer m with $1\le m\le 8$, such that $$\frac{10^k-1}{9}+m\cdot 10^j$$ is prime (which is a near-rep digit prime number as desired in the question). This is a significant strengthening of what is asked in the question. Heuristic: The desired prime is roughly 10^{k-1}, a random number with approximately this magnitude is prime with probability about $\frac{1}{\ln(10)\cdot (k-1)}$ and since we have the choice of $8\cdot (k-2)$ numbers, for $k\ge 1000$, the expected number of primes is about 3.47. Computational result: The conjecture is true upto $k=1000$ (I proved the primality of the found examples until $k=500$, for the rest of the range the very realiable BPSW-test was used). Any idea, reference or extension of the search limit would be very welcome.

Any "reasonable" and "natural" false graph theory conjectures for which the Petersen graph is not a counterexample?

I heard that the Petersen graph is a good test of a graph theory conjecture. As in, if you want to know whether a graph theory conjecture is false, the Petersen graph is likely to be a counterexample. So, with that in mind, are there any "reasonable" and "natural" graph theory conjectures, which is false, but for which the Petersen graph is NOT a counterexample? I would like a list of several such conjectures. Note, I do not have a formal definition of "reasonable" or "natural", but I know it when I see it.

If n is square-free and $n+1 \mid \sigma(n)$, is n a prime?

As the title says, is n being square-free together with $n+1 \mid \sigma(n)$ sufficient to show n is prime? It is well-known that if $\varphi(n)\mid n-1$ and $n+1 \mid \sigma(n)$, then n is a prime (see e.g. An integer is prime iff $\phi(n) \mid n-1$ and $n+1 \mid \sigma(n)$). Also it is a well-known open problem - Lehmer's totient problem - whether $\varphi(n)\mid n-1$ itself implies that n is a prime. Since $\varphi(n)\mid n-1$ implies that n is square-free, this makes me wondering what is known about the problem in between these two, i.e. n being square-free together with $n+1 \mid \sigma(n)$. I've checked by brute force that the conjecture holds up for n being a product of any of the first 31 primes. As for the proof, we can rule out product of two primes easily as $n=pq$ and $pq+1\mid \sigma(n)=(p+1)(q+1)=pq+p+q+1$ implies $pq+1\mid p+q$ and then we show $pq+1>p+q$ contradicts this result. But it does not seem to generalize to more primes that simply. It might be also that this problem is open, in that case I have yet to find a reference. Update: I've found a proof that only even n that satisfies the conditions is $n=2$, pushing the possible counterexample to odd numbers only. To see this let $n=2\prod_{i=1}^{k} p_i$ where $p_i=2^{e_i}d_i-1$ with $e_i \geq 1$ and d_i odd. Now we have two possibilities, either $e_i=1$, or $e_i \geq 2$. If $e_i=1$, then $d_i \geq 3$, and we have $$ 2^{e_i}d_i-1 \geq 2d_i-1\geq \sqrt[k]{\frac{3}{2}} d_i $$ where the last inequality follows from $(2-\sqrt[k]{\frac{3}{2}})d_i\geq (2-\sqrt[k]{\frac{3}{2}})3\geq 1$, which holds for $k \geq 1$. If on the other hand $e_i\geq 2$, then $$ 2^{e_i}d_i-1 \geq 4d_i-1\geq \sqrt[k]{\frac{3}{2}} d_i $$ this time because $(4-\sqrt[k]{\frac{3}{2}})d_i\geq (4-\sqrt[k]{\frac{3}{2}})\cdot 1\geq 1$, which again holds for $k \geq 1$. Either way we get $2^{e_i}d_i-1\geq \sqrt[k]{\frac{3}{2}} d_i$. But then $$ n+1=2\prod_{i=1}^{k}(2^{e_i}d_i-1)+1\geq 2 \prod_{i=1}^k \sqrt[k]{\frac{3}{2}} d_i +1=3\prod_{i=1}^{k}d_i+1 $$ and at the same time $$ n+1\mid\sigma(n)=(2+1)\prod_{i=1}^{k} 2^{e_i}d_i=3\cdot 2^{\sum e_i}\prod_{i=1}^k d_i. $$ Since $n+1$ is odd, we have $n+1 \mid 3\prod_{i=1}^k d_i$ and so $n+1 \leq 3\prod_{i=1}^k d_i$. But these results are contradictory as we have $$ 3\prod_{i=1}^{k}d_i+1\leq n+1 \leq 3\prod_{i=1}^k d_i. $$ Update 2: Furthermore any counterexample must have $n \equiv 3 \pmod 4$. This follows from C.S.'s argument in the linked answer: If $4\mid n-1$, then $2\mid n+1$ and $4\nmid n+1$. So $v_2(n+1)=1$. If n has k odd prime factors then $2^k \mid \sigma(n)$. But then $2^{k-1}\mid \frac{\sigma(n)}{n+1}$ and in turn $$ 2^{k-1}\leq \frac{\sigma(n)}{n+1}<\frac{\sigma(n)}{n}=\prod_{p\mid n} \frac{p+1}{p}\leq \prod (1+\frac{1}{3})=\Big(\frac{4}{3}\Big)^k $$ which does not hold for $k \geq 2$, so $k=1$ and n is a prime.

Conjecture: Prove that, $\forall (m,n,k)\in\Bbb Z_{>0}^{3}$ there exists $x\in \Bbb Z_{>0}$, such that: $m^x \equiv x^n\pmod k$

Conjecture: Prove that, $\forall (m,n,k)\in\Bbb Z_{>0}^{3}$ there exists $x\in \Bbb Z_{>0}$, such that: $$m^x \equiv x^n\pmod k$$ The conjecture seems correct. Also this conjecture is possible generalization of the known conjecture. If $m=1$. Then the conjecture is trivial. We have $x^n-1\pmod n$. Then the smallest x equals to $x=n+1$. Because, $x-1\mid x^n-1^n$. The $n=1$ case has been proven before. I tried to solve the general case using the induction, but the induction didn't worked. But, I have many computational results. I chose big prime numbers to check the conjecture. Let $m=31$, $n=17, k=59$. I don't have a software. I've experimented with Wolfram as much as I can. Here is the my input: Table (31^x-x^17)/59 , x=1 to 100 I found that the smallest x equals to 99. These are the things I can do.

Is 650 the only solution not fitting in the family?

Inspired by this question The linked question conjectures that $\frac{\sigma(n)}{n+1}$ (where $\sigma(n)$ denotes the divisor-sum function) is not an integer for any squarefree composite number. If we drop the condition that n is squarefree , there are still not many solutions. There is a (perhaps infinite) family of solutions , namely $$n=2^m\cdot (2^{m+1}-3)=2^{2m+1}-3\cdot 2^m$$ where $2^{m+1}-3$ is prime. In this case we have $$\sigma(n)=(2^{m+1}-1)(2^{m+1}-2)=2^{2m+2}-3\cdot 2^{m+1}+2=2(n+1)$$ The only solution I found so far that does not fit into this family is $$650=2\cdot 5^2\cdot 13$$. Current search limit is $n=10^9$ Is this the only such solution ? Since the linked question is still open , this won't be easy , but can we at least solve the case that n is not squarefree ? Has this perhaps already been verified ? If yes, a reference would be nice.

Filling space with polycube snakes

One of Martin Gardner's "Mathematical Games" columns (Scientific American June 1981, pp24-29; reprinted in The Last Recreations (1997), pp274-283, and The Colossal Book of Mathematics (2001) pp203-211) describes the following problem due to Scott Kim: First we must define a snake. It is a single connected chain of identical unit cubes joined at their faces in such a way that each cube (except for a cube at the end of a chain) is attached face to face to exactly two other cubes. The snake may twist in any possible direction, provided no internal cube abuts the face of any cube other than its two immediate neighbors. The snake may, however, twist so that any number of its cubes touch along edges or at corners. A polycube snake may [...] have just one end and be infinite in length, or it may be infinite and endless in both directions. We now ask a deceptively simple question. What is the smallest number of snakes needed to fill all space? We can put it another way: Imagine space to be completely packed with an infinite number of unit cubes. What is the smallest number of snakes into which it can be dissected by cutting along the planes that define the cubes? [...] Kim has found a way of twisting four infinitely long one-ended snakes into a structure of interlocked helical shapes that fill all space. The method is too complicated to explain in a limited space; you will have to take my word that it can be done. [...] Kim has conjectured that in a space of n dimensions the minimum number of snakes that completely fill it is $2(n-1)$, but the guess is still a shaky one. In the reprints (I can't find this ever printed in the Scientific American back issues, but maybe I missed it), Gardner adds: Dr. Koh Chor Jin, a physicist at the National University of Singapore, sent a clever proof that given a finite volume of space it is possible to cover it with two of Kim's cube-connected snakes. However, as Kim pointed out, Jin's construction does not approach all of space as a limit [...] So my question for StackExchange is: What was Scott Kim's (or, what is a) four-snake space-filling construction? And what was Koh Chor-Jin's (or, what is a) way to cover any finite volume with two snakes? This guy is also looking for information on the problem. Footnote: At first I wondered if $2(n-1)$ was a typo for 2^{n-1}, since obviously it takes one snake (not zero snakes) to fill 1-space. But it's consistently typeset as $2(n-1)$ in all three primary sources, so I think the "for $n\ge 2$" is implied.

Regular polygon of radius 1 with diagonals: mysterious ring of radius $1/e$?

I was playing with a geogebra applet that shows regular n-gons of radius 1 with their diagonals. For example, here is the 12-gon with its diagonals: For any value of n, when I shrink the image, the image becomes darkened (due to the thickness of the lines), but sometimes there remains a faint single white ring, indicating a ring of exceptionally large cells. For example: $n=20$ $n=45$ $n=50$ Now here's the interesting thing: The radius of the white ring always seems to be approximately $1/e$. (I used Perfect Screen Ruler.) For some n-values, I cannot perceive a single white ring; I guess it still exists but is not perceivable due to limitations in pixelation and/or visual acuity. I can formalize my conjecture as follows: In a regular n-gon of radius 1 with it diagonals, if $d_n=$ distance between the centre and the centroid of one of the cells with the greatest area (excluding the centre cell when n is odd), then $$\lim\limits_{n\to\infty}d_n=\frac{1}{e}$$ Question: Is my conjecture true? (This question was inspired by another question: Distribution of areas in regular n-gon with diagonals, as $n\to\infty$.)

Why is it not known that $\sum_{n>0}\frac{(-1)^nn}{p_n}$ converges?

No one knows if this sum $$\sum_{n>0}\frac{(-1)^nn}{p_n}$$converges (where p_n is the nth prime). But what makes proving this so hard? We know that $$\bigg|\sum_{n>0}\frac{(-1)^n}{p_n}\bigg|<\frac{1}{2}$$converges and is similar to the other sum. Remark: Apparently: $$\sum_{n>2}\frac{(-1)^n}{\pi(n)}$$converges, where $\pi(n)$ is the prime counting function.

Conjecture about the representation of a constant $C=0.6516...$

It's a follow up of my previous question How to find the constant C such that $f(x)\geq Cx$: We start with : $$\left|\exp\left(1-\prod_{k=1}^{1000}\left(1-\frac{1}{2^{k}(k+1)}\right)\right)-\sqrt{2}-\frac{1}{2^{9}}-\frac{1}{2^{11}}-\frac{1}{2^{14}}-\frac{1}{2^{16}}+\frac{1}{2^{18}}-\frac{1}{2^{20}}-\frac{1}{2^{21}}-\frac{1}{2^{24}}+\frac{1}{2^{27}}+\frac{1}{2^{30}}-\frac{1}{2^{33}}+\frac{1}{2^{36}}+\frac{1}{2^{38}}+\frac{1}{2^{39}}-\frac{1}{2^{41}}\right|<4*10^{-13}$$ Conjecture If $a_n\in N_{\geq 9}$: $$\exp\left(1-\prod_{k=1}^{\infty}\left(1-\frac{1}{2^{k}(k+1)}\right)\right)=\sqrt{2}+\sum_{n=1}^{\infty}\pm\frac{1}{2^{a_n}}$$ I want to show that : $$a_{n+1}>a_n$$ $$10>a_{n+1}-a_n$$ The $\pm$ means it's either positive or negative . I have tried until $n=50$ without a counter-example . As in my answer using the exponent I don't find it in oeis . The a_n seems also steady enought to believe in this conjecture .I have tried also to represent the power of two with an integral without a significant result .For example we have : $$\int_{0}^{1}-\ln\left(x^{\frac{1}{2^{n+1}}}\left(1-x\right)^{\frac{1}{2^{n+1}}}\right)dx=1/2^n$$ We can also speak about the (ir)rationality of C. Question : How to (dis)prove it ? Thanks in advance .

Given the 2^n primorial divisors, $D(5\#) = \{ 1, 2, 3, 5, 6, 10, 15, 30\}$, why are there always exactly 2^n different divisor indicator vectors?

Define $D(m)$ to be the (ordered) set of divisors of $m \in \Bbb{N}$. Let $m = p_n\# = 1 \cdot 2 \cdot 3 \cdot 5 \cdots p_n$. Clearly, $|D(m)| = $ the number of divisors of $p_n\# = 2^n$. Now define a divisor indicator vector at x to be $\langle (d \mid x) : d \in D(m) \rangle$ where $(d \mid x) = \begin{cases} 1, \text{ if } d \mid x \\ 0, \text{ if } d \nmid x \end{cases}$; for any given $x \in \Bbb{Z}$. Conjecture 1. The number of possible divisor indicator vectors is precisely 2^n. For example: 1 2 3 5 6 10 15 30 1 0 0 0 0 0 0 0 1 1 0 0 0 0 0 0 1 0 1 0 0 0 0 0 1 0 0 1 0 0 0 0 1 1 1 0 1 0 0 0 1 1 0 1 0 1 0 0 1 0 1 1 0 0 1 0 1 1 1 1 1 1 1 1 I.e. there are 8 divisors so the number of divisor indicator vectors is also 8. Clearly it's since if $15 \mid x$ then both $3 \mid x$ and $5\mid x$ and vise-versa, since $\gcd(3,5) = 1$, but how would the argument go for the general case? My next question which I think is better is about this conjecture: Conjecture 2. The set of all possible divisor indicator vectors is linearly independent over any field. I say any field because every field by definition contains the values of the divisor indicator $(d \mid \cdot)$ or 0 and 1. So for each field F you'd define $(d\mid \cdot) : \Bbb{Z} \to \{0, 1\} \subset F$. Now this might have something to do with the first conjecture since our degrees of freedom are precisely determined by the n primes involved and taken together (just the prime components): 2 3 5 1 0 0 0 1 0 0 0 1 we have clear linear independence. What is the easiest & most elegant way you can think of to prove both of these conjectures?

Graphs with all vertices having more neighbors than 2nd order neighbors

This is the conjecture that inspired my question: https://en.wikipedia.org/wiki/Second_neighborhood_problem For any vertex v, let $N(v)$ be the set of vertices adjacent to v and let $N^2(v)$ the set 2nd order neighbors, thus all vertices that have a distance of exactly 2 relative to v. The conjecture concerns directed graphs, but I was interested in undirected simple graphs with each vertex having strictly more neighbors than second order neighbors. A basic example would be a graph of 4 vertices, completely connected except for one edge. I believe such graphs are exactly the ones that have the following characteristic: for each vertex v, more than half of all possible 2-step walks starting from v have an endpoint in $N(v)$ So far I haven't encountered a counter example but neither can I prove it, it's somewhat intuitive but not completely. Would love to hear your thoughts.

Do all Turing-complete systems converge on a single universal function w.r.t. description redundancy?

Let L be any Turing-complete language. Let $d_L(n)$ be the number of distinct algorithms expressible in L using at most n bits. I'm not sure how to properly define "distinct algorithm", but broadly it's what you would expect: multiple halting programs returning the same value are considered equivalent to one another, as are cyclic programs stepping through the same sequence, as are runaway programs exhibiting identical growth. I assert that $$\frac{d_L(n)}{n} \to D(n)\qquad\text{as }n \to \infty,$$ where D is some unknown but very real function. I would imagine D is nearly or completely uncomputable, and perhaps monotonically increasing with n. Most importantly, I assert this holds regardless of choice of L, in contrast to Ω_L and related functions. The short version of my reasoning for this claim is that it is an immediate consequence of the no free lunch theorem, which states that over a uniform distribution of all possible binary strings, no compression algorithm will outperform any other. My understanding is that it's equivalent or similar to the principle that there is no such thing an ideal optimizing compiler (the "full-employment theorem"). In this case, since any candidate language L is aggregating its results over all possible binary strings up to length n, no one language should be able to come out ahead in terms of economy of representation. This should also be apparent by a simple counting argument. This means that, in general, any choice of L will encode the same total number of bits after running it over all $2^n -1$ possible descriptions. However, I think it may be the case that that only holds perfectly when the encoding is perfectly efficient, as for example with universal prefix-free languages. Even if I've gotten that wrong, thanks to Kolmogorov invariance there will be some constant c (given a finite set of languages) such that $$d_{L_1}(n) \leq d_{L_2}(n) \leq d_{L_1}(n+c)$$ for any choice of L_1,L_2. This provides a bound of $$2^{-c} \leq \frac{d_{L_2}(n)}{d_{L_1}(n)} \leq 2^c.$$ Since c should become negligible as n grows without bound, I would expect that to converge to 1 in the long run, which would imply that the number of distinct descriptions between languages do indeed all approach some single curve $D(n)$ in the limit. While I can't back this argument up formally yet, I see only one potential issue with it; D may be dependent on the set of languages being used. I'm not clear on whether that is likely to be true, but even if it is, so long as you don't let the set of languages grow without bound, the distinct-description proportions should still converge to a single curve. My question: Does this sound generally right, or am I off track? If right, I assume it's a known result and would appreciate a keyword to hunt for. If not, where did I go awry or what is unclear?

Conjecture about difference of Fibonacci numbers and primes

I'm curious to see if this conjecture is true: if $ m > 4 $ is a positive integer not divisible by $ 2 $ or $ 3 $, it's possible to find a positive integer $ n $ such that the difference of the $ 2 $ Fibonacci numbers $ F_{m+n}-F_n $ is a prime number. Various example of $ [m, n] $, with the smallest n, are $[5,3],[7,3], [11,4], [13,5], [17,3],..., [619,1353]...$ I don't know if this could be of any help: I converted the primes I found that way in the Zeckendorf representation and they are an alternating sequence of $ 1 $ and $ 0 $ ending with two adjacent $ 0 $ and $ 1 $ (and eventually just various $ 0 $) Edit: I posted this problem on Mathoverflow too

Every twin prime average $x \gt 6$ is the sum of two twin prime averages (Code checked up to $x \leq 1,000,000$).

If p,q are a pair of twin primes, then $x = \dfrac{p+ q}{2} = q-1 = p+1$ is their twin prime average. Conjecture. Every twin prime average $x \gt 6$ is the sum of two smaller twin prime averages, $x = x' + x''$. This doesn't require infinitude. So wondering if we can prove it. 12 = 6 + 6 18 = 6 + 12 30 = 12 + 18 42 = 12 + 30 60 = 18 + 42 72 = 12 + 60 102 = 30 + 72 108 = 6 + 102 138 = 30 + 108 150 = 12 + 138 180 = 30 + 150 192 = 12 + 180 198 = 6 + 192 228 = 30 + 198 240 = 12 + 228 270 = 30 + 240 282 = 12 + 270 312 = 30 + 282 348 = 108 + 240 420 = 72 + 348 432 = 12 + 420 462 = 30 + 432 522 = 60 + 462 570 = 108 + 462 600 = 30 + 570 618 = 18 + 600 642 = 42 + 600 660 = 18 + 642 810 = 150 + 660 822 = 12 + 810 828 = 6 + 822 858 = 30 + 828 882 = 60 + 822 1020 = 138 + 882 1032 = 12 + 1020 1050 = 18 + 1032 1062 = 12 + 1050 1092 = 30 + 1062 1152 = 60 + 1092 1230 = 138 + 1092 1278 = 228 + 1050 1290 = 12 + 1278 1302 = 12 + 1290 1320 = 18 + 1302 1428 = 108 + 1320 1452 = 150 + 1302 1482 = 30 + 1452 1488 = 6 + 1482 1608 = 180 + 1428 1620 = 12 + 1608 1668 = 60 + 1608 1698 = 30 + 1668 1722 = 102 + 1620 1788 = 180 + 1608 1872 = 150 + 1722 1878 = 6 + 1872 1932 = 60 + 1872 1950 = 18 + 1932 1998 = 570 + 1428 2028 = 30 + 1998 2082 = 150 + 1932 2088 = 6 + 2082 2112 = 30 + 2082 2130 = 18 + 2112 2142 = 12 + 2130 2238 = 108 + 2130 2268 = 30 + 2238 2310 = 42 + 2268 2340 = 30 + 2310 2382 = 42 + 2340 2550 = 240 + 2310 2592 = 42 + 2550 2658 = 108 + 2550 2688 = 30 + 2658 2712 = 570 + 2142 2730 = 18 + 2712 2790 = 60 + 2730 2802 = 12 + 2790 2970 = 180 + 2790 3000 = 30 + 2970 3120 = 150 + 2970 3168 = 198 + 2970 3252 = 282 + 2970 3258 = 6 + 3252 3300 = 42 + 3258 3330 = 30 + 3300 3360 = 30 + 3330 3372 = 12 + 3360 3390 = 18 + 3372 3462 = 72 + 3390 3468 = 6 + 3462 3528 = 60 + 3468 3540 = 12 + 3528 3558 = 18 + 3540 3582 = 42 + 3540 3672 = 282 + 3390 3768 = 228 + 3540 3822 = 150 + 3672 3852 = 30 + 3822 3918 = 150 + 3768 3930 = 12 + 3918 4002 = 72 + 3930 4020 = 18 + 4002 4050 = 30 + 4020 4092 = 42 + 4050 4128 = 108 + 4020 4158 = 30 + 4128 4218 = 60 + 4158 4230 = 12 + 4218 4242 = 12 + 4230 4260 = 18 + 4242 4272 = 12 + 4260 4338 = 108 + 4230 4422 = 150 + 4272 4482 = 60 + 4422 4518 = 180 + 4338 4548 = 30 + 4518 4638 = 420 + 4218 4650 = 12 + 4638 4722 = 72 + 4650 4788 = 138 + 4650 4800 = 12 + 4788 4932 = 282 + 4650 4968 = 180 + 4788 5010 = 42 + 4968 5022 = 12 + 5010 5100 = 312 + 4788 5232 = 432 + 4800 5280 = 180 + 5100 5418 = 138 + 5280 5442 = 420 + 5022 5478 = 60 + 5418 5502 = 60 + 5442 5520 = 18 + 5502 5640 = 138 + 5502 5652 = 12 + 5640 5658 = 6 + 5652 5742 = 102 + 5640 5850 = 108 + 5742 5868 = 18 + 5850 5880 = 12 + 5868 6090 = 240 + 5850 6132 = 42 + 6090 6198 = 108 + 6090 6270 = 72 + 6198 6300 = 30 + 6270 6360 = 60 + 6300 6450 = 150 + 6300 6552 = 102 + 6450 6570 = 18 + 6552 6660 = 108 + 6552 6690 = 30 + 6660 6702 = 12 + 6690 6762 = 60 + 6702 6780 = 18 + 6762 6792 = 12 + 6780 6828 = 138 + 6690 6870 = 42 + 6828 6948 = 858 + 6090 6960 = 12 + 6948 7128 = 180 + 6948 7212 = 420 + 6792 7308 = 180 + 7128 7332 = 462 + 6870 7350 = 18 + 7332 7458 = 108 + 7350 7488 = 30 + 7458 7548 = 60 + 7488 7560 = 12 + 7548 7590 = 30 + 7560 7758 = 198 + 7560 7878 = 420 + 7458 7950 = 72 + 7878 8010 = 60 + 7950 8088 = 138 + 7950 8220 = 270 + 7950 8232 = 12 + 8220 8292 = 60 + 8232 8388 = 828 + 7560 8430 = 42 + 8388 8538 = 108 + 8430

8598 = 60 + 8538 8628 = 30 + 8598 8820 = 192 + 8628 8838 = 18 + 8820 8862 = 42 + 8820 8970 = 108 + 8862 9000 = 30 + 8970 9012 = 12 + 9000 9042 = 30 + 9012 9240 = 198 + 9042 9282 = 42 + 9240 9342 = 60 + 9282 9420 = 138 + 9282 9432 = 12 + 9420 9438 = 6 + 9432 9462 = 30 + 9432 9630 = 192 + 9438 9678 = 240 + 9438 9720 = 42 + 9678 9768 = 138 + 9630 9858 = 138 + 9720 9930 = 72 + 9858 How I would use this data is this. Don't try to prove this, but we can safely assume that given a complete list of twin primes $\leq x_n$ each in the list can be assumed to be the sum of two prior. I would, given such a list $X = x_0 \lt x_1 \lt \dots \lt x_n$, assume that for each $k = 1..n$ that the sublist $x_0 \lt \dots \lt x_k$ also has this summatory property. Perhaps from there we can form a contradiction if for each $x, y \in X$, we have that: $$ (x + y)^2 - 1 = 0 \pmod q, \\ \text{ for some prime } q \leq \sqrt{x + y + 1} $$ in a Sieve-of-Eratosthenese way. We must also then note that if $y = \max X$, then $\sqrt{2y + 1} \leq y - 2$ for sufficiently large y, namely $y \geq 6$. That means that the primes involved in showing that for at least one prime q we have $(x+y)^2 - 1= 0 \pmod q$ can be taken to be the same list Q by which each $x \in X$ is such that $x \pm 1 \neq 0 \pmod q$ for some $q \in Q$, i.e. namely all $q \leq y - 2$.

A question about 3-smooth differences between primes

There are an infinite number of primes p such that there are no prime $q<p$ such that $p-q$ is 2-smooth (a power of two) and the smallest such numbers are $p=2,127,149,...$. https://oeis.org/A065381. The same idea for 3-smooth differences yields the question if there are prime numbers $p>2$ such that it doesn't exists a prime $q<p$ such that $p-q$ is 3-smooth? Due to my tests such a prime is greater than 10^{10} if it exists. I do think there is such a failing prime but that my computation skills and computer systems are too limited to find out. Question: is there a failing prime or can it be proved that 3-smooth differences always exists? Comment shows there should be a lot of failing primes, but which is the smallest greater than 2? If $F=\{k\in\mathbb N_{>1} |2^{k-1}\equiv 1\pmod k\}$ one can ask for which $n\in F$ it doesn't exist a $m\in F,\; m<n$ such that $n-m$ is 3-smooth. For all $n\in \{t\in F | 10^{10}\leq t < 2\cdot10^{10}\}$ there exist one such number 19115108601, which is not a prime. A big gap from p downwards to previous prime should decrease the probabillity for 3-smooth gaps. I tested all so far known records of gaps Prime gaps Wikipedia without find an exception. So I add the conjecture tag. Below a diagram of the number of 3-smooth differences as a function of the prime p. The red curve is $\ln p$

Are there an infinity of consecutive primes that have no common digit?

Examples: 2 & 3, 3 & 5, 5 & 7, 59 & 61, 99999989 & 100000007. I was inspired by the fact that, in English, all consecutive numbers share a common letter, such as seven & eight that share 'e'. See Alex Bellos's Math Puzzle section https://www.theguardian.com/science/2023/feb/20/did-you-solve-it-thats-mathematics. Instead I consider consecutive primes and their base representation. Except for 2 & 3, 3 & 5 and 5 & 7 all such base-10 consecutive primes are of the form: $a \times 10^n - b$ and $a \times 10^n + c$ with $1 \le a\le 8$. It is easy to show that a cannot be 9. I found 701 cases below 10^{500}. A large example is $1 \times 10^{101}-203\ \ $ & $\ \ 1 \times 10^{101}+3$ and a larger example (with probable primes) is $8 \times 10^{5002}-6243\ \ $ & $\ \ 8 \times 10^{5002}+14481$. I am pessimistic that the conjecture can be easily proved. Landau's conjecture that there are infinitely many primes p of the form $p=n^2+1$ remains open. For other bases: in base 2 there are no such consecutive primes. In base 3 it is easy to show that there are none, except 2 & 3. Base 4 is the first interesting base. All cases must be of the form $4^n - b$ and $4^n + c$ (except for 2 & 3). I found only 5 cases with n = 1, 4, 28, 83 and 1816. EDIT: Replaced "disjoint" with the more standard "have no common digits". See the result for squares in oeis.org/A156981

A graph where for each pair of vertices, there exist a vértice adjacent to both and a vértice adjacent to neither

Can we construct a simple $G=(V, E) $ so that for any pair $u, v\in V $, there is a vértix x adjacent to both, as well as a vertix y that is not adjacent to either u, v. So, $ux, vx \in E$ and $uy, vy\notin E $. I believe this to be impossible, and therefore conjecture that if every pair of people have a mutual friend, then one pair doesn't have a mutual stranger. Can someone find a counterexample?

Every bipartite graph is an induced subgraph of a hypercube graph?

UPDATE: THIS IS FALSE. I came up with this question some day and have been working on it for some time: Every bipartite graph G is an induced subgraph of a hypercube graph Q_n. Here the hypercube graph is a graph defined as follows: The hypercube graph $Q_n(V_n,E_n)$ with $V_n=\{\text{all subsets of }\{1, 2, ... , n\}\}$, $E_n=\{\{u,v\}:|u\triangle v|=1\}$, where $A\triangle B=(A\setminus B)\cup(B\setminus A)$. With some small examples I believe this is correct. Here's what I've trying to do: by block decomposition we reduce to the biconnected scenario. Every biconnected graph can be constructed as follows: starting from a cycle, and adding paths to the graph. If we can present a way to add the paths in such a way that the add path itself is longer than the original distance of the two ends (in the graph before adding this path), we can always label a subset of $\mathbb{Z}_+$ on every vertices added such that two vertices are incident if and

only if the subset labelled on them has the difference of exactly one element (i.e. $|A\triangle B|=1$), because every cycle is even. (This should be true, I think) In this way we can embed this graph to some Q_n. Now it remains to show the "if" is true. I tried to add the shortest path every time but this doesn't seem to work.

Conjectures with the strongest numerical evidence later proven to be false

For a number of conjectures in number theory, the truth of some statement has been checked up to extremely large values. E.g. There are no odd perfect numbers below 10^{1500} Are there any examples where a conjecture eas believed to be true, and also had huge empirical evidence that it should be true, but was later proven to be false?

Strengthening of FLT

FLT is that there are no positive nontrivial integer solutions to the Diophantine equation $a^n + b^n = c^n$ for $n>2$. What about the conjecture that there are no nontrivial solutions to the DE $a^n + b^n = c^n + d^n$ for $n>4$; is there an explicit name for it? I know that it’s a case of Lander, Parkin, Selfridge, but does this particular case have its own name? It’s so natural that it must have its own name, one would figure.

Friendship theorem for bipartite graphs

The friendship theorem states that if every pair of people has exactly one common friend, then one person is friends with everybody. Which is unfortunately not easy to actually proof. I came up with the following variation on this theorem regarding bipartite graphs: if every pair of females has exactly one mutual male friend, and every pair of males has exactly one mutual female friend (the bipartite friendship condition), but the amount of females and males are not equal, then one male is friends with every girl and one girl is friends with every boy. If the amount of females and males are equal and more than 3, then there is another possible configuration: there is a popular male and popular female, who are friends with everyone from the other gender , except with each other. Everyone else has exactly 2 friends of opposite gender. Can we prove that these are the only bipartite graphs satisfying the bipartite friendship condition?

Formula for the ratio of Numbers not divisible by the first n primes

I was playing around with prime numbers, and specifically how many numbers we can exclude from an interval from being primes. It is easy to see, that after 2, the ratio of numbers is $1-\frac{1}{2}$, as we know every second number to be divisible by 2 and, as such be impossible to be a prime. After we include 3, the ratio would be $1-\frac{1}{2}-\frac{1}{3}$, except that every number divisible by 6 would be excluded once by the $\frac{1}{2}$ and a second time by the $\frac{1}{3}$. Therefore in the actual ratio we have to add every sixth number again. So the actual ratio is $1-\frac{1}{2}-\frac{1}{3}+\frac{1}{6}$. And naturally I wondered how this sequence continues once we include 5. However, the number of terms grows rapidly. This is because 1: We have to add back every tenth and fiveteenth number, again, as we would otherwise subtract them twice by the $\frac{1}{2}$ and $\frac{1}{5}$ or the $\frac{1}{3}$ and $\frac{1}{5}$ respectively. 2: We have to subtract every 30eth Number, as we subtract them thrice from the $2,3,5$ and add them back thrice from the $6,10,15$, so as to not ignore these, we subtract them. This is the sequence I have arrived at, although I could be missing something $1-\frac{1}{2}-\frac{1}{3}+\frac{1}{6}-\frac{1}{5}+\frac{1}{10}+\frac{1}{15}-\frac{1}{30}$ Conjectured sequence If we look at the number of terms, the sequence $1,2,4,8$ appears, furthermore, if we look at the latter half of our sequence for the first 3 prime numbers $(-\frac{1}{5}+\frac{1}{10}+\frac{1}{15}-\frac{1}{30})$, it is just the first half $(1-\frac{1}{2}-\frac{1}{3}+\frac{1}{6})$ multiplied by $-\frac{1}{5}$. So here is my conjecture stated a bit more mathematically: Let p_n be the n-th prime number, $r(n)$ the ratio of natural numbers divisible by the first n prime numbers to the natural numbers, then \begin{multline} r(0)=1,\\ r(n+1)=r(n)-\frac{1}{p_{n+1}}r(n)\\ =r(n)\cdot\left(1-\frac{1}{p_{n+1}}\right)\\ =r(0)\cdot\left(1-\frac{1}{p_1}\right)\left(1-\frac{1}{p_2}\right)...\left(1-\frac{1}{p_{n+1}}\right)\\ =\prod_{i=1}^{n+1}\left(1-\frac{1}{p_i}\right) \end{multline} My question is: is this true? It seems true but again, as the number of terms grow so rapidly I could have missed

something. I am also very certain, that I was not the first to have this idea, but I failed to find any theorem like this on google.

Conjecture about the minimum of the Gamma function

Problem/Conjecture: Let the function : $$f(x)=\frac{((x+x_{\min})!-(x_{\min})!)^{\frac{1}{x}}}{x^{\frac{1}{x^2}}}$$ Where $x_\min$ denotes the minimum abscissa of the Gamma function near by 0.4616 Then do we have : $$f'(1-x_{\min})<^?0$$ An computation show it could be true. And what is : $$\lim_{x\to \infty}(f(x)-f(x-1))=?$$ Is it true? If yes is it trivial or well-know ?

Conjecture: Shallow diagonals in Pascal's triangle form polynomials whose roots are all real, distinct, and in $(-2,2)$.

Here are the first few "shallow diagonals" in Pascal's triangle. We can use these shallow diagonals to make polynomials. Note that the even degree polynomials have an extra $\pm x$ at the end. x x^2-x x^3-x x^4-2x^2+x x^5-3x^3+x $x^6-4x^4+3x^2-x$ $x^7-5x^5+6x^3-x$ $x^8-6x^6+10x^4-4x^2+x$ $\dots$ Here is an explicit description (you can skip this part if you already see the pattern): In the nth row of Pascal's triangle (first row is $n=1$), let the leftmost number be the leftmost number of a shallow diagonal. If n is odd, say $2k-1$, call the numbers in this shallow diagonal, from left to right, $a_1, a_3, \dots, a_{2k-1}$, and let $P_{2k-1}(x)=\sum\limits_{i=1}^{k} (-1)^{i-1}a_{2i-1}x^{2(k-i)+1}$. If n is even, say $2k$, call the numbers in this shallow diagonal, from left to right, $a_2, a_4, \dots, a_{2k}$, and let $P_{2k}(x)=\sum\limits_{i=1}^{k} (-1)^{i-1}a_{2i}x^{2(k+1-i)}+(-1)^{k}x$. Conjecture: For each of these polynomials, all of the roots are real, distinct, and in $(-2,2)$. Is my conjecture true? I've been picking random shallow diagonals, and so far I have not found a counter-example. Here are more shallow diagonals, and more even numbered shallow diagonals. Context: I formulated this conjecture when trying to answer another question of mine: For given n, how to find integers $a_0, ..., a_n$ so that $\sum_{k=0}^n a_k x^k$ has n distinct real roots and $\sum_{k=0}^n |a_k|$ is minimized?

Possible connection between binary numbers and π

Here is the Desmos if you want to follow along: https://www.desmos.com/calculator/b4vtzruupm In messing around with binary numbers, I created a function $f(x)$ in Desmos that generated a list of digits of the binary representation of the input x in reverse. For example, $f(10)$ would output $[0,1,0,1]$. I then created a function $g(z)$ that created a list of points $(z,\text{indexes of all 1s in f(z)}))$. For example, $g(10)$ would output $(10,2),(10,4)$. $(10,1)$ and $(10,3)$ were removed because the first and third numbers in $f(10)$ were 0. Then, I created a list h made up of lists of $g(x)$ where $x\in\mathbb{N}$. After testing a few lists of natural numbers for x. I created a python program that let me put a little more than a thousand values of x in $g(x)$ without having to manually type them in. I then did a regression $h.y=\log_n(h.x)$ where $h.x$ denotes the list of x-values in h and $h.y$ denotes the list of y-values in h. After doing thorough testing with lists such as $[1,...,1000]$ and $[1000,...,1600]$, it seemed like as if I were to use the set of all natural numbers, the value of n from the regression would be equal to π. For example, the range $[600,...,1500]$ gave me $n=3.1562889032$. I used many other ranges too. Conjecture: Pick a positive integer N, and construct a set S of tuples consisting of all pairs $(\log m,i)$ for which $1\le m\le N$ and m has a one in the 2^{i-1}'s place when written in binary. Find the line through the origin of best fit for the points S. Then the slope, as $N\to\infty$, tends to $\log\pi$. It would be much appreciated if anyone could help prove, disprove, and/or explain this. I would also really appreciate if someone helped me edit my post to make it clearer and easier to understand as I struggled with trying to explain what I was doing at points and think it is a little confusing. Thanks in advance.

Equivalent definition of convergence of a sequence in $\mathbb{R}$

While reading over the definition of a Cauchy sequence in $\mathbb{R}$, I conjectured that the following condition $\forall \epsilon>0, \exists N\in\mathbb{N}: \forall n>N, |a_n-a_N|<\epsilon$ is necessary and sufficient for a sequence in $\mathbb{R}$ to converge. Is this true? I haven't been able to find any counterexamples or proofs of this conjecture on this site. If this is indeed true, I'm guessing that a proof would involve subsequences and/or the Cauchy sequence condition.

Differences between primes which are powers of two

Not for every prime p there is smaller prime q such that $p-q=2^n$ for some natural number n and $n=127$ is an example. But what about the dual question: For each prime number $p>2$ there is a natural number n such that $p+2^n$ is a prime number. What is known about this?

Does an odd perfect number have a divisor (other than 1) which must necessarily be almost perfect?

Let $\sigma(x)=\sigma_1(x)$ be the classical sum of divisors of the positive integer x. Denote the aliquot sum of x by $s(x)=\sigma(x)-x$ and the deficiency of x by $d(x)=2x-\sigma(x)$. Finally, denote the abundancy index of x by $I(x)=\sigma(x)/x$. A number P is said to be perfect if $\sigma(P)=2P$. On the other hand, if a number A satisfies $\sigma(A)=2A-1$, then A is said to be almost perfect. (The only known examples for A are the powers of two, including 1.) Lastly, a number D is said to be deficient-perfect if the deficiency $d(D)$ of D divides D. Even Perfect Numbers The three smallest examples for P are $$6=2\cdot{3}={2^1}\cdot\left(2^2 - 1\right)$$ $$28=4\cdot{7}={2^2}\cdot\left(2^3 - 1\right)$$ $$496={16}\cdot{31}={2^4}\cdot\left(2^5 - 1\right).$$ The Euclid-Euler Theorem states that an even number E is perfect if and only if E has the form $$E={2^{p-1}}\cdot\left(2^p - 1\right) = \frac{M_p (M_p + 1)}{2},$$ where $M_p = 2^p - 1$ is a Mersenne prime. (Note that if M_p is prime, then p is also prime. The converse does not necessarily hold.) Only 51 Mersenne primes are known, corresponding to an equal number of (even) perfect numbers. (See this GIMPS page.) It is currently unknown whether there are finitely many such numbers E. It has been conjectured that there are infinitely many even perfect numbers. Note that we have the equations $$1=\gcd\left(M_p,\frac{M_p + 1}{2}\right)=\sigma\left(\frac{M_p + 1}{2}\right)/M_p=\frac{M_p + 1}{\sigma(M_p)}=\frac{d\left(\frac{M_p + 1}{2}\right)}{s(M_p)}=\frac{2s\left(\frac{M_p + 1}{2}\right)}{d(M_p)}$$ so that $$d\left(\frac{M_p + 1}{2}\right)d(M_p)=2s\left(\frac{M_p + 1}{2}\right)s(M_p).$$ (Note that, trivially, we have $(M_p + 1)/2 < M_p$.) Odd Perfect Numbers Much less is known about odd perfect numbers O. We do not know an actual value for even just a single divisor of O, apart from the trivial factor 1. This is because we do not have an example for O, unlike the case for E. (In a letter to Mersenne dated November 15, 1638, Descartes showed that $$\mathscr{D} = {{3}^2}\cdot{{7}^2}\cdot{{11}^2}\cdot{{13}^2}\cdot{22021} = 198585576189$$ would be an odd perfect number if 22021 were prime.) Nonetheless, Euler did prove that O must necessarily have the so-called Eulerian form $$O = q^k n^2$$ where q is the special prime satisfying $q \equiv k \equiv 1 \pmod 4$ and $\gcd(q,n)=1$. Note that we have the equations $$1 < \gcd(n^2,\sigma(n^2))=\frac{\sigma(n^2)}{q^k}=\frac{2n^2}{\sigma(q^k)}=\frac{d(n^2)}{s(q^k)}=\frac{2s(n^2)}{d(q^k)} \tag{*}$$ so that $$d(q^k)d(n^2)=2s(q^k)s(n^2).$$ (It is known that $q^k < n^2$.) Odd Perfect Numbers Must Have a Deficient-Perfect Divisor Remark 1. We may define a deficient-perfect number D to be a positive integer having a proper divisor e satisfying $$\sigma(D) = 2D - e.$$ The divisor e is said to be the deficient divisor of D. Remark 2. It is also easy to show that the deficient divisor e of a deficient-perfect number D is the greatest common divisor of D and $\sigma(D)$. That is, we have $$e=\gcd(D,\sigma(D))$$ if $σ(D) = 2D - e$ and $e \mid D$, $e \neq D$. Holdener and Rachfal (2019) proved the following assertion: THEOREM 1. Every odd perfect number has a deficient-perfect divisor. In particular, if $O = q^k n^2$ is an odd perfect number given in Eulerian form, then the divisor $D_O = q^j n^2$ is deficient-perfect, with deficient divisor $$e_O=\frac{2q^j n^2}{q^{j+1} + 1},$$ where $j=(k-1)/2$. In particular, by Remark 1 and Remark 2, we obtain $$\gcd\left(D_O,\sigma(D_O)\right)=e_O=2D_O-\sigma(D_O)=d(D_O).$$ Following in the footsteps of this short ResearchGate article, titled "Gcd in Odd perfect number" by Devansh Singh (B.Tech, M.E., I.E.T. Lucknow), we proceed as follows: From the Eulerian form $O=q^k n^2$, we get $$O={q^{(k+1)/2}}\cdot\left(q^{(k-1)/2} n^2\right)={q^{(k+1)/2}}\cdot{D_O}.$$ Since $\gcd\left(q^{(k+1)/2},q^{(k-1)/2} n^2\right)=1$ if and only if $k=1$, then we are unable to tie up, in full generality, the value of $$\sigma(O/q^k)/q^{j+1}=\sigma(n^2)/q^{(k+1)/2}$$ with that of $$\gcd(D_O,\sigma(D_O))=\gcd\left(q^{(k-1)/2} n^2,\sigma(q^{(k-1)/2} n^2)\right),$$ by using Singh's approach. This is getting too long already, so let me ask my question (as is) in the title: QUESTION. Does an odd perfect number have a divisor (other than 1) which must necessarily be almost perfect? MY ATTEMPT Note from the definitions that, if a number is almost perfect, then it is automatically deficient-perfect. Suppose to the contrary that the deficiency $d(D_O)$ of the deficient-perfect divisor $D_O=q^j n^2$ of an odd perfect number $O=q^k n^2$ satisfies $d(D_O)=1$ (where $j=(k-1)/2$). (Notice that D_O is a square.) In other words, assume that D_O is almost perfect. Then we have, by a criterion in this paper, the following inequality $$\frac{2D_O}{D_O + 1}< I(D_O) < \frac{2D_O + 1}{D_O + 1}$$ since $D_O > 1$ and D_O is almost perfect. Using the fact that the abundancy index function I is multiplicative, we obtain $$I(D_O)=I(q^j n^2)=I(q^j)I(n^2).$$ If $k=1$, then using the equations and inequality in $(*)$, we obtain $$1<\gcd(n^2,\sigma(n^2))=d(n^2),$$ which contradicts our earlier assumption that $d(D_O)=1$. Thus, it suffices to consider $k \neq 1$. Since $k \equiv 1 \pmod 4$ holds, then $k \geq 5$. It follows that $j=(k-1)/2 \geq 2$. In particular, we have $$I\left((qn)^2\right) = I(q^2)I(n^2) \leq I(D_O) < \frac{2q^j n^2 + 1}{q^j n^2 + 1} \tag{1}$$ and $$\frac{2q^j n^2}{q^j n^2 + 1} < I(D_O) = I(q^j)I(n^2) = \left(\frac{q^{j+1} - 1}{q^j (q - 1)}\right)\cdot{I(n^2)} < \left(\frac{q}{q - 1}\right)\cdot\left(\frac{2q}{q + 1}\right) = \frac{2q^2}{q^2 - 1}. \tag{2}$$ Inequality (2) results to $$0 < 2\left(q^j n^2 + q^2\right)$$ which is trivial. On the other hand, we derive the following estimate from Inequality (1): $$I(q^2)I(n^2)=\left(\frac{\sigma(q^2)}{q^2}\right)\cdot{I(n^2)}=\left(\frac{q^2 + q + 1}{q^2}\right)\cdot{I(n^2)}$$ $$>\left(\frac{q^2 + q + 1}{q^2}\right)\cdot\left(\frac{2(q-1)}{q} + \frac{1}{qn^2}\right).$$ We now test whether the inequality $$\left(\frac{q^2 + q + 1}{q^2}\right)\cdot\left(\frac{2(q-1)}{q} + \frac{1}{qn^2}\right) < \frac{2q^j n^2 + 1}{q^j n^2 + 1} \tag{3}$$ indeed holds. Using some help from WolframAlpha, Inequality (3) holds when $q < n$. To conclude, $D_O = q^j n^2$ might be an almost perfect divisor of the odd perfect number $O=q^k n^2$, where $j=(k-1)/2$, as we were not able to derive a contradiction from assuming that D_O is indeed almost perfect, and then using our criterion for almost perfect numbers. I will stop here for the time being, as I have got some more work to do.

The Connell Sequence and the Number of Ones in Redheffer Matrices

The divisor matrix $D=(d_{r,s})_{r,s\in\mathbf{N}}$ is defined by $d_{r,s}=1$ if r divides s and 0 otherwise. Raymond Redheffer considered a finite truncation of the divisor matrix. For each natural number n he considered the matrix, denoted R_{n}, obtained from the upper left $n\times n$ submatrix of D by setting each entry in the first column equal to 1. I say R_{n} is even if its number of nonzero entries is even, otherwise I say it is odd. Consider the following table: \begin{array}{ l | l | l } n & \text{No. of nonzero entries of R_{n}} & \text{parity of R_{n}} \\ \hline 1 & 1 & \text{odd} \\ 2 & 4 & \text{even} \\ 3 & 7 & \text{odd} \\ 4 & 11 & \text{odd} \\ 5 & 14 & \text{even} \\ 6 & 19 & \text{odd} \\ 7 & 22 & \text{even} \\ 8 & 27 & \text{odd} \\ 9 & 31 & \text{odd} \\ 10 & 36 & \text{even} \\ 11 & 39 & \text{odd} \\ 12 & 46 & \text{even} \\ 13 & 49 & \text{odd} \\ 14 & 54 & \text{even} \\ 15 & 59 & \text{odd} \\ \end{array} The values n for which the matrices R_{n}, are even in parity are the numbers $2,5,7,10,12,14,\ldots$ Similarly the values n for which the matrices R_{n} are odd in parity are the numbers $1,3,4,6,8,9,11,13,15,\ldots$ Writing in 1959 to the journal American Mathematical Monthly Ian Connell challenged readers to find a closed form to an unusual sequence. The sequence, which now bears his name, is made as follows: begin by writing the first odd number, 1, then write the next two even numbers after 1: $2, 4$ and then write the next three odd numbers after 4: $5, 7, 9$ and then write the next four even numbers after 9: $10, 12, 14, 16$, and so on. The first few terms are $1, 2, 4, 5, 7, 9, 10, 12, 14, 16, 17,\ldots$ A solution to Connell's challenge appeared in the same journal in 1960, where it was shown the n-th term of the Connell sequence, a_{n}, has the closed form $2n - \lfloor1/2(1 + \sqrt{8n - 7})\rfloor$. The sequences is found in the Online Encyclopedia of Integer Sequences (OEIS) by looking up the entry A001614. A modification to the Connell Sequence can be made by replacing the first term of the Connell sequence with the even number 0 and then proceed by writing down runs of n consecutive numbers of a given parity. In particular begin by writing the first even number 0, then write the next two odd numbers after 0: $1, 3$ then write the next three even numbers after 3: $4, 6 ,8$ and write the next four odd numbers after 8: $9,11,13, 15$, and so on. The first few terms are $0,1,3,4,6,8,9,11,13,15,\ldots$ The modified Connell sequence is found in the OEIS by looking up the entry A133280. There one finds a closed formula for the n-th term, a_{n}, namely $1+2n-\lfloor 1/2+\sqrt{2n + 2}\rfloor$. I say a number is a Connell number if it belongs to the Connell sequence. I say a number is a modified Connell number if it belongs to the modified Connell sequence. The Connell sequence and their modifications span the natural numbers and share the perfect squares between them. It is straightforward to show that the average order of the Connell numbers and their modification is $2,$ that is $\lim_{n\to\infty}a_{n}/n=2.$ Here is the Question: Are the following items true? R_{n} is even if and only if n is a Connell number that is not a perfect square. R_{n} is odd if and only if n is a modified Connell number. For example $n=19$ is a Connell number that is not a perfect square, and so we should expect R_{19} to have an even number on nonzero entries. Indeed, the number of nonzero entries in R_{19} is 78. Similarly, if $n=36$, a modified Connell number then we should expect R_{36} to have an odd number of nonzero entries. Sure enough, R_{36} has 175 nonzero entries.

Conjecture about expected distance between two points in a regular polygon

Point P is a uniformly random point on the perimeter of a regular polygon. Point C is a fixed point somewhere on the circle inscribed in the polygon. Is the following conjecture true: The expected distance between C and P is maximized when C is where the circle touches the polygon. Numerical investigation shows that the conjecture is true for a square. Suppose the square has vertices $(\pm1,\pm1)$. C has coordinates $(\cos\theta, \sin\theta)$. $E(PC)=\frac18\left(\int_{-1}^1 \sqrt{(\cos\theta-x)^2+(\sin\theta+1)^2}dx+\int_{-1}^1 \sqrt{(\cos\theta-1)^2+(\sin\theta-y)^2}dy+\int_{-1}^1 \sqrt{(\cos\theta-x)^2+(\sin\theta-1)^2}dx+\int_{-1}^1 \sqrt{(\cos\theta+1)^2+(\sin\theta-y)^2}dy\right)$ Here is the graph of $E(PC)$ against θ for $0\le \theta \le \pi/2$. The graph shows that $E(PC)$ is maximized when $\theta=0$, i.e. when C is where the circle touches the square. Is my conjecture true for all regular polygons?

Reference Request - Online copy of R. Graham's "On Finite Sums of Rational Numbers"

Does anyone know where I could find a copy of Ron Graham's PhD dissertation, titled "On Finite Sums of Rational Numbers"? I found this paper, with a similar title, but I could not find Professor Graham's dissertation. I need to double-check some detail(s) in Professor Graham's dissertation which may not be in the published version. This is in consideration of my (current) approach to odd perfect numbers via Egyptian fractions.

Who discovered the largest known 3-perfect number in 1643?

Multiperfect numbers probably need no introduction. (These numbers are defined in Wikipedia and MathWorld.) I need the answer to the following question as additional context for a research article that I am currently writing: Who discovered (in the year 1643) the largest known 3-perfect number to date? Here are the six known 3-perfect numbers, with the last being discovered more than 360 years ago, in 1643: \begin{align*} 120 &= 2^3 \times 3 \times 5, \\ 672 &= 2^5 \times 3 \times 7, \\ 523776 &= 2^9 \times 3 \times 11 \times 31, \\ 459818240 &= 2^8 \times 5 \times 7 \times 19 \times 37 \times 73, \\ 1476304896 &= 2^{13} \times 3 \times 11 \times 43 \times 127, \\ 51001180160 &= 2^{14} \times 5 \times 7 \times 19 \times 31 \times 151. \\ \end{align*} Note that N is an odd perfect number if and only if $2N$ is a (necessarily) even 3-perfect number. (My profuse thanks to Professor V. M. Misyakov for pointing out my mistake in ResearchGate.)

This link asserts that it was René Descartes who discovered the following multiperfect numbers: \begin{array}{|c|c|c|c|} \hline \text{index} &\text{smallest} &\text{name} & \text{ found by } \\ \hline 4 &30240 &4-\text{perfect} &\text{Descartes (1638)} \\ \hline 5 & 14182439040 & 5-\text{perfect} &\text{Descartes (1638)} \\ \hline \end{array} Perhaps \begin{align*} 51001180160 &= 2^{14} \times 5 \times 7 \times 19 \times 31 \times 151 \end{align*} was also discovered by Descartes in 1643, judging from the timing. Did he?

When is $\frac{5^n - 1}{4}$ squarefree?

While researching the topic of odd perfect numbers, I came across the following related subproblem: PROBLEM: Determine congruence conditions (on $n > 1$) such that $$\frac{5^n - 1}{4}$$ is squarefree. MY ATTEMPT Set $$m_n := \frac{5^n - 1}{4}.$$ I noticed that $m = m_1 = 1$ is squarefree for $n = 1$. Next, I considered the prime factorizations of m_n for the first fifteen values (i.e., $2 \leq n \leq 16$): $$\begin{array}{|c|c|c|} \hline \text{Value of } n &\text{Value of } m_n & \text{Prime Factorization of } m_n \\ \hline 2 & 6 & 2 \times 3 \\ \hline 3 & 31 & 31 \\ \hline 4 & 156 & {2}^2 \times 3 \times 13 \\ \hline 5 & 781 & 11 \times 71 \\ \hline 6 & 3906 & 2 \times {3}^2 \times 7 \times 31 \\ \hline 7 & 19531 & 19531 \\ \hline 8 & 97656 & {2^3} \times 3 \times 13 \times 313 \\ \hline 9 & 488281 & 19 \times 31 \times 829 \\ \hline 10 & 2441406 & 2 \times 3 \times 11 \times 71 \times 521 \\ \hline 11 & 12207031 & 12207031 \\ \hline 12 & 61035156 & 2^2 \times 3^2 \times 7 \times 13 \times 31 \times 601 \\ \hline 13 & 305175781 & 305175781 \\ \hline 14 & 1525878906 & 2 \times 3 \times 29 \times 449 \times 19531 \\ \hline 15 & 7629394531 & 11 \times 31 \times 71 \times 181 \times 1741 \\ \hline 16 & 38146972656 & 2^4 \times 3 \times 13 \times 17 \times 313 \times 11489 \\ \hline \end{array}$$ From this initial data sample, I predict the truth of the following conjectures: CONJECTURE 1: If $n \equiv 0 \pmod 6$, then m_n is not squarefree. CONJECTURE 2: If $n \equiv 0 \pmod 5$, then m_n is squarefree. CONJECTURE 3: If $n \equiv 0 \pmod 3$ and n is odd, then m_n is squarefree. OBSERVATION - If m_n is a prime number, then n must also prime. I skimmed through OEIS sequence A005117 and did not find any references to these conjectures. ATTEMPTING TO RESOLVE CONJECTURE 1 I searched for counterexamples to Conjecture 1 using Pari-GP in Sage Cell Server, I did not get any output in the range $2 \leq n \leq 100$: This gives further computational evidence for Conjecture 1. RESOLVING CONJECTURE 2 I searched for counterexamples to Conjecture 2 using Pari-GP in Sage Cell Server, I got the following output in the range $2 \leq n \leq 100$: 20[2, 2; 3, 1; 11, 1; 13, 1; 41, 1; 71, 1; 521, 1; 9161, 1] 30[2, 1; 3, 2; 7, 1; 11, 1; 31, 1; 61, 1; 71, 1; 181, 1; 521, 1; 1741, 1; 7621, 1] 40[2, 3; 3, 1; 11, 1; 13, 1; 41, 1; 71, 1; 241, 1; 313, 1; 521, 1; 9161, 1; 632133361, 1] 55[11, 2; 71, 1; 103511, 1; 511831, 1; 12207031, 1; 65628751, 1; 190295821, 1] 60[2, 2; 3, 2; 7, 1; 11, 1; 13, 1; 31, 1; 41, 1; 61, 1; 71, 1; 181, 1; 521, 1; 601, 1; 1741, 1; 2281, 1; 7621, 1; 9161, 1; 69566521, 1] 80[2, 4; 3, 1; 11, 1; 13, 1; 17, 1; 41, 1; 71, 1; 241, 1; 313, 1; 521, 1; 9161, 1; 11489, 1; 25601, 1; 632133361, 1; 9094568478143344O1, 1] 90[2, 1; 3, 3; 7, 1; 11, 1; 19, 1; 31, 1; 61, 1; 71, 1; 181, 1; 521, 1; 829, 1; 1171, 1; 1741, 1; 5167, 1; 7621, 1; 169831, 1; 297315901, 1; 60081451169922001, 1] 100[2, 2; 3, 1; 11, 1; 13, 1; 41, 1; 71, 1; 101, 1; 251, 1; 401, 1; 521, 1; 1901, 1; 9161, 1; 239201, 1; 9384251, 1; 424256201, 1; 50150933101, 1; 89620825374601, 1] This means that Conjecture 2 is false. RESOLVING CONJECTURE 3 I searched for counterexamples to Conjecture 3 using Pari-GP in Sage Cell Server, I got the following output in the range $2 \leq n \leq 100$: 93[31, 2; 1861, 1; 148429, 1; 878851, 1; 625552508473588471, 1; 1729748124632393100247504109291, 1] This means that Conjecture 3 is false. RESOLVING AN OBSERVATION I searched for counterexamples to Conjecture 4 using Pari-GP in Sage Cell Server, I did not get any output in the range $2 \leq n \leq 888$. I did search for the primes n satisfying Conjecture 4, in the range $2 \leq n \leq 888$, here is the output: 3Mat([31, 1]) 7Mat([19531, 1]) 11Mat([12207031, 1]) 13Mat([305175781, 1]) 47Mat([17763568394002504646778106689453l, 1]) 127Mat([14693679385278593849609206715278070972733319459651094018859396328480215743184089660644531, 1]) 149Mat([35032461608120426773093239582247903282006548546912894293926707097244777067146515037165954709053039550781, 1]) 181Mat([81566305849981556583878676365706844446264553225862081846982955693371540557468577840286201585673353520178352482616901397705078l, 1]) 619Mat([11491393399729176129058599637568039590983414433049669131423473249238986267377190768602760303952289003868743764537870943345358977246251614482432860160834726163018294937275891867524154115188155135131886536077893354390566834817748709990440493780386105420979057745074407793143691403688802000506454789703520782599348592727930257167323682704508334081537013209268294956642082599042229570588087445297438560221081615964067168538020324707031, 1]) This means that the numbers $$\frac{5^3 - 1}{4}, \frac{5^7 - 1}{4}, \frac{5^{11} - 1}{4}, \frac{5^{13} - 1}{4},$$ $$\frac{5^{47} - 1}{4}, \frac{5^{127} - 1}{4}, \frac{5^{149} - 1}{4}, \frac{5^{181} - 1}{4}, \frac{5^{619} - 1}{4}$$ are all prime. We end this section with the following prediction: CONJECTURE 4: The divisibility condition $n \mid m_n$ holds when either (a) $5 \nmid n$; or (b) n is an odd prime. Alas, this where I get stuck, as I do not currently know how to prove Conjectures 1 and 4.

Conjecture improvement of Bunyakovsky integral inequality $\int_{0}^{I}g(t)dt\leq J$

It's a follow-up of my previous question answered by user Apass.Jack nicely. See this post for motivation and background. Conjecture : Let f be a positive increasing continuous function on $x\in[0,1]$ and g be an integrable decreasing positive continuous function on $x\in(0,\infty)$. Let $$J=\left(\int_{0}^{1}\left(f\left(x\right)\right)^{2}dx\int_{0}^{1}\left(g\left(x\right)\right)^{2}dx-\left(\int_{0}^{1}f\left(x\right)g\left(x\right)dx\right)^{2}\right)\max_{x\in\left[0,1\right]}\left(g\left(x\right)\right)$$ and $$I=\left(\int_{0}^{1}\left(f\left(x\right)\right)^{2}dx\int_{0}^{1}\left(g\left(x\right)\right)^{2}dx-\left(\int_{0}^{1}f\left(x\right)g\left(x\right)dx\right)^{2}\right).$$ Then $$\left(\int_{0}^{I}g\left(t\right)dt\right)\leq J.$$ Now the usual counterexample doesn't works @Apass.jack. Here is one example : Choosing $g(x)=\arccos(x),f(x)=\arcsin(x)$ we have : $$2\frac{\left(1/4(2(2+((1+\pi)(4-(\pi-3)\pi^{2}))^{\frac{1}{2}})+\pi((\pi-3)\pi\arccos(1/4(\pi-3)\pi^{2})-((1+\pi)(4-(\pi-3)\pi^{2}))^{\frac{1}{2}}))\right)}{\pi}< \left(\frac{1}{4}\left(\pi^{2}-8\right)\left(\pi-2\right)-\left(2-\frac{\pi}{2}\right)^{2}\right)$$ $$I=\int_{0}^{1}e^{-x^{2}}dx\int_{0}^{1}\left(1+\frac

{1}{2}e^{-x}\right)dx-\left(\int_{0}^{1}\sqrt{e^{-x^{2}}\left(1+\frac{1}{2}e^{-x}\right)}dx\right)^{2},$$ $$\left|\int_{0}^{I}e^{-t^{2}}dt-I\right|<6\cdot10^{-7}$$ As I have no idea for a proof, here is my question. How to (dis)prove my conjecture?

Conjecture: Every shear transformation of the plane is congruent to a dilation

I conjecture that every shear transformation of the plane is geometrically congruent to an orthogonal dilation of the plane. That is, in Euclidean geometry of the plane, if I shear figure F, I can produce a geometrically congruent figure F' via orthogonal dilation. Is my conjecture correct? If so, what is the orthogonal dilation D congruent to $$\begin{bmatrix}1 & \tan \theta \\ 0 & 1\end{bmatrix}.$$ Since shears have determinant 1, I believe it must be of the form $$\begin{bmatrix}\alpha & 0 \\ 0 & \frac 1 \alpha \end{bmatrix},$$ but can't figure out α as a function of θ (or of λ in the general case above). Likewise, consider - what dilation, along any axes, can produce it? I haven't been able to sketch one. The support for this conjecture is via linear algebra; below are the definitions and support: Definitions Shear transformation means $S: \mathbb R^2 \to \mathbb R^2, S = \begin{bmatrix}1 & \lambda \\ 0 & 1\end{bmatrix}$ or $S = \begin{bmatrix}1 & 0 \\ \lambda & 1\end{bmatrix}$. Congruent is defined: a set of points F is congruent to F' if there is an isometry (preserving distance, angles, and colinearity) that sends $F \to F'$. Note that congruent does not imply matrix similarity: it a geometric property related by isometry. Orthogonal dilation means an arbitrary set of axes is chosen, each orthogonal to the rest, and the plane is scaled by a (perhaps different) constant along each. This is precisely the matrices of the form PDP^{-1} where P is orthogonal and D is diagonal. Conjecture I conjecture that for any shear S there exists an orthogonal dilation D such that for all figures F, $S(F) \cong D(F)$. Support Every real 2x2 matrix can be decomposed into a polar decomposition $A = PU$ where U is orthogonal diagonizable and P is an orthogonal matrix (and therefore an isometry). This implies the conjecture and also something related: Every dilation along non-orthogonal axes is congruent to a dilation along congruent axes. Background: While trying to determine Geometrically, what is unique about the mapping of an orthogonally diagonizable matrix (versus non-orthogonal)? , I came to the conclusion that there is no difference: every diagonalizable transform is geometrically congruent to an orthogonally diagonalizable geometric transform! Further background to this conjecture is at Is every symmetric matrix in $\mathbb R^n$ a (non-uniform) stretch? .

Conjecture: It is not true that 2 eventually always divides $f(x) = \sum_{d \mid p_{\sqrt{x+1}}\#} (d \mid x^2 - 1)$.

Lemma. Let $(d \mid \cdot) : \Bbb{Z} \to \{0,1\}$ be whether (1) or not (0) $\ d$ divides the input. There exists no $N \in \Bbb{N}$ such that $\forall x \geq N$ we have $$f(x) = \sum_{d \mid p_{\pi(\sqrt{x+1})}\#} (d \mid x^2 - 1) = 0 \pmod 2$$ This is a strange conjecture I've come up with that relates to the twin prime problem. Attempt. Suppose the opposite, then we may augment the summation bound of $\pi(\sqrt{x + 1})$ all the way to $\pi(x-2)$, based upon a sieve-of-Eratosthenes argument. Either way, you'll get $f(x) = 0$. There are a growing number of primes that occur between $\lfloor\sqrt{x + 1}\rfloor + 1 \dots x - 2$. If $g(x) =f(x)$ written with the next prime $q = p_{\pi(\sqrt{x + 1}) + 1}$, we have: $$ 0 = f(x) = g(x) = (1 + (q \mid x^2-1))f(x) = f(x) + (q\mid x^2 - 1) f(x) \\ \ = 0 + \sum_{d \mid p_n\#}(qd\mid x^2 - 1), \text{ where } n \equiv \pi(\sqrt{x + 1}). $$ But we can turn this summation back from whence it came into a product: $$ 0 = g(x) = \prod_{2 \leq p \leq p_n} (1 + (qp \mid x^2 - 1)) \pmod 2 $$ This implies that there exists $p \leq p_n$ such that $(qd \mid x^2-1)$ where $q = p_{\pi(p) + 1}$ is the next prime. Now repeat the procedure, to get: $$ h(x) = (1 + (r|x^2 -1))g(x) = 0 = g(x) + (r\mid x^2 - 1) g(x) \\ \ = \prod_{2 \leq p \leq p_n} (1 + (rqp\mid x^2 - 1)) \pmod 2 $$ which means that there exists $p \leq p_n$ such that $rqp = p_n$ where q, r respectively are the next two primes. Now do this repetitively until you use up all the primes in range $\lfloor \sqrt{x + 1} \rfloor + 1 \dots x -2$. All together, this means: There exists $N \in \Bbb{N}$ such that for all $x \geq N$ we have that: $$ p\cdot \prod_{i= \pi(\sqrt{x + 1}) + 1}^{\pi(x - 2)} p_{i} $$ divides $x^2 - 1$ for some prime $p \leq \sqrt{x + 1}$. Or in terms of primorial, we have that: $$ \exists N \in \Bbb{N}:\forall x \geq N, \exists p \leq \sqrt{x + 1}: $$ $$ p\frac{(x-2)\#}{\sqrt{x + 1}\#} \mid (x^2 -1) $$ To someone experienced with numbers, this seems like an absurdity, but I'm not quite sure how to prove it. The primorial notation is just $(x-2)\#:= p_1 p_2 \cdots p_{\pi(x-2)}$ for example. Proving (the opposite of) this requires estimating $\pi(x-2) - \pi(\sqrt{x + 1})$ perhaps. Or can we argue by divisibility that given $x = N$; $x^2 -1$, $(x + 1)^2 -1$ and $(x + 2)^2 - 1$ and so on can't all share the above property. Any ideas?

Is some twin prime average the sum of two twin prime averages, two ways?

Accoring to this question and a linked duplicate, it's been verified empirically up to some number that all twin prime averages greater than six, are the sum of two smaller twin prime averages. I was curious whether or not these formed a tree (with twin prime pairs at the vertices and the sum relation the edges). In order for these to form a tree, for every twin prime average, we would only be able to find one pair of smaller twin prime averages which summed to it. Can you find a counterexample, namely any twin prime average which is a sum of two smaller twin prime averages, more than one way?

Help me (dis)prove a conjecture about square numbers

Let $S=k*m+p$ be any number where $k,m\in\mathbb{N}$ and p is a prime number. My claim is the following: There exists some nondecreasing function $f:\mathbb{N}\mapsto\mathbb{N}$ with $f(m)\to\infty$ and $\frac{f(m)}{m}\to 0$ for $m\to\infty$, such that for any $m\in\mathbb{N}$ the number of primes that satisfy $p\leq f(m)$ and for at least one value of $k\in\mathbb{N}$, S is a square number that is coprime to m is less than some constant $\Phi\in\mathbb{N}$. I posted this about an hour ago but it was written poorly with many mistakes and I hope that this is a much better way of presentation. My guess is that Φ could be huge, if the claim holds true. Although I think that there is probably a counter example that I am not seeing. If there is not, then I would suspect $f(m)=log(m)$ defined for $m\geq T$ for some $T\in\mathbb{N}$ to be a candidate for this kind of slowly growing function.

Triple integral of the great-circle distance function

Numerical integration suggests that $$\mathcal U=\int_0^\pi\int_0^\pi\int_0^\pi\arccos\left(\cos x\cdot\cos y+\sin x\cdot\sin y\cdot\cos z\right) dx dy dz\stackrel{\small\color{gray}?}{=}\frac{\pi^4}2\tag1$$ (note that the function being integrated represents the great-circle distance$^{[1]}$\!^{[2]}$\!^{[3]}$ in spherical coordinates). How can we prove it? Is it possible to find a closed form for this one? $$\mathcal W=\int_0^{\tfrac\pi2}\!\int_0^\pi\int_0^\pi\arccos\left(\cos x\cdot\cos y+\sin x\cdot\sin y\cdot\cos z\right) dx dy dz\tag2$$

Can we prove that repdigit-numbers cannot be Carmichael-numbers?

A rep-digit number is of the form $$b\cdot \frac{10^a-1}{9}$$ with an integer b with $1\le b\le 9$ and a positive integer a. In the decimal expansion , digit b occurs a times and no other digit. Conjecture : A rep-digit number cannot be a Carmichael-number I checked upto $a=5\ 000$ ($5\ 000$ digits) without finding a Carmichael-number of this form (in fact , not even a Poulet-number). Can we prove that there actually is none ? We can rule out $b=9$ and b even since a Carmichael number must be odd and squarefree and $b=9$ implies divisor 9.

What is the radius of the circle $|z - z_0| = \rho |z - z_1|$? A conjecture based on street fighting mathematics.

What is the radius of the circle $|z - z_0| = \rho |z - z_1|$? My conjecture is $$\text{radius} = |z_1 - z_0| \cdot \frac {\rho ^2}{(\rho -1)^2(\rho + 1)^2}$$ which I request help verifying, proving, or correcting. Note: Formulas exist; I'm asking for help with this approach, as described below. Let $d = |z_1 - z_0|$. Using the approach taught in Street Fighting Mathematics, I deduced the following: The radius is obviously a function of d and ρ. It must be undefined when $\rho = 1$. This also implies that ρ is unitless. It must be linear in d, since the radius is in units of linear distance, and d is as well (whereas ρ is unit less). It must be symmetric when switching z_0, z_1, implying $f(\rho) = f(\frac 1 \rho)$. It must approach 0 when $\rho \to 0$ or $\rho \to \infty$. It must approach ∞ when ρ approaches 1 (illustrated by Circle of Appolonius diagrams). Asking What function $f(x) = f(1/x)$ has limits $\lim_{x \to 0} f(x) = 0, \lim_{x \to \infty} f(x) = 0$, and $\lim_{x \to 1} f(x) = \infty$? , I got some candidate functions, took the simplest, realized I needed to square ρ to makes things work (which is intuitive given that distance requires taking a square root, and so e.g. the standard equation of circles is in r^2), and got this candidate: $$\text{radius} = \frac d {\rho^2 + \frac 1 {\rho^2} - 2}\\ = d \cdot \frac {\rho ^2}{(\rho -1)^2(\rho + 1)^2}.$$ Can you verify or correct this? Is there a way I could develop this approach into a proof?

Conjecture: $\,\lim\limits_{n\to\infty}\int_0^1 (1+|\sin{nx}|)^{-2}\mathrm dx=\frac{4}{3\pi}$

I was playing with integrals, and came up with $$L=\lim_{n\to\infty}\int_0^1 \frac{1}{(1+|\sin (nx)|)^2}dx.$$ Conjecture: $L=\dfrac{4}{3\pi}$ Is my conjecture true? Remarks on numerical investigation: Desmos and Wolfram don't do a good job with numerical investigation of this limit, but we can consider the series $f(n)=\dfrac{1}{n}\sum\limits_{k=1}^n \dfrac{1}{(1+|\sin{k}|)^2}$. $f(10^3)\approx0.999568\left(\frac{4}{3\pi}\right)$ $f(10^6)\approx0.999999635\left(\frac{4}{3\pi}\right)$ $f(10^9)\approx0.999999999807\left(\frac{4}{3\pi}\right)$ This suggests that $\lim\limits_{n\to\infty}f(n)=\frac{4}{3\pi}$. Using Riemann sums, we have $\lim\limits_{n\to\infty}f(n)=L$. My attempt: I tried to use $\,\sin nx = \dfrac{1}{2i}(e^{nxi}-e^{-nxi})\,$ in $\;\displaystyle\int_0^1 \dfrac{1}{(1+|\sin (nx)|)^2}\,\mathrm dx\;,\;\;$ to no avail. I also tried to use complex numbers in the series $f(n)$, as in answers to a question about $\sum_{n=1}^{\infty} \frac{\cos (n)}{n}$, to no avail.

Conjecture about the mean value of an almost periodic function (the "Mountains of Guilin")

Consider the function $f_{p_j,n}(x)=|\sin (p_1x)+\sin (p_2x)+\dots+\sin (p_nx)|$ where p_j is any sequence such that no two p are rational multiples of each other where the p_j are linearly independent over $\mathbb{Q}$ (so the function is almost periodic). (After reading @mollyerin's answer, I changed the condition on p_j.) For example, here is the graph of $f_{2^{1/j},\color{red}{5}}(x)$: And here is the graph of $f_{2^{1/j},\color{red}{10}}(x)$: I call this kind of function $f_{p_j,n}(x)$, the "Mountains of Guilin". Now consider the mean value of $f_{p_j,n}(x)$. I have evidence that suggests that: For any given value of n, the mean value of $f_{p_j,n}(x)$ is independent of the choice of sequence p_j (as long as the p_j are linearly independent over $\mathbb{Q}$). The mean value of $f_{p_j,\color{red}{2}}(x)$ is $8/\pi^2$. I have not been able to find a general expression for the mean value of $f_{p_j,n}(x)$ in terms of n, but I have the following conjecture: $$\color{red}{\lim_{n\to\infty}\frac{\text{mean value of $f_{p_j,n}(x)$}}{\sqrt n}=\frac{1}{\sqrt \pi}}$$ Is my conjecture true? Numerical evidence for my conjecture: Using desmos, I approximated the mean value of $f_{2^{1/j},n}(x)$ as $M_n=\frac{1}{10^7}\sum\limits_{k=1}^{10^7}|\sin (2^1k)+\sin (2^{1/2}k)+\dots+\sin (2^{1/n}k)|$ Letting $L(n)=\dfrac{M_n}{\sqrt n}$, we have: $L(1)\approx 1.128379\left(\frac{1}{\sqrt \pi}\right)$ $L(2)\approx 1.015898\left(\frac{1}{\sqrt \pi}\right)$ $L(10)\approx 1.006373\left(\frac{1}{\sqrt \pi}\right)$ $L(100)\approx 1.000334\left(\frac{1}{\sqrt \pi}\right)$ This suggests that my conjecture may be true, but I don't know how to prove it. Visual representation of the mean value: If my conjecture is true, then there is a nice way to visually represent the mean value of the function. Draw a circle of area n with its centre on the x-axis. A horizontal line through the top of the circle represents, approximately, the average value of the function.

Can you beat every Tax Collector game?

There's a one-player math game called Tax Collector, and recently I was intrigued by it. Let me explain the game, and then I'll ask my question. To start, choose a number to be your ceiling - the game will use all numbers from 1 to x, where x is your ceiling. Then, claim a number to add to your score. The Tax Collector then claims all the factors of that number, and adds them to their score. Claimed numbers cannot be taken again. Note that you cannot take a number with no unclaimed factors. This means that you can only take one prime number at most (with a factor of 1), and all the others are guaranteed to go to the Tax Collector. The game ends when you cannot claim any numbers, and all the unclaimed numbers go to the Tax Collector. Whoever has a greater total wins. I started wondering if this game could ever be impossible to win. Instantly, I realized it could be - if your ceiling is 1, then you can't take anything and the Tax Collector wins, 1 - 0. However, because you don't have a chance to make a move, I considered the game with a ceiling of 1 to not count as a real game. So the question moved to 2 and upwards. I was stopped once again by the game with a ceiling of 3, as it also proved impossible to win. Your two options were to pick 2 or 3 - picking 3 was the better choice. Then, you get 3 points, the Tax Collector gets 1 point, and the Tax Collector gets two as well, since it has not factors left. Final score: 3 - 3. However, after this, I tried greater numbers, and the games were always beatable, usually by a rather large margin. So here's my question: After the games with ceilings 1 and 3, are there any ceilings that leave the game impossible to beat, no matter how well you play? I would assume no, since the prime numbers get scarcer as the numbers get larger, and primes are the Tax Collector's main source of income. However, I don't know how to prove that all games to infinity are beatable - and maybe there's an unbeatable one out there! I would really appreciate help with this question. Maybe there's something obvious I'm not seeing, but I feel like this is more complicated than the game is itself.

Conjecture about determinant of matrix with column j with all numbers not divisible by $j+1$

Consider an $n \times n$ matrix A_n with elements $a_{i,j}$ such that $a_{1,j},a_{2,j},a_{3,j},\ldots$ is the sequence of numbers not divisible by $j+1$ in increasing order starting from 1 (e.g. $1,2,4,5,7,8,10,\ldots$ for $j = 2$). For fun, I have computed the determinant for $n \le 8$ and then conjectured that: $$\lvert A_n \rvert = (-1)^{n+1}$$ Is the conjecture true? How would you prove it?

Large gaps between small primes

Does there exist a positive integer $n>5$ such that the sum of the two largest primes less than n equals n? If yes, lovely! If not, what is the largest prime gap possible between the two largest primes less than n? The first question could also be rewritten as $2*p - n = d$ where p is the largest prime less than n and d is the difference between p and the second largest prime less than n.

Numbers with a unique partition as a sum of two squares

The well known Ramanujan tau function $\tau(n)$ is defined as the nth Fourier coefficient of the modular discriminant $\displaystyle \Delta(q)=q\prod_{m=1}^\infty (1-q^m)^{24} = \sum_{n=1}^\infty \tau(n)\,q^n\tag{1a}$ In the spirit of my previous posts(here (1) and here (2) for example) concerning the parity of certain coefficients of modular forms, I was naturally led to investigate this subsequent conjecture Let us introduce the following convolution identity, see here (3) $\displaystyle\Big(\sum_{n=1}^{\infty} \tau(n) q^n\Big)^2+\sum_{n=1}^{\infty} \tau^2(n) q^{2n}=2\sum_{n=0}^{\infty} \sum_{k=0}^{n} \tau(k+1) \Big(\tau(2n-k+1) q^{2n+2}+\tau(2n-k+2) q^{2n+3}\Big) \tag{1b}$ Think of it as a generalisation of the cauchy product and power sum symmetric polynomials. In generalc consider a sequence of complex terms $a_0, a_1, a_2,...$, then the ff convolution identity holds $\displaystyle\Big(\sum_{n=1}^{\infty} a_{n}\Big)^2+\sum_{n=1}^{\infty} a^2_{n}=2\sum_{n=0}^{\infty} c_{n}$ where $\displaystyle c_{n}=\sum_{k=0}^{n} a_{k+1} \Big(a_{2n-k+1}+a_{2n-k+2}\Big)$ given of course that the sums $\displaystyle\Big(\sum_{n=1}^{\infty} a_{n}\Big)^2$ and $\displaystyle\sum_{n=1}^{\infty} a^2_{n}$ converge. A little bit of experimentation leads one to the ff conjecture The nth coefficient in the partial sum of the series $\displaystyle \sum_{n=0}^{\infty} \sum_{k=0}^{n} \tau(k+1)\Big(\tau(2n-k+1) q^{2n+2}+\tau(2n-k+2) q^{2n+3}\Big)\tag{1c}$ is odd if and only if the power of its last term is $\stackrel{\mathrm{def}}{=}2z$ where $z\equiv 1\pmod{4}$ with a unique partition as a sum of two squares x^2+y^2, a sequence of integers $\color{orange}{1}, \color{orange}{5}, \color{orange}{9}, \color{orange}{13}, \color{orange}{17}, \color{orange}{29}, \color{orange}{37},....$ which can readily be found in this oeis entry $\displaystyle \sum_{n=0}^{\infty} \sum_{k=0}^{n} \tau(k+1)\Big(\tau(2n-k+1) q^{2n+2}+\tau(2n-k+2) q^{2n+3}\Big)=q^{2×\color{orange}{1}}-24q^3+828q^4-7520 q^5+103662q^6-492912q^7+3512352q^8-8147520q^9+25870905q^{2×\color{orange}{5}}+19335800q^{11}-193971120q^{12}+6341175146q^{13}-465787812q^{14}-2153273040q^{15}+12714981120q^{16}-11761115712q^{17}-6692143617q^{2×\color{orange}{9}}+68609297160q^{19}-....$ Question: How do we prove it? Modified conjecture Following Somos' proof, the original conjecture may be modified as follows The nth coefficient of the partial series of $(1c)$ is odd if and only if $r(n)$ the number of integer solutions $n=x^2+y^2$ where $0< x \le y$ is odd since $\displaystyle \sum_{n=0}^{\infty} \sum_{k=0}^{n} \tau(k+1)\Big(\tau(2n-k+1) q^{2n+2}+\tau(2n-k+2) q^{2n+3}\Big) \equiv \sum_{n=1}^\infty r(n)q^n \pmod 2$ By using the RHS of our convolution identity (1b) we can determine every nth coefficient of the LHS with ease. For example let us determine the counterexample(spotted by Somos) to the unmodified stated conjecture $\displaystyle \sum_{k=0}^{424} \tau(k+1)\tau(849-k)q^{850}=-905126639660151664169216877 75q^{850}$

Prime numbers in rearrangements of Smarandache numbers

Take the first n integers, and concatenate them to form the n_{th} Smarandache number. Then, I have the following Conjecture For $n>2$, the digits of each Smarandache number can be rearranged in blocks of digits, such that each block forms some prime number. For instance, consider $n=1234$; it can be rearranged as 2341, with blocks 23 and 41, which are both prime numbers. The blocks could also be 2, 3 and 41. It can be expected an increasing number of ways to form blocks as n grows. I have written a Python program to check the validity of the conjecture, but it seems to be too slow from $n=15$ on (I share it below the questions). Questions Has been this already studied somewhere? Can you share some reference? Is the conjecture plausible for big values of n? Can you share a faster way / program to check the validity of the conjecture? Or a possible strategy to prove it. As a side note, and incidentally, the Python program finds mainly blocks that involve "quasi-Smarandache" numbers, where a quasi-Smarandache number can be defined as some integer that looks similar to some Smarandache number but changing the order of some digit, or substracting some. (F.i., 1234657, 12345678109,...). It surprises me that they seem to be more abundant than one could "a priori" expect. Thanks in advance! EDIT As stated at the comments, a second interesting conjecture can be posed: Conjecture 2 For $n>2$, the digits of each Smarandache number can be rearranged in blocks of at least $\lfloor\log(n)\rfloor$ digits, such that each block forms some prime number. I have written another Python program to check the validity of the conjecture 2, but it seems to be too slow from $n=15$ on (I share it below the questions too). Any insight on Conjecture 2,or an improvement on the program developed to check it for higher values of n, would also be welcomed. Can all primes greater than 5 be decomposed into the difference of a primorial and a prime?

Conjecture: For all primes $p_n≥7$, there is at least one solution to the equation $$ p_n = p_k\# - p_m$$ where $p_k\#$ is any primorial, and p_m is any prime number. Has this been explored before? Can it been proven or disproven? I tried it numerically up to $ p_n =2322869$ Interestingly, the additive version of this, $$ p_n = p_k\# + p_m$$ seems to have solutions for most primes but not all; the lowest of which lacks a solution is $p_n=149$.

If 3 numbers of the form $\frac{1}{q^2+1}$ have a mean of $\frac{1}{2}$, will one of them always be $\frac{1}{2}$?

I recently came onto a set of numbers with an interesting pattern, but I can't prove it always holds true. I'd appreciate any help in figuring it out. Let the set S $$S = \left \{ \frac{1}{q^2+1} , q \in \mathbb{Q^+} \right \}$$ And three elements of that set $a,b,c \in S$ My conjecture is that if their average is equal to $\frac{1}{2}$, then at least one of them must be equal to $\frac{1}{2}$. $$\frac{a+b+c}{3} = \frac{1}{2} \implies (a =\frac{1}{2}) \lor (b=\frac{1}{2}) \lor (c=\frac{1}{2})$$ Do you have any idea on how to prove, or disprove that claim? Edit to provide examples: You can easily generate sets of numbers that verify the conjectured pattern. Let $f(q) = \frac{1}{q^2+1}$ for rational q. All triplets of the form $(f(1), f(q), f(\frac{1}{q}))$ have an average of $\frac{1}{2}$.

Computing the number of monomials of a certain polynomial

I have computed the number of monomials of the polynomial: $$\prod_{0 \le k_1 \lt \ldots \lt k_{n-t} \le n-1} \left(\sum_{j=1}^{n-1} x^{k_j} \right)$$ with $t = 1$ for $n=2,3,4,5,6$ and found it equal to $1,5,11,19,29$ respectively. Each factor is a combination of $n-t$ monomials chosen among $1,x,x^2,\ldots,x^{n-1}$. The product is over all possible combinations. For example, with $n=3$ we have: $$P(x) = (1+x)(1+x^2)(x+x^2) = x^5 + 2 x^4 + 2 x^3 + 2 x^2 + x$$ and therefore there are 5 monomials. Looking at OEIS, one could for example conjecture that the number of monomials is: $$n-2+(n-1)^2 = n^2-n-1$$ Is the conjecture true? In general, is it possible to find a formula as a function of n for any given t such that $n \gt t \ge 1$?

Does "all derivatives vanish" $\iff$ "the rate of change is smaller than any function in P"?

Let $f: \mathbb R \to \mathbb R$ be C^∞. Suppose f is not constant on any interval containing x_0. Are the following two statements equivalent: (i) All derivatives of f at x_0 vanish. (ii) The rate of change of f at x_0 is smaller than any polynomial function. More formally, if $g(h) := f(x_0 + h) - f(x)$, for any polynomial function $P(h)$, for any interval I containing x_0, there exists $x_1 \in I$ such that for all $h < |x_1 - x_0|$, $0 < |g(h)| < |P(h)|$. Background: I am exploring flat functions and conjecture that the "reason" their derivatives vanish despite the function being non-constant is that their rate of change is too small to be captured by any polynomial. I am drawing on asymptotic concepts such as O, o, etc. See also: Is there an intuitive way of visualizing how a function that is flat at some given point can be something other than a constant function?

How can you prove or disprove that half of all natural numbers can be expressed as the sum of three squares minus the product of their roots?

I do not have much formal mathematical education beyond high school, but I do like watching math YouTube videos. I recently read a comment on a video asking if anyone could prove that there are no positive integer solutions to the equation a2 + b2 + c2 - abc = 1. It took me a while, but I found a proof, and I then used a similar method to prove a more general claim. For any given positive integer n, there exists a set of three positive integers a, b, and c satisfying the equation a2 + b2 + c2 - abc = n if and only if there exists such a set where a2 + b2 ≤ n. For example, if there are no positive integer solutions to the equation a2 + b2 + c2 - abc = 6 where a2 + b2 ≤ 6, then there are no positive integer solutions to that equation at all. My proof is too long to paste into this post, so here is a link to a PDF of it: htt ps://www.dropbox.com/scl/fi/9wsm5b4zsz9xpc0r7p0rk/naturalnumberproblem.pdf?rlkey=0g

wqktvfu9215fskihlt2fvu3&dl=0 Since there are only finitely many pairs of positive integers who squares sum to a value less than or equal to a given number, you only need to check finitely many cases to determine whether there is a solution for a given n. For example, for n = 6, you only need to check {a = 1, b = 1} and {a = 1, b = 2}. Solving for c shows there are no positive integer solutions. After discovering this, I wrote a program to that checked whether there were solutions for each n from 1 to 100. I was hoping to find a pattern in the numbers that have or don't have solutions, but I didn't find much. However, I did notice that about half of the numbers had solutions. That intrigued me, so I increased the range of my search to see if this percentage held. Here are the results: From n = 100 to 999, the percentage of numbers with solutions stays between 49.3% and 52.5%. From n = 100 to 9999, the percentage of numbers with solutions stays between 49.8% and 50.4%. From n = 10000 to 99999, the percentage of numbers with solution stays between 50.1% and 50.7% My conjecture is that this percentage stays around 50% and that the deviations get smaller and smaller over time. I assume there is some way to state this more formally using limits. Does anyone know if what I found has already been discovered and if my conjecture has already proven or disproven? What methods would you even use to do this? As I said, I don't have much formal mathematical education. The math used in the proof linked above is fairly simple. Nothing more 'advanced' than modular arithmetic and proofs by contradiction. My intuition is that proving my conjecture would rely on math I've never even heard of, but maybe there is some (relatively) simple proof out there. I can prove that ~41.6% of all numbers will not have solutions. (I am speaking loosely. I know this needs to be stated more formally with limits.) This is because there are no solutions to the equation when n is congruent to 3 mod 4, 3 mod 9, or 6 mod 9. This was verified by a computer trying every possible solution working from mod 2 to mod 800. Let f(n) count the numbers less than or equal to n that are congruent to 3 mod 4, 3 mod 6, or 3 mod 9. There are no numbers that are congruent to both 3 mod 9 and 6 mod 9. The only numbers that are congruent to both 3 mod 4 and 3 mod 9 are those that are congruent to 3 mod 36, and the only one congruent to both 3 mod 4 and 6 mod 9 are those that congruent to 15 mod 36. Therefore, the limit of f(n)/n as n approaches infinity is equal to 1/4 + 1/9 + 1/9 - 1/36 - 1/36 = 5/12 = ~41.6% One more thing I know (proof in that PDF) is that for all n except n = 2, there are either no positive integer solutions to the equation a2 + b2 + c2 - abc = n or there are infinitely many such solutions. For n = 2, there is only one solution {a = b = c = 1}. I doubt that is relevant to the conjecture, but it does not hurt to mention it. One last thing: I'm tagging this as a number theory question and as a question about Diophantine equations. Let me know if that is incorrect. EDIT #1: I want to add that I looked up the first dozen n with solutions in the OEIS and didn't find anything. Here's a list of all n with solutions up to 100 in case it helps: 2, 4, 5, 8, 10, 13, 14, 17, 18, 20, 22, 25, 26, 28, 29, 32, 34, 37, 38, 40, 41, 44, 45, 49, 50, 52, 53, 54, 58, 61, 62, 64, 65, 68, 70, 72, 73, 74, 76, 77, 80, 82, 85, 88, 89, 90, 92, 94, 97, 98, 100 EDIT #2: My program just finished checking up to n = 1,000,000. From n = 100,000 to 1,000,000 the percentage of numbers with solutions stays between 50.7% and 51.6%. It's getting further from 50%, so I'm starting to doubt my conjecture is true. If anyone wants to run the program themselves, here's a link to txt version of it: https://www.dropbox.com/scl/fi/kb2p277sa6d29ieeedigk/mathprogram.txt?rlkey=sr5su9zny13y75qg0b5k1v0g4&dl=0 It's written in Python. I don't have any formal programming education either. Just started teaching myself Python a few weeks ago, so I apologize if it's confusing or inefficient code. Also, the program will not make much sense unless you've read the section in the linked proof called "A Note on Searching For Satisfactory Triplets." EDIT 3: There was a typo in my post. I said there are no solutions when N is 3 mod 6. I meant to write 6 mod 9. Sorry! EDIT 4: There were also a couple typos in my PDF where I used < when I meant to write ≤, but I have corrected them. (Unfortunately, this somehow created some new typos. It must be an issue with the conversion from .doc to .pdf but I don't think it effects the clarity much.) EDIT 5: Some errors in the proof were fixed, and a new link has been created. This one should be viewable by anyone. EDIT 6: Refined the approximation of how many numbers (less than N for sufficiently large N) don't have solutions from 40% to 41.6%.

Conjecture about non-squarefree numbers.

Conjecture : Let k be a non-negative integer. Then , there is a positive integer j , such that 10^j+k is NOT squarefree. The conjecture is true upto $k=10^6$. We can always find a positive integer $j\le 421$ as desired. If we demand that 10^j+k is not cubefree, then still up to $k=17493$ L, there is a $j\le 6376$ as desired. I am however currently mainly interested in the non-squarefree case. Another approach (which I have not yet tried) is that we determine the k for which $4\mid 10^j+k$, $9\mid 10^j+k$, $25\mid 10^j+k$ is possible and hope that we can "cover" all positive integers. If someone solves this problem for which we need discrete logarithms, an answer would be appreciated and I would gladly upvote and accept it. The non-cubefree case would be a nice bonus.

Computing the least common multiple of the numbers 1 through n for incremental n

I notice a pattern when computing the least common multiple for the numbers 1 through n as we incrementally increase n. The pattern is that the list of factors does not increase unless the incremental next value we include is a prime number to a positive integer power. Also, if it does increase, it only ever increases by 1. Consider the following python code. Notice that when we include 13, the factor list begins to include 13 because 13 is a prime raised to the first power. Notice that when we include 16, the factor list begins to include an additional 2 because 16 is a prime raised to the fourth power. >>> factors(lcm(*range(1,13))) [2, 2, 2, 3, 3, 5, 7, 11] >>> factors(lcm(*range(1,14))) [2, 2, 2, 3, 3, 5, 7, 11, 13] >>> factors(lcm(*range(1,15))) [2, 2, 2, 3, 3, 5, 7, 11, 13] >>> factors(lcm(*range(1,16))) [2, 2, 2, 3, 3, 5, 7, 11, 13] >>> factors(lcm(*range(1,17))) [2, 2, 2, 2, 3, 3, 5, 7, 11, 13] >>> factors(lcm(*range(1,18))) [2, 2, 2, 2, 3, 3, 5, 7, 11, 13, 17] >>> factors(lcm(*range(1,19))) [2, 2, 2, 2, 3, 3, 5, 7, 11, 13, 17] >>> factors(lcm(*range(1,20))) [2, 2, 2, 2, 3, 3, 5, 7, 11, 13, 17, 19] Does the conjecture have a name, and is it true? Stated in another way, we can always construct n+1 by rummaging around among the factors of the numbers 1 through n unless n+1 is a prime power. Further, if it is a prime power, the prime factorization of n+1 will always have just one additional factor than our previous budget had (e.g. 2^4 vs 2^3). (for what it's worth, I was motivated to think about this because of a recent post from

Possible connection between prime numbers in binary and π

I just realized I asked a question with a very similar title a while back. This is not a duplicate. It is another conjecture though. Conjecture: $\lim\limits_{x\to\infty}\mu \{ f(2), f(3), f(5), ... , f(x) \}=\frac{\pi}{2}-1$ where $x\in\mathbb{P}$, $f(x)$ equals the amount of 1s divided by the total number of digits in the binary representation of x. μ is the arithmetic mean and $\mathbb{P}$ represents the set of all primes. Example of $f(x)$ because of my poor explanation (I tried my best): $f(5)\rightarrow 101\rightarrow \frac{\text{number of 1s (or the digit sum)}}{\text{total number of digits}}\rightarrow\frac{2}{3}$ I have no idea why this conjecture would be true but it appears that it may converge, at least for the first 2000 primes. In the picture, the green line is $y=\frac{\pi}{2}-1$ and the black points are $\mu \{ f(2), f(3), f(5), ... , f(x) \}$. My question is whether or not my conjecture is true? Am I missing something obvious here? Also, I find it very interesting that it looks similar to a quasiperiodic function.

Deterministically finding g such that $f(g(x)) \ge x$?

It's just some random thoughts, but I find it confusing. Here's the classical "prove" that every natural number can be described within eleven words: Suppose not, then there's a smallest counterexample n. Then n can be described as "the smallest natural number that cannot be described within eleven words", which is itself in eleven words, contradiction. Of course, the proof above is false. But when I tried to do the same thing mathematically, something confusing happened. Suppose f is an arbitrary injective function $f: \mathbb{N} \to \mathbb{N}$. Let h be a bijection from "all finite logical formula" to $\mathbb{N}$. Let φ_n denote the formula with $f(h(\varphi_n))=n$. For some $M \in \mathbb{N}$ let $p \in \mathbb{N}$ such that $$\varphi_p(x) = \neg\exists m\in\mathbb{N}(m<M \wedge \varphi_m(x) \wedge \neg\exists y\in\mathbb{N}(\varphi_m(y))) \wedge\\ \forall y\in\mathbb{N}(y<x \to \exists m\in\mathbb{N}(m<M \wedge \varphi_m(y) \wedge \neg\exists z\in\mathbb{N}(\varphi_m(z))))$$ (x is the smallest natural number such that there is no formula φ_m with $m<M$ such that φ_m "accurately describes" x, i.e. x is the only natural number that satisfies φ_m.) Let us first assume that $p < M$. If there is an $y \in \mathbb{N}$ that $\neg\exists m\in\mathbb{N}(m<M \wedge \varphi_m(y))$, let y be the smallest such number. Then $\varphi_p(y)$, but $p < M$, contradiction! Therefore every natural number can be accurately described with some formula φ_m with $m<M$, but the number of such formula is finite, contradiction! So $p \ge M$. What does this mean? We have found, constructively, a function $h^{-1} \circ p: \mathbb{N} \to \mathbb{N}$ injective, such that $f(h(h^{-1}(p(M)))) \ge M$ which is $f(p(M)) \ge M$, for every M. This is very counter-intuitive, since such a p is usually found inductively. Is there something wrong in the above construction?

A conjecture for the golden ration via continued fraction $\phi=\frac{1+\sqrt{5}}{2}$

Playing with my own question Got a factored version of the Taylor's series? I found that : Define : $$f(x)=\frac{1}{\sqrt{x-2/x}}$$ Then it seems we have : $$\phi=f(f(\cdots f(\phi)\cdots))$$ Numerical checking is agree so some question : edit : I'm really interested by an generalization the next polynomial are : $$x^4-2x^3+2x,x^5-3x^3+2x,...$$ How to (dis)prove it ? How fast is the convergence if true ? Is there a generalization if true ?

Conjecture: If $a_1\in\mathbb{Z}$ and $a_n=\sec (a_{n-1})$ then the proportion of positive terms approaches $\frac{1}{\sqrt{2\pi}}$ as $n\to\infty$.

I made up the following family of sequences: $a_1\in\mathbb{Z}$ and $a_n=\sec (a_{n-1})$ for $n>1$. I conjecture that, for any $a_1\in\mathbb{Z}$, the proportion of positive terms approaches $\frac{1}{\sqrt {2\pi}}$ as $n\to\infty$. Is my conjecture true? Evidence for my conjecture For $a_1=1$, here is the graph of a_n against n for $1\le n \le 25$. Using Excel, it seems that, the proportion of positive terms approaches a limit as $n\to\infty$, and the limit is independent of the value of a_1. I found that, for $a_1=1, 2, 3, \dots, 25$, among the first 10000 terms, the average proportion of positive terms is 0.398940, which is very close to $\frac{1}{\sqrt {2\pi}}\approx 0.398942$. Another look at the sequence Here are the graphs of $y=\sec x$ and $y=x$. We start at $(1,\sec 1)$, then go horizontally to the line $y=x$, then go vertically to the curve $y=\sec x$, then go horizontally to the line $y=x$, etc. Among the points that we meet on the curve $y=\sec x$, about 0.39894 of them are above the x-axis.

How do I find the focal distance?

I’ll first put the question as it is on the assignment and then ask my question. The following describes certain characteristics of a parabolic radio telescope that an astronomical observatory would like to build. It is presented in two positions: pointing upward and to the horizon. In this first position, the focus reaches a height of 18.4 m and the edge of the reflector is situated 14.5 m from the floor. In the second position, the bottom of the reflector is 2 m from the floor and the top is at 18 m. You should know that the efficiency of a radio telescope depends on the diameter of its reflector. The greater this diameter, the more the radio telescope is able to capture waves coming from remote regions of space. However, the capture quality also depends on the focal distance, which is the distance between the focus and the vertex. This distance must neither be too great nor too small relative to the diameter. In fact, what is important is the ratio of $\frac{focaldistance}{diameter}$, which ideally should be close to 0.5. Then they go on asking, a) Determine the value of this ratio for the radio telescope presented. b) To increase the value of the ratio without reducing the diameter of the reflector, what changes should be made to the shape of the parabola? State a conjecture justifying your point of view, using an example or reasoning. So my question is: How do I find the focal distance of the mentioned parabola? I tried to use the formulas in the book but I was not able to find it. I only found the diameter (18 m - 2 m = 16 m). I have a feeling that the answer is right in front of me but I don’t see it.

Conjecture for Integrals of the Form $\int_{0}^{1}\frac{\ln^n\left(1-x^{2}\right)}{1+x}dx$

Recently I got interested in Logarithmic Integrals from this $\int_{0}^{1}\frac{\ln^4\left(1-x^{2}\right)}{1+x}dx$ and sought out to find Higher Power variations. Let, $$I_n=\int_{0}^{1}\frac{\ln^n\left(1-x^{2}\right)}{1+x}dx$$ Consider the following expression : $$E=\zeta(\alpha_1)\zeta(\alpha_2)...\zeta(\alpha_n)\ln^\alpha2$$ whose weight is $\alpha_1+\alpha_2+...+\alpha_n+\alpha.$ $$\boxed{\text{Conjecture: All I_n can be written as a Linear Combination involving Expression E of weight $n+1$.}}$$ Here are the first few examples : $$I_1=-\frac{1}{2}\zeta\left(2\right)+\ln^{2}2$$ $$I_2=2\zeta\left(3\right)-2\zeta\left(2\right)\ln 2+\frac{4}{3}\ln^32$$ $$I_3=-\frac{27}{4}\zeta\left(4\right)+12\zeta\left(3\right)\ln2-6\zeta\left(2\right)\ln^22+2\ln^42$$ $$I_4=72ζ\left(5\right)-24ζ\left(3\right)ζ\left(2\right)-54ζ\left(4\right)\ln2+48ζ\left(3\right)\ln^{2}2-16ζ\left(2\right)\ln^{3}2+\frac{16}{5}\ln^{5}2$$ $$I_5=-\frac{1185}{4}ζ\left(6\right)+120ζ^{2}\left(3\right)+720ζ\left(5\right)\ln2-240ζ\left(3\right)ζ\left(2\right)\ln2-270ζ\left(4\right)\ln^{2}2+160ζ\left(3\right)\ln^{3}2-40ζ\left(2\right)\ln^{4}2+\frac{16}{3}\ln^{6}2$$ $$I_6=6480ζ\left(7\right)-2160ζ\left(5\right)ζ\left(2\right)-1620ζ\left(4\right)ζ\left(3\right)-3555ζ\left(6\right)\ln2+1440ζ^{2}\left(3\right)\ln2+4320ζ\left(5\right)\ln^{2}2-1440ζ\left(3\right)ζ\left(2\right)\ln^{2}2-1080ζ\left(4\right)\ln^{3}2+480ζ\left(3\right)\ln^{4}2-96ζ\left(2\right)\ln^{5}2+\frac{64}{7}\ln^{7}2$$ Could the Conjecture be Proved or Disproved. I had made a Similar Conjecture for another Logarithmic Integral of Similar Form but it stopped working from Weight 8.

Are there any general results that relate the amount of solutions to a diophantine equations to the average growth rate of such solutions?

Background Recently, I asked a question about the average growth rate of the solutions to the following sequence of Egyptian fraction equation: $$ \sum_{k=1}^{n} \frac{1}{x_{k}} = q. \tag{1} $$ Here, we have $x_i \in \mathbb{N}_{>0} $ for all $ 1 \leq i \leq n $, and $ \ 0 <x_{1}<x_{2}<\cdots<x_{n} $. So far, the question hasn't received any answers. What is known, however, are bounds for the amount of solutions to (1). If we define $$\mathsf{E}_{n}(q)=\left\{ \{x_1 , x_2 , \dots , x_n \} \in \mathbb{N}^n_{>1}: \sum_{k=1}^{n} \frac{1}{x_{k}} = q, \ 0 <x_{1}<x_{2}<\cdots<x_{n} \ \right\}, $$ then according to p.8 of this article we have $$ e^{c \frac{n^{3}}{\log(n)}} < | \mathsf{E}_{n}(1) | < c_{0}^{(1+\epsilon)2^{n-1} }, \tag{2} $$ where $c_{0} \approx 1.264$. Question Let's leave aside the specific case of Egyptian fractions (as described above) for a moment, and consider a more general case. Let $a(n)$ be a set consisting of sequences of solutions to a sequence of diophantine equations $d(n)$, with $|a(n)| = o(f(n))$ and $|a(n)| = O (g(n))$. Can anything be said, in this general case, about the growth rate of the average size of the solutions to $d(n)$, and how this growth rate relates to $f(\cdot)$ and $g(\cdot)$? Are there any results on this question, or any conjectures?

Who can prove or disprove this conjecture?

Let m be a positive integer such that $p:=8m^2+1$ is prime. Conjecture : We always have $$2^{2m^2}\equiv 1\pmod p$$ I could only establish $$2^{4m^2}\equiv 1\pmod p$$ following from Euler's criterion , but I could not rule out $2^{2m^2}\equiv -1\pmod p$ Motivation : A proof would show that $$(2m^2+1)(8m^2+1)$$ is a Poulet-number whenever both factors are prime. Verification : The conjecture is true upto $m=10^{10}$.

Ec primes multiple of 67 and $1\pmod{67}$

Ec primes are primes of the form: $(2^n-1)\cdot 10^d+2^{n-1}-1=ec(n)$, where d Is the Number of decimal digits of 2^{n-1}. I conjecture that there are infinitely many primes of this form with n either $\equiv 0\pmod {67}$ or $\equiv 1\pmod {67}$ Verification: for $n=67, 6231,51456, 79798, 285019$ $ec(n)$ is probable prime. Is that another coincidence or law of small numbers? The multiples of 67, that Is 6231 and 51456 are also multiple of 3. And 79797, 285018 are divisible by 3 too. Is there a particular reason? $79797=201\cdot 397$ Is a palindromic Number Just a curio.

Does it make sense to divide mathematical theorems into those susceptible to experimental conjecture and those that are not?

I read the following in a good book: ”let's start from zero", the authors are Vinicio Villani and Maurizio Berni (pisan mathematicians) but I don't know if the book is also marketed outside Italy. I don't think I'm exaggerating when I say that the shocking discovery of the existence of incommensurable segments gave a decisive impulse to the development of all mathematics, understood as a theoretical, hypothetical-deductive discipline. In fact, the validity of other theorems of classical geometry (starting from those of Thales and Pythagoras) can be empirically verified on a drawing through experimental measurements, albeit approximate. Instead, the question of the commensurability or incommensurability of two segments eluded us then, as it eludes us today and will elude us forever to every attempt at experimental verification, given the inevitable imprecision of every physical measurement" When I first read it, in my mind I enthusiastically endorsed this statement. But then I thought about it and I had some doubts. The statement seemed to imply that there are two classes of theorems, the one whose truthfulness can be suggested by so-called experimental and numerical arguments (even if obviously without a demonstration we are always at zero), and those which are totally precluded by a such approach that can suggest conjectures. But does this make sense? Really "the theorem the root of 2 cannot be expressed as a ratio between integers" is in this sense qualitatively different from the Pythagorean theorem? It is true that I can set about constructing squares on right-angled triangles and make measurements that lead me to conjecture the validity of the theorem, but I can also patiently set about searching for two integers such that the square of their ratio is two, and after long labors conjecture that such a pair of integers does not exist. All this if I didn't have an easy proof available but it's not the point here now. In short, the question is: does the division of mathematical theorems into two classes, those that can be conjectured experimentally and those that cannot, make sense?

A curious coincidence: $\prod\limits_{k=1}^\infty\left(1+\int_{k}^{k+1}\left(\frac{\sin (\pi x)}{x}\right)^2\mathrm dx\right)\overset{?}{=}\pi/2$

It is known that $\int_0^\infty \frac{\sin x}{x} \mathrm dx=\dfrac{\pi}{2}$ (proof) and $\int_0^\infty\left(\frac{\sin x}{x}\right)^2\mathrm dx=\dfrac{\pi}{2}$ (proof). Numerical investigation suggests that we also have: $$\prod\limits_{k=1}^\infty\left(1+\int_{k}^{k+1}\left(\frac{\sin (\pi x)}{x}\right)^2\mathrm dx\right)=\dfrac{\pi}{2}$$ But I do not know how to prove this. $\int\left(\frac{\sin (\pi x)}{x}\right)^2\mathrm dx$ cannot be expressed in terms of elementary functions. Is this infinite product really equal to $\dfrac{\pi}{2}$?

Weaker Version of "Goldbach's Other Conjecture"

Taken from problem 46 on Project Euler: It was proposed by Christian Goldbach that every odd composite number can be written as the sum of a prime and twice a square. $9 = 7 + 2 \times 1^2$ $15 = 7 + 2 \times 2^2$ $21 = 3 + 2 \times 3^2$ ... It turns out that the conjecture was false. Now, suppose the phrase "twice a square" was replaced with "two squares." In other words, this revision of the conjecture would state that all odd composites C can be written in the following form: $C=p+a^2+b^2$ Where p is a prime and a and b can take on any non-negative integer values. Making the substitution $a=b$ reduces this problem to the classical conjecture. Now, is this weaker conjecture true? My Attempt at the Problem: Let $d=a^2+b^2$. A well-known theorem states that the sum of two squares can be rewritten as $2^{e_0} \left({p_1}^{e_1}...{p_n}^{e_n} \right) \left({q_1}^{2 o_1}...{q_n}^{2 o_n} \right)$, where p_i is a prime of the form $4k+1$ and q_i is a prime of the form $4k+3$. We can therefore write the conjecture as follows: $C=p+d$ $C=p+ 2^{e_0} \left({p_1}^{e_1}...{p_n}^{e_n} \right) \left({q_1}^{2 o_1}...{q_n}^{2 o_n} \right)$ $C=p+ 2^{e_0}g$ Where g is any integer such that $g=1 \left(\text{mod } 4 \right)$. Letting $p=2$ and $e_0=0$ shows us that the conjecture is true when C is of the form $4k+3$. From here I am not sure where to go. Any clues?

Conjecture: Given any $2n+1$ points, we can always draw n non-intersecting circles whose diameter endpoints are $2n$ of those points.

Is the following conjecture true or false: Given any $2n+1$ coplanar points, we can always draw n non-intersecting circles coplanar with the points, whose diameter endpoints are $2n$ of those points. We consider tangent circles to be non-intersecting. This is a generalization of my earlier question about the case $n=2$. That question is currently unanswered. I wonder if it is easier to prove the general case. Example: Another example: I cannot find a counter-example, nor can I prove the conjecture. I made a generator of seven (pseudo)random points. (If, instead, we were given $2n$ points, the conjecture would not be true: for example, if the $2n$ points were the vertices of a regular $(2n-1)$-gon plus the centre, then we could not draw n non-intersecting circles.)

Poulet numbers of the form $3p$, where p is a palindrome

A Poulet-number is a composite number N satisfying $$2^{N-1}\equiv 1\mod N$$ A palindrome is a positive integer with a digit string in base 10 which remains the same if it is written down backwards. If $3p$ is a Poulet-number and p a palindrome , it seems that p must begin (and therefore end) with digit 7. The examples upto $p=10^{18}$ are : 23001 7667 [11, 1; 17, 1; 41, 1] 212421 70807 [11, 1; 41, 1; 157, 1] 23054601 7684867 [17, 1; 251, 1; 1801, 1] 235201461 78400487 [11, 1; 41, 1; 131, 1; 1327, 1] Why is p always of the form $7...7$? Why is p divisible by 41 , if it is divisible by 11 ? Any counter-example?

"Twin binomial coefficient conjecture": There are no binomial coefficients that differ by 2, excluding $\binom{n}{1}$ and $\binom{n}{n-1}$.

Consider the binomial coefficients, excluding those of the form $\binom{n}{1}$ and $\binom{n}{n-1}$. There are some that differ by 1, for example $\binom{7}{2}-\binom{6}{3}=21-20=1$. There are some that differ by 3, for example $\binom{31}{2}-\binom{11}{5}=465-462=3$. There are some that differ by 4, for example $\binom{5}{2}-\binom{4}{2}=10-6=4$. There are some that differ by 5, for example $\binom{6}{2}-\binom{5}{2}=15-10=5$. There are some that differ by 6, for example $\binom{9}{3}-\binom{13}{2}=84-78=6$. Etc. But I cannot find any that differ by 2. I checked the first 120 rows of Pascal's triangle. So, is the following conjecture true or false: There are no binomial coefficients that differ by 2, excluding those of the form $\binom{n}{1}$ and $\binom{n}{n-1}$. Call it the "Twin binomial coefficient conjecture", if you will. Context: I was playing with Pascal's triangle, trying to approximate the median of the numbers in the first n rows, and I noticed a lack of differences of 2.

$\int_0^{\pi/2}\int_0^{\pi/2}\frac{(\tan\alpha)(\tan\beta)}{\tan\alpha+\tan\beta} d\alpha d\beta=(0.9999999913...)(\pi/2)$? Seriously?

In the diagram, α and β are independent uniformly random real numbers in $\left(0,\frac{\pi}{2}\right)$. What is $\mathbb{E}(h)$? Superimposing a cartesian coordinate system, the equations of the lines are $y=(\tan\alpha)x$ and $y=(-\tan\beta)(x-1)$, so the y-coordinate of their intersection is $\frac{(\tan\alpha)(\tan\beta)}{\tan\alpha+\tan\beta}$. So we have $$\mathbb{E}(h)=\frac{4}{\pi^2}\int_0^{\pi/2}\int_0^{\pi/2}\frac{(\tan\alpha)(\tan\beta)}{\tan\alpha+\tan\beta} d\alpha d\beta$$ Desmos says $I=\int_0^{\pi/2}\int_0^{\pi/2}\frac{(\tan\alpha)(\tan\beta)}{\tan\alpha+\tan\beta} d\alpha d\beta$ is $(0.9999999913...)(\frac{\pi}{2})$. Is that a computer error, and the result is exactly $\frac{\pi}{2}$? I don't know how to evaluate the integral. Wolfram evaluates the inside integral but doesn't evaluate both integrals. If Desmos is not very reliable, then maybe my earlier weird conjecture is actually true. (This question was inspired by a question about random points in a square.) Edit: In the comments, @G.Gare notes that Mathematica says the integral I is exactly $\pi/2$. Can we prove it? Maybe an intuitive geometrical argument? Edit2: I seek to generalize this result here.

Conjecture: If x_k are random in $(0,\pi/2)$ then expectation of $\frac{\prod_{k=1}^n\tan x_k}{\sum_{k=1}^n\tan x_k}$ is $(\pi/2)^{2n-6}$ for $n>2$.

Let $E(n)=\text{expectation of }\dfrac{\prod_{k=1}^n\tan x_k}{\sum_{k=1}^n\tan x_k}$ where x_k are independent uniformly random real numbers in $\left(0,\frac{\pi}{2}\right)$. Is the following conjecture true: $E(n)=\left(\frac{\pi}{2}\right)^{2n-6}$ for $n>2$. Context Earlier I found that $E(2)=\left(\frac{2}{\pi}\right)^2\int_0^{\pi/2}\int_0^{\pi/2}\frac{(\tan x_1)(\tan x_2)}{\tan x_1+\tan x_2}dx_1dx_2=\frac{2}{\pi}$. Naturally, I wondered if $E(n)$ has closed forms for other n values. Basis of my conjecture $E(3)=\left(\frac{2}{\pi}\right)^3\int_0^{\pi/2}\int_0^{\pi/2}\int_0^{\pi/2}\frac{(\tan x_1)(\tan x_2)(\tan x_3)}{\tan x_1+\tan x_2+\tan x_3}dx_1dx_2dx_3=0.9999996\dots$, according to Desmos. I guess it's actually 1. For $n>3$, Desmos and Wolfram Cloud don't work, so I used Excel with about a million trials. I got: $E(4)\approx2.480$, whereas $\left(\frac{\pi}{2}\right)^{2(4)-6}\approx2.467$ $E(5)\approx6.047$, whereas $\left(\frac{\pi}{2}\right)^{2(5)-6}\approx6.088$ $E(6)\approx16.794$, whereas

$\left(\frac{\pi}{2}\right)^{2(6)-6}\approx15.022$ $E(7)\approx37.495$, whereas $\left(\frac{\pi}{2}\right)^{2(7)-6}\approx37.065$ As n increases, the values of $\dfrac{\prod_{k=1}^n\tan x_k}{\sum_{k=1}^n\tan x_k}$ fluctuate more and more, so this numerical approach becomes less reliable. If my conjecture is true, I can't imagine what a proof would look like.

What is the change in angle of of a symmetric matrix when summed over a plane?

A symmetric matrix has orthogonal eigenvectors with real eigenvalues, and hence can be thought of as scaling along a particular orthogonal set of axes. Of course, not all vectors are (usually) eigenvectors, and therefore many individual vectors will have their direction changed under a symmetric matrix. It seems to me, however, that these direction changes will somehow "cancel out" in the sense that there is no net rotation by a symmetric matrix. I don't know how to state this more precisely, other than to observe that $A_{ij} - A_{ji}$ is a measure of the rotation in the i,j plane (see here). That is, if A is a symmetric matrix, for any plane P, the net direction change of Av over all vectors $v \in P$ is zero. Again, I'm not sure how state this more precisely, but perhaps it could be formulated as an integral. Is my intuition correct? And how can it be stated more precisely?

Conjecture: In Pascal's triangle with n rows, the proportion of numbers less than the centre number approaches $e^{-1/\pi}$ as $n\to\infty$.

Consider Pascal's triangle with 30 rows (the top 1 is the 0th row). The centre number is the number in the middle of row $30\times \frac23=20$, which is $\binom{20}{10}=184756$. The proportion of the numbers in the triangle that are less than this centre number is $\frac{364}{496}\approx0.7339$. In the following graph, the horizontal axis is n, the number of rows in the triangle (n is a multiple of 3). The vertical axis is P, the proportion of numbers that are less than the centre number. It looks like P is approaching some limit. The rightmost data point is $n=138$ and $P=\frac{7078}{9730}\approx0.72744$. I put 0.72744 into Wolfram, and it suggested $e^{-1/\pi}\approx 0.72738$. Is the following conjecture true or false: Conjecture: In Pascal's triangle with n rows, where n is a multiple of 3, the proportion of numbers less than the centre number approaches $e^{-1/\pi}$ as $n\to\infty$. I would not be too surprised if this is in fact the limiting proportion, since e is related to Pascal's triangle and so is π. My attempt: The numbers in the top $\frac23$ of the triangle are all less than the centre number. So we just need to determine the proportion of numbers in the bottom $\frac13$ that are less than the centre number. I considered the row that is m rows below the centre number: I tried to work out the proportion of numbers in this row that are less than the centre number, to obtain an asympototic boundary curve, but I didn't succeed. Context: I was trying to approximate the median of the numbers in the first n rows of Pascal's triangle, and in my investigation I stumbled upon this possible result.

Can this be done? Split Pascal's triangle (without the 1s) with a straight line into two regions of equal sums.

Consider Pascal's triangle with n rows, without the 1s, with each number corresponding to a vertex on a pyramid of equilateral triangles, as shown below with example $n=5$. Does there exist an n such that Pascal's triangle with n rows, without the 1s, can be divided by a straight line (that does not pass through any vertex) into two regions of equal sums? For example, with $n=5$, the red line below fails to divide the triangle into two regions of equal sums: the upper-left region has a sum of 58, and the bottom-right region has a sum of 56. I have tried to do this with different size triangles, without success. It seems that it cannot be done, but I don't know how to prove it. Remarks We exclude the 1s because the triangle with the 1s has a total sum of 2^n-1, an odd number, making an equal split obviously impossible. The sums of the all the terms in the first n rows (not just one row) are given by A145654 (ignoring the initial 0): $2,8,22,52,114,240,494\dots$ I considered the partial sums of a row of Pascal's triangle, but such expressions are not simple. Taking @Jean Marie's suggestion, I've added a left-justified version of the triangle, which may be easier to use. EDIT: Posted on MO

When does the magnitude of the gradient equal the surface area of the $dxdy$ patch?

Given a surface S in $\mathbb R^3$, what is the relationship between the gradient (when S is defined as a level curve of function $F: \mathbb R^3 \to \mathbb R$) and surface area? I noticed such a relationship when examining the surface area of the saddle surface $z = x^2 - y^2$. The surface area has integrand $\sqrt{1 + 4x^2 + 4y^2}$. And, when defined as a level curve $F(x,y,z) = x^2 - y^2 - z$, we get $\|\nabla F\| = \sqrt{1 + 4x^2 + 4y^2}$. What is the relationship between surface area and the gradient? Does it hold for $\mathbb R^n$ or only $\mathbb R^3$? My (incomplete) attempt is below. Partial Solution If S is a surface defined as the level curve of $F(x,y,z)$, and $\frac {\partial F}{\partial z} = \pm 1$, then the magnitude of ∇F equals the ratio of surface area of a portion of S to its projection on the xy plane, and $$\text{Surface Area } = \iint \|\nabla F\| dx dy.$$ Given a surface S, point $v \in S$, and plane P, define surface amplification of S over P as $$\lim_{\delta \to 0} \frac{\text{surface area of }R}{\text{area of }R \text{ projected onto } P}$$ where R is a region of S including point v with area δ. (Formalizing this limit is hard.) If S is parameterized by $(x, y, Z(x,y))$, then surface amplification over the xy plane equals $$\sqrt{1 + \frac{\partial Z}{\partial x}^2 + \frac{\partial Z}{\partial y}^2}$$ as can be easily seen from the standard surface area integral. If S is defined as the level surface of $F(x,y,z)$, and $\frac {\partial F}{\partial z} = \pm 1$, then surface amplification over the xy plane equals $\| \nabla F \|$, which follows from the definition of

gradient. (How do I show this clearly?) I conjecture this applies for any $\mathbb R^n$. This post may be related. Is this correct? How do we complete the proof? What is the geometric intuition behind this?

An infinite linear system of equations with an uncountable number A of equations

I will start with an example to make things clear and avoid confusion : Take all $x>0$ and $$\exp(x) = \sum_{-1<n} a_n x^n$$ Now finding a_n can be described as an infinite linear system of equations : $$a_0 + a_1 1 + a_2 1 + ... = e$$ $$a_0 + a_1 2 + a_2 4 + ... = e^2$$ $$...$$ and for every $x>0$ $$a_0 + a_1 x + a_2 x^2 + ... = e^x$$ So we have a countable number of variables and an uncountable number of equations. Notice there is only one unique solution set a_n here. This leads to : Conjecture : An infinite linear system of equations with an uncountable number A of equations, but a countable number B of variables has at most countable ordinal C * Linear independant * solutions, where $C < B$ and Linear independant means not a COUNTABLE LINEAR combination of others. Notice that (in contrast) a countable number of (linear) equations with a countable number of variables CAN have an uncountable number of solutions, who are linear independant. For instance the (formal) taylor series solution to $f(x) = f(\exp(x))$ has an uncountable number of solutions and it is equivalent to a system of linear equations with a countable number of variables (the taylor coefficients). Explicitly: $$t_i = \sum_n \frac{t_n n^i}{n!}$$ And examples without calculus, dynamics or functional equations exist as well.

Take a random walk on Pascal's triangle, without revisits: Does the final number have infinite expectation?

Let's take a random walk on Pascal's triangle, starting at the top. Each number is in a regular hexagon. At each step, we can move to any adjacent hexagon with equal probability, but we cannot revisit a hexagon. The walk ends when we cannot move. Here is an example in which the final number is 15. Does the final number have infinite expectation? (Paradoxically, a random variable whose possible values are all finite, can have infinite expectation.) My thoughts I suspect the answer is yes, because as we move down Pascal's triangle, the numbers quickly become very large. But I don't know how this could be proved. After some step, if we find ourselves in "open territory" (no previously visited hexagons nearby), then there is a sequence of five moves that would end the walk. This is illustrated by this image provided by @Stef in the comments: (The first red line segment after the blue line segment could have been in any other direction, so we don't count that one.) The probability of such a sequence would be $\left(\frac{1}{5}\right)\left(\frac{1}{5}\right)\left(\frac{1}{5}\right)\left(\frac{1}{5}\right)\left(\frac{1}{4}\right)=\frac{1}{2500}$. Using the expectation of a geometric distribution, the expected number of steps in a walk would be roughly 2500. I believe, but am not sure, that the expected row number at the end would be on the order of $\sqrt{2500}=50$. (This rough analysis ignores several factors, for example the effect of the boundaries of the triangle.) But sometimes our walk would go much deeper than the expected depth. The numbers in the triangle increase very quickly. Generally speaking, if the numbers increase faster than the probabilities of reaching them decrease, then the expectation of the final number could be infinite. Context This is one of several questions about Pascal's triangle that I've asked recently, for example: Does the interior of Pascal's triangle contain three consecutive integers? I tried to kill the central binomial coefficients, but they came back Conjecture: In Pascal's triangle with n rows, the proportion of numbers less than the centre number approaches $e^{-1/\pi}$ as $n\to\infty$.. Sometimes I am more interested in the methods used to answer the questions, than the answers themselves (but I am still curious what the answer is!). Many of my questions initially seemed almost unapproachable to me, but then turned out to have a rational explanation.

Conjecture: $\prod\limits_{k=0}^{n}\binom{2n}{k}$ is divisible by $\prod\limits_{k=0}^n\binom{2k}{k}$ only if $n=1,2,5$.

The diagram shows Pascal's triangle down to row 10. I noticed that the product of the blue numbers is divisible by the product of the orange numbers. That is (including the bottom centre number 252 in both products), $$\frac{\prod\limits_{k=0}^{5}\binom{10}{k}}{\prod\limits_{k=0}^5\binom{2k}{k}}=\frac{2857680000}{4233600}=675\in\mathbb{Z}.$$ Now let $$P=\frac{\prod\limits_{k=0}^{n}\binom{2n}{k}}{\prod\limits_{k=0}^n\binom{2k}{k}}$$ According to Wolfram, for $n=1$ to $n=50$, P is an integer only when $n=1,2,5$. Is the following conjecture true or false: P is an integer only when $n=1,2,5$. P can be rewritten as $$P=\prod\limits_{k=0}^n\frac{(2n)!k!}{(2k)!(2n-k)!}$$ but that doesn't seem to make the question easier to answer. I did a search on the OEIS using "$1,2,5$ Pascal divisible", and found no sequence with $1,2,5$ and the next number being greater than 50. Context: I have been trying to unravel some of the mysteries of Pascal's triangle recently, for example with questions about random walks, three consecutive numbers and killing.

Conjecture: If $\sum_{i=1}^n \frac{1}{x_i}=1$ then $x_i | x_j$

Let $x_1,x_2,x_3,\cdots , x_n\in\mathbb{N}$ prove that if $\sum_{i=1}^n\frac{1}{x_i}=1$, then there exist x_j,x_i such that $x_j | x_i$. I read that I should avoid the no clue questions, but this is a conjecture I came up with and need to know if it's true to continue my work on some project. All I could figure out is that it's true for $n=2$ - and then $x_1=x_2=\frac{1}{2}$ Edit The user @deif proved the conjecture if there exist atleast one x_i which is prime. So to prove the conjecture entirely(if it's true) we just need to prove it with the assumption that $x_1,x_2,\cdots ,x_n$ are not primes!

Does this recursive journey through Pascal's triangle always reach 1?

Let $p(k)$ be the k^th number in Pascal's triangle, numbered from left to right in each row, going down the rows. So, for example, $p(1)$ to $p(10)$ are $\binom{0}{0},\space \binom{1}{0},\space \binom{1}{1},\space \binom{2}{0},\space \binom{2}{1},\space \binom{2}{2},\space \binom{3}{0},\space \binom{3}{1},\space \binom{3}{2},\space \binom{3}{3}$, respectively. Now define sequence a_n as: $$a_1\text{ is a positive integer}$$ $$a_{n+1}=p(a_n)$$ Is the following conjecture true or false: Conjecture: $\lim\limits_{n\to\infty}a_n=1$ for all $a_1\in\mathbb{Z^+}$. For example, with $a_1=150$ we have: $a_2=p(150)=560$ $a_3=p(560)=32$ $a_4=p(32)=35$ $a_5=p(35)=7$ $a_6=p(7)=1$ $a_n=1$ for $n\ge 6$ With $a_1=100$ we have: $a_2=p(100)=1287$ $a_3=p(1287)=37353738800$ $a_4=p(37353738800)=\space ?$ If an a_n value is very large, then a_{n+1} is likely to be much larger than a_n. However, even if the terms become very large, it is possible that eventually one of them will be small enough so that the sequence will become an endless stream of 1s. I don't know how the sequence will play out. Here and here is the sequence $p(k)$, except their index is shifted down 1 from mine. So for example, my $p(5)$ is numbered as the 4th term is the linked sequence. Context: I have been playing with Pascal's triangle, investigating some of its mysterious, geometrical and humourous properties.

A generalization of the Stolz-Cesàro: For $k\ge 1$, $\lim_{n\to\infty }\frac{a_{n+k}-a_n}{b_{n+k}-b_n}=l$ implies $\lim_{n\to\infty}\frac{a_n}{b_n}=l$

Stolz-Cesàro theorem case $\frac{*}{\infty}$:- If $b_n $ is a monotone increasing sequence and $\lim \limits_{n \to \infty} b_n = \infty $, and if $\lim \limits_{n \to \infty} \frac{a_{n+1}-a_n}{b_{n+1}- b_n}= l \in \overline{\mathbb{R}} $, then $\lim \limits_{n \to \infty} \frac{a_n }{b_n}=l$. Stolz-Cesàro theorem case $\frac{0}{0}$:- If $b_n $ is a monotone decreasing sequence and $\lim \limits_{n \to \infty} b_n = \lim \limits_{n \to \infty} a_n = 0 $, and if $\lim \limits_{n \to \infty} \frac{a_{n+1}-a_n}{b_{n+1}- b_n}= l \in \overline{\mathbb{R}} $, then $\lim \limits_{n \to \infty} \frac{a_n }{b_n}=l$. I was solving this limit :If $a_n \to a \in \mathbb{R}$ find $$\lim\limits_{n \to \infty } \frac{\sum\limits_{k=1}^n (-1)^{n-k} 2^k a^k}{2^n}$$ The numerator is a bit annoying to apply Stolz-Cesàro theorem to because of that $(-1)^{n-k}$. The numerator is $\sum\limits_{k=1}^n (-1)^{n-k} 2^k a^k$ when n is odd and $-\sum\limits_{k=1}^n (-1)^{n-k} 2^k a^k$ when n is even. It would have been much easier if $\lim\limits_{n \to \infty } \frac{a_{n +2}- a_n}{b_{2+n}- b_n}= l$ was true, and out of curiosity, I tried to use this statement here: $$\lim \limits_{n \to \infty} \frac{2^{n+2}a_{n+2}-2^{n+1}a_{n+1}}{2^{n+2}-2^{n}}=\lim \limits_{n \to \infty} \frac{4a_{n+2}-2a_{n+1}}{3} =\frac{2a}{3}$$ Which, in fact, is the correct limit! This got me wondering if there is a generalisation of the Stolz-Cesàro Theorem. Generalized Stolz-Cesàro theorem case $\frac{*}{\infty}$:- If $b_n $ is a monotone increasing sequence and $\lim \limits_{n \to \infty} b_n = \infty $, and $\exists k \in \mathbb{N}$ st $\lim \limits_{n \to \infty} \frac{a_{n+k}-a_n}{b_{n+k}- b_n}= l \in \overline{\mathbb{R}} $, then $\lim \limits_{n \to \infty} \frac{a_n }{b_n}=l$. Generalized Stolz-Cesàro theorem case $\frac{0}{0}$:- If $b_n $ is a monotone decreasing sequence and $\lim \limits_{n \to \infty} b_n = \lim \limits_{n \to \infty} a_n = 0 $, and if $\exists k \in \mathbb{N}$ st $\lim \limits_{n \to \infty} \frac{a_{n+k}-a_n}{b_{n+k}- b_n}= l \in \overline{\mathbb{R}} $, then $\lim \limits_{n \to \infty} \frac{a_n }{b_n}=l$. Example: $\lim_limits_{n \to \infty}\frac{(-1)^n}{n } =0$ but the ordinal Stolz-Cesàro Limit don't exist , if the generalisation was true then $\lim \limits_{n \to \infty} \frac{a_{n+2} -a_{n}}{b_{n+2}-b_{n}}= 0$ (I know this is a trivial example) If it is not true, then what are the sufficient conditions for a_n,b_n so that this generalisation of the Stolz-Cesàro theorem becomes true?

Conjecture: $\sum\limits_{k=1}^nk^m=S_3(n)\times\frac{P_{m-3}(n)}{N_m}$ for odd $m>1 \ ;\ =S_2(n)\times\frac{P_{m-2}'(n)}{N_m}$ for even m.

When I was in high school, I was fascinated by $\displaystyle\sum\limits_{k=1}^n k= \frac{n(n+1)}{2}$ so I tried to find the general solution for $\displaystyle\sum\limits_{k=1}^n k^m$ s.t $m \in \mathbb{N}$. I used a similar approach to my answer here My approach was turning n^m to $n(n-1)(n-2)\dots (n-m+1)+ f(n)$ and to use the fact that $$\displaystyle\dbinom{n}{k}+\dbinom{n}{k+1}= \dbinom{n+1}{k+1}$$ $f(n) $ will be combination of sums $\displaystyle\sum_{k=1}^n k^i$ st $i<m$ which I evaluated before I was able to to find the sum up to $m=6$. Here, I tried to search for a pattern to find the general solution of $\sum\limits_{k=1}^n k^m $ s.t $m \in \mathbb{N}$ which I failed to do, but I noticed this pattern: $\\[3pt]$ $$S_1(n):={\sum\limits_{k=1}^n k= \frac{n(n+1)}{2}}$$ $$S_2(n):={\sum\limits_{k=1}^n k^2= \color{blue}{\frac{n(2n+1)(n+1)}{6}}}$$ $$S_3(n):={\sum\limits_{k=1}^n k^3= \color{red}{\frac{\color{red}{n^2(n+1)^2}}{\color{red}{4}}}}$$ $$S_4(n):={\sum\limits_{k=1}^n k^4=\color{blue}{\frac{n(2n+1)(n+1)}{6}} \times \frac{3n^2+3n-1}{ 5}}$$ $$S_5(n):={\sum\limits_{k=1}^n k^5= \color{red}{\frac{\color{red}{n^2(n+1)^2}}{\color{red}{4}}} \times\frac{2n^2+2n-1}{ 3}}$$ $$S_6(n):={\sum\limits_{k=1}^n k^6= \color{blue}{\frac{n(2n+1)(n+1)}{6}} \times \frac{3n^4+6n^3-3n+1}{ 7 }}$$ $$S_7(n):={\sum\limits_{k=1}^n k^7= \color{red}{\frac{\color{red}{n^2(n+1)^2}}{\color{red}{4}} }\times\frac{3n^4+6n^3-n^2-4n+2}{ 6}}$$ $$S_8(n):={\sum\limits_{k=1}^n k^8= \color{blue}{\frac{n(2n+1)(n+1)}{6}} \times \frac{5n^6+15n^5+5n^4-15n^3-n^2+9n+3}{ 15}}$$ $$S_9(n):={\sum\limits_{k=1}^n k^9= \color{red}{\frac{\color{red}{n^2(n+1)^2}}{\color{red}{4}}} \times\frac{(n^2+n-1)(2n^4 +4n^3-n^3-3n^2+3)}{ 5}}$$ $$S_{10}(n):={\sum\limits_{k=1}^n k^{10}= \color{blue}{\frac{n(2n+1)(n+1)}{6}} \times \frac{ 3 n^8+ 12 n^7+ 8 n^6 - 18 n^5- 10 n^4+ 24 n^3 + 2 n^2 - 15 n +5}{ 11}}$$ $$S_{11}(n):={\sum\limits_{k=1}^n k^{11}=

\color{red}{\frac{\color{red}{n^2(n+1)^2}}{\color{red}{4}}} \times\frac{2n^8 +8n^7+4n^6-16n^5-5n^4+26n^3-3n^2-20n+10}{ 6}}$$ $\\[6pt]$ I noticed that: For odd $m>1$, $\displaystyle\sum\limits_{k=1}^n k^m= \color{red}{\frac{{n^2(n+1)^2}}{{4}}} \times \frac{P_{m-3}(n)}{N_m}$ s.t $P_{m-3}(n)$ is an $m-3$ polynomial with integer coefficients $ \{a_{m-3},\dots a_1,a_0 \}$ such that $\gcd \{ a_{m-3},\dots a_1,a_0 \}=1$, $N_m\in \mathbb {N}$. For even m, $\displaystyle\sum\limits_{k=1}^n k^m= \color{blue}{\frac{n(2n+1)(n+1)}{6}}\times \frac{P_{m-2}'(n)}{N_m}$ s.t $P_{m-2}'(n)$ is an $m-2$ polynomial with integer coefficients $\{ a_{m-2},\dots a_1,a_0 \}$ such that $\gcd \{ a_{m-2},\dots a_1,a_0 \}=1$, $N_m\in \mathbb {N}$. When I was in high school I couldn't prove this pattern, and this question reminded me of this observation that I had totally forgotten about. Now, after two years from my first attempt, I tried to prove this pattern again, but I couldn't. EDIT This question has been partly answered in this MathOverflow answer (The answer shows that $\displaystyle\sum\limits_{k=1}^n k^m$ is divisible by ${n^2(n+1)^2}$ for odd $m>1$ and $\displaystyle\sum\limits_{k=1}^n k^m$ is divisible by ${n(2n+1)(n+1)}$ for even m) the only missing part is to show that the denominator is a multiple of 4 if $m\in 2\mathbb{N}+1$, and the denominator is a multiple of 6 if $m \in 2\mathbb{N}$. Although this question has been almost solved before, I still would like to see if there is any other proofs or methods. Update: I asked this question on MO here

Does $\int_{1}^{2}\ln\left(x+\ln\left(x^2+\ln\left(x^3+\ln\left(\dots\right)\right)\right)\right)dx=1$?

I was messing around with the infinitely nested logarithm $f(x)=\ln\left(x+\ln\left(x^2+\ln\left(x^3+\ln\left(\dots\right)\right)\right)\right)$ on Desmos when I decided to take the integral from $x = 1$ to $x = 2$. Here's what I got where n represents the number of times the logarithm is nested. For example, for $n=1$, it is $f_1(x)=\ln\left(x\right)$ and for $n=2$, it is $f_2(x)=\ln\left(x+\ln\left(x^2\right)\right)$. $$\begin{array}{c|c} \text{n} & \int_{1}^{2}{f_n(x)}dx \\ \hline 1 & 0.38629436112 \\ \hline 2 & 0.769701324476 \\ \hline 3 & 0.923253197047 \\ \hline 4 & 0.968765188969 \\ \hline 5 & 0.982950647903 \\ \hline 10 & 0.992710069039 \\ \end{array}$$ $\therefore\text{I conjecture that it converges to 1}$ Can someone help me analytically prove or refute my conjecture? I lack the skills to do it. P.S. I could not figure out a closed form for the infinitely nested logarithm but I assume finding one would make this a lot easier to prove.

Conjecture about boundary commuting with union

Given a Topological space (X,τ) and two disjoint open sets A,B, the following holds: $$\partial(A\cup B) = \partial A\cup \partial B$$ I am interested in a modified version of this. Construction: Let $\mathcal{R}$ be the collection of rays (one dimensional subspaces) of $\mathbb{R}^2$. We call a subset of $\mathbb{R}^2$ an open stick, if it is bounded, connected, contains $(0,0)$, is contained in some $r\in \mathcal{R}$, and is open in the subspace Topology of this r. Here is your typical stick (Desmos doesn't do open dots at the ends for some reason): Now suppose we have some stick family (s_r) indexed by $\mathcal{R}$. Also, for each stick s_r, denote by $\partial's_r$ its boundary in the subspace r. Question: When is it possible to conclude $$ \partial \bigcup_{r\in \mathcal{R}} s_r = \bigcup_{r\in \mathcal{R}}\partial' s_r \hspace{ 0.5cm } ?$$ I conjecture that it is precisely when $ \bigcup_{r\in \mathcal{R}}\partial' s_r \simeq S^1$, the unit circle! The intuition for this is rather simple, for this identity to hold, we need each stick to contribute only its endpoint to the boundary of the union, and to prevent a stick from contributing a point other than its endpoint, we need to ensure that there is no discontinuity in the length of the sticks, at that particular stick. But I am looking for help to turn this into a rigorous argument.

Conjecture: $\binom{n}{k } \mod m =0$ for all $k=1,2,3,\dots,n-1$ only when $m $ is a prime number and n is a power of m

While playing with Pascal's triangle, I observed that $\binom{4}{k } \mod 2 =0$ for $k=1,2,3$,and $\binom{8}{k } \mod 2 =0$ for $k=1,2,3,4,5,6,7$ This made me curious about the values of $n>1$ and $m>1$ that satisfy $\binom{n}{k } \mod m =0$ for all $k=1,2,3,\dots,n-1$ I asked my friend to write a $C++$ code that could test this condition for n up to 10000 and m up to 31 and I found out that $\binom{n}{k } \mod m =0$ for all $k=1,2,3,\dots,n-1$ only when $m $ is a prime number and n is a power of m. #include <bits/stdc++.h> using namespace std;` typedef long long ll; #define rep(i , st , ed) for(int i = st; i < ed; i++) #define f first #define s second const int N = 10000; const int mod = 31; ll nCr[N][N] , frq[N]; void gen(){ nCr[0][0] = 1; for (int i = 0; i < N; ++i) { nCr[i][0] = nCr[i][i] = 1; for (int j = 1; j < i; ++j) { nCr[i][j] = (nCr[i-1][j] + nCr[i-1][j-1]) % mod; if(nCr[i][j] == 0) frq[i]++; } } } ll get(int n , int r){ return (n >= r) ? nCr[n][r] : 0; } int main(){ ios::sync_with_stdio(0); cin.tie(NULL); cout.tie(0); gen(); for(int i = 1; i < N; ++i) if(frq[i] == i - 1){ cout << i << '\n'; } } After many attempts to prove or disprove this conjecture, I couldn’t find a solution. This statement is the same as $$\gcd\left(\binom{n}{1 }, \binom{n}{2 },\dots , \binom{n}{n-1 } \right)= \begin{cases} p, & \text{if n is a power of a prime p} \\[2ex] 1, & \text{else. } \end{cases}$$

Conjecture: If A,B,C are random points on a sphere, then $E\left(\frac{\text{Area}_{\triangle ABC}}{\text{Area}_{\bigcirc ABC}}\right)=\frac14$.

On (not in) a sphere, choose three independent uniformly random points A,B,C. Is the following conjecture true: The expectation of the ratio of the area of (planar) $\triangle ABC$ to the area of the (planar) disk with A,B,C on its perimeter, is $1/4$. My conjecture is based on experimentation: using sphere point picking, I ran 1.5×10^7 trials and the average ratio was about 0.2500075. Since $1/4$ is a simple ratio, I am wondering if there is an intuitive explanation (here is a recent example), but any proof is welcome. Remarks: Assume the sphere is a unit sphere. The expected area of the disk is $\frac{4\pi}{5}$ (proof). The expected area of the triangle seems to be $\frac{\pi}{5}$ based on experimentation, but I don't have a proof (Wolfram has a page called "Sphere triangle picking" but it's empty). Curiously, the expectation of the ratio seems to equal the ratio of the expectations. The probability that the ratio is greater than $1/4$ is about 0.534. The standard deviation of the ratio is about 0.10667 (could it be $8/75$?). The probability density function of the ratio looks roughly like this: The expectation of the reciprocal ratio (i.e. the ratio of the area of the disk to the area of the triangle) seems to be about 6.6, but this ratio flucuates a lot and I'm not sure its expectation even exists. My attempt: I tried to adopt the techniques in the proof that the area of the disk is $\frac{4\pi}{5}$ (with a unit sphere), but I don't know how to express the area of the triangle in a usable way. I tried to find a more intuitive explanation, possibly using symmetry, but failed. (In the $2D$ case, the expected ratio of areas is $\frac{3}{2\pi^2}\approx 0.15198$ (proof), which is not an intuition-friendly number, so it seems that an intuitive explanation would apply to the $3D$ case but not the $2D$ case.) Context: This question was inspired by a question about a random triangle inscribed in a circle.

Values of $\Phi_n(-1)$

Let $$\Phi_n(x) = \prod_{0<k\leq n, \gcd(k,n)=1}(x-e^{\frac{2\pi i k}{n}})$$ be the n-th cyclotomic polynomial. By observation it seems that cyclotomic polynomials when evaluated at $x=-1$ give the following $$\Phi_n(-1) = \begin{cases} 2 \quad \text{if} \quad n = 2^k, k>1\in \mathbb{N}\\ p \quad \text{if} \quad n = 2p\\ 1 \quad \text{otherwise} \end{cases}$$ where p denotes a prime (> 2). The first few cases are $$\Phi_1(-1) = -2$$ $$\Phi_2(-1) = 0$$ $$\Phi_3(-1) = 1$$ $$\Phi_4(-1) = 2$$ $$\Phi_5(-1) = 1$$ $$\Phi_6(-1) = 3$$ $$\Phi_7(-1) = 1$$ $$\Phi_8(-1) = 2$$ however we will only consider $n>2$ for the conjecture. This I thought was quite weird at first as it seems like a very simple pattern for something as complicated as the coefficients of cyclotomic polynomials. I managed to prove the first two cases, and will share the short proofs below, but am unsure of how to tackle the last case. I don't have any way to check for high values of n other than calculation, and so I apologise in advance if there is a counterexample to this conjecture that can easily be checked with a computer. Below are the proofs for $n= 2^k$ and $n=2p$, $n = 2^k$ By Möbius inversion we get $$\Phi_n(x) = \prod_{d\mid n}(x^d-1)^{\mu\left(\frac{n}{d}\right)}$$ Since $\mu(2^n) = 0$ for $n>1$ with $\mu(2)=-1$, therefore $$\Phi_{2^n}(x) = (x^{2^n}-1)(x^{2^{n-1}}-1)^{-1} = x^{2^{n-1}}+1$$ $$\Phi_{2^n}(-1) = 2$$ $n = 2p$ We can use the following identity $$\Phi_{2p}(x) = \sum_{k=0}^{p-1}(-1)^kx^k$$ $$ = \sum_{k=0}^{p-1}1 = p$$ But for the 'otherwise' case, I don't know how to approach it. It seems to general to approach in any specific way using identities or by looking at the values of $\mu(d)$ as that would require more information about the divisors of n. Any help or a proof/counterexample is appreciated!

Moments of Alternate Elliptic Integrals

Let K_s denote Ramanujan's Alternate Elliptic Integrals as follows: $$K_s:=K_s(k)=\frac{\cos(\pi s)}{2}\int_0^1\frac{t^{s-1/2}}{(1-t)^{1/2+s}(1-k^2t)^{1/2-s}}dt$$ Where in Hypergeometric Form it is: $$K_s=\frac{\pi}{2}{}_2F_1\left[\frac{1}{2}+s,\frac{1}{2}-s,1,k^2\right]$$ The following signatures are important in this theory: $$s=\left\{0,\frac{1}{3},\frac{1}{4},\frac{1}{6}\right\}$$ I have found a General Theorem to calculate the following Integral: $$\int_0^1kK_uK_vdk$$ As examples I will present the corollaries that follow from the Theorem while considering the combination of 4 signatures. This gives us the following 10 Integrals: Corollaries: $$\int_0^1kK^2dk=\frac{7\zeta(3)}{4}$$ $$\int_0^1kK^2_{1/6}dk=\frac{9\sqrt{3}}{8}\operatorname{Cl_2}(\pi/3)$$ $$\int_0^1kK^2_{1/3}dk=\frac{15\sqrt{3}}{16}\operatorname{Cl_2}(\pi/3)$$ $$\int_0^1kK^2_{1/4}dk=2\beta(2)$$ $$\int_0^1kKK_{1/6}dk=\frac{27\sqrt{3}}{4}\ln 3-9\sqrt{3}\ln 2$$ $$\int_0^1kKK_{1/3}dk=\frac{27}{16}\ln 3$$ $$\int_0^1kKK_{1/4}dk=2\sqrt{2}\ln 2$$ $$\int_0^1kK_{1/3}K_{1/6}dk=\frac{3\sqrt{3}}{2}\ln 2$$ $$\int_0^1kK_{1/4}K_{1/6}dk=\frac{27\sqrt{6}}{5}\ln 2-\frac{27\sqrt{6}}{10}\ln3$$ $$\int_0^1kK_{1/4}K_{1/3}dk=\frac{27\sqrt{2}}{14}\ln 3-\frac{9\sqrt{2}}{7}\ln 2$$ The very first Integral is known in this list as K_0 is just the Complete Elliptic Integral of the First Kind K. I have not seen the General Theorem and Other Integrals as well anywhere in Literature. So I was wondering whether these results are new or already known? This is only a Small List, one may produce as many Integrals as they want from the General Theorem. Like for example after Differentiating: $$\int_0^1kK\left[\frac{d}{dv}K_v\right]_{v=1/4}dk=2\sqrt{2}\left(8\beta(2)-\pi \ln2-8\ln 2\right)$$ This opens up new possibilities too. The following is for example already known: $$\int_0^1k^{2n+1}K^2dk=a_n\zeta(3)+b_n$$ where $a_n,b_n\in\mathbb{Q}$. This is found using "FindIntegerNullVector": Conjecture: $$\int_0^1k^{2n+1}K^2_{1/6}dk=a_n\sqrt{3}\operatorname{Cl_2}(\pi/3)+b_n$$ $$\int_0^1k^{2n+1}K^2_{1/3}dk=a_n\sqrt{3}\operatorname{Cl_2}(\pi/3)+b_n$$ $$\int_0^1k^{2n+1}K^2_{1/4}dk=a_n\beta(2)+b_n$$

$$\int_0^1k^{2n+1}KK_{1/3}dk=a_n\ln 3+b_n$$ where $a_n,b_n\in\mathbb{Q}$. The rest of the cases doesn't seem to continue the pattern. I wonder if there is any greater meaning behind this: $$\left[\begin{array}{c} \text{Integral}&\text{Basis} \\\\ \displaystyle\int_0^1k^{2n+1}K_0^2dk&\zeta(3)\\\\ \displaystyle\int_0^1k^{2n+1}K_{1/6}^2dk&\sqrt{3}\operatorname{Cl_2}(\pi/3)\\\\ \displaystyle\int_0^1k^{2n+1}K_{1/3}^2dk&\sqrt{3}\operatorname{Cl_2}(\pi/3)\\\\ \displaystyle\int_0^1k^{2n+1}K_{1/4}^2dk&\beta(2)\\\\ \displaystyle\int_0^1k^{2n+1}K_0K_{1/3}dk&\ln3\\\\ \end{array} \right]$$

Conjecture about average cluster size in a prime-like sequence

Consider the sequence $u_n=n^a+p_n$, where a is a real constant and p_n is the nth prime. Write down the terms in u_n increasing from left to right. From each term, draw a line segment connecting it to its numerically closer neighbor, choosing the lower in case of a tie, thus forming clusters. Here is an example with $a=1$. $\color{red}{3-5-8-11} \qquad \color{blue}{16-19} \qquad \color{brown}{24-27-32} \qquad \color{green}{39-42}\qquad \color{orange}{49-54-57-62-69} \qquad \color{purple}{76-79} \qquad \cdots$ The cluster sizes are $4,2,3,2,5,3,\dots$. Is the following conjecture true: Conjecture: The average cluster size is 3 if $a\le 2$, and infinity if $a>2$. My conjecture is based on numerical investigation with Excel, using the first 10^6 primes. My conjecture can be expressed more precisely as follows. For a given value of a, let $f(a,c)$ be the arithmetic mean of the sizes of the first c clusters. My conjecture is that, as $c\to\infty$, $f(a,c)$ approaches 3 if $a\le 2$, and $f(a,c)$ approaches infinity if $a>2$. Connection with Poisson distribution In a $1D$ Poisson process, the probability that a point is its nearest neighbor's nearest neighbor, is $p=2/3$, as shown here, so the average cluster size is $2/p=3$, as shown here. Coming back to this question, I guess that u_n resembles a $1D$ Poisson process in some critical way if $a\le 2$. This question was inspired by the question linked to above.

Three random points on $x^2+y^2=1$ are the vertices of a triangle. Is the probability that $(0,0)$ is inside the triangle's incircle exactly 0.13?

Three uniformly random points on the circle $x^2+y^2=1$ are the vertices of a triangle. What is the probability that $(0,0)$ is inside the triangle's incircle? (This a variation of the question "What is the probability that $(0,0)$ is inside the triangle?".) A simulation with 10^8 trials gives $P\approx 0.129963$. Is the probability exactly 0.13? If so, this would be the weirdest geometrical probability I have ever seen. My attempt: Let $d=$ distance between the circles' centres, and let $r=$ radius of the triangle's incircle. We are looking for $P(d<r)$. Euler's triangle formula tells us that $d=\sqrt{1-2r}$. So we are looking for $P(\sqrt{1-2r}<r)=P(r>\sqrt2-1)$. I do not know how to calculate this probability. I know that $r=\sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$ where a,b,c are the side lengths of the triangle and $s=\frac{a+b+c}{2}$.

Conjecture: Expected total area of a certain set of random triangles in a unit disk is $1/\pi$.

Choose $3n$ independent uniformly random points in a disk with perimeter $x^2+y^2=1$. Label the points $P_1,P_2,P_3,\dots,P_{3n}$ in order of increasing x-coordinates. Form triangles $\triangle P_1P_2P_3,\space \triangle P_4P_5P_6,\space \dots,\space \triangle P_{3n-2}P_{3n-1}P_{3n}$. Here is an example with $3n=21$. What does the total area of the triangles approach as $n\to\infty$? I did a simulation of 100 trials with $3n=99999$, and the average total area was 0.318343178. This number multiplied by π is approximately 1.00010, so I conjecture that the answer is $1/\pi$. My attempt I considered a simpler related question: What is the expected area of a triangle with vertices $(1,a_1),(2,a_2),(3,a_3)$ where the a values are independent uniformly random real numbers in $[0,1]$? The probability that a_2 is between a_1 and a_3 is $1/3$. We have $\mathbb{E}(\max (a_1,a_2,a_3)-\min (a_1,a_2,a_3))=\frac12$ (explanation). The left and right sub-triangles share a vertical side, which in this case has expected length $\frac18$. So the expected area of the triangle is $2\times\frac12\times\frac18\times 1=\frac18$. The probability that a_2 is not between a_1 and a_3 is $2/3$. Again we have $\mathbb{E}(\max (a_1,a_2,a_3)-\min (a_1,a_2,a_3))=\frac12$. The left and right sub-triangles share a vertical side, which in this case has expected length $\frac38$. So the expected area of the triangle is $2\times\frac12\times\frac38\times 1=\frac38$. So the overall expected area of the triangle is $\frac13\times\frac18+\frac23\times\frac38=\frac{7}{24}$. This value is supported by a simulation. In the original question, the triangles are not limited to a rectangular box of height 1, but rather are limited to a unit disk, which has an average height of $2\int_0^1\sqrt{1-x^2}\mathrm dx=\frac{\pi}{2}$. The rectangle and the disk have the same width, but in the disk there are horizontal gaps between neighboring triangles, so we multiply by a factor of $\frac23$. So the total area of the triangles in the disk should approach approximately $\frac{7}{24}\times\frac{\pi}{2}\times\frac23=\frac{7\pi}{72}\approx 0.30543$. This is slightly less than $\frac{1}{\pi}\approx 0.31831$. The difference may be due to the fact that the x-coordinates of the points in the disk do not have equal spacing. EDIT: I made a mistake in my simulation. Using the shoelace theorem, the area of the triangle with vertices $(x_1,y_1),(x_2,y_2),(x_3,y_3)$ is $\frac12|x_1y_2-x_2y_1+x_2y_3-x_3y_2-x_1y_3+x_3y_1|$, but I was accidentally using $\frac12|x_1y_2-x_2y_1+x_2y_3-x_3y_2-x_1y_3+x_\color{red}{1}y_1|$. After correcting, my simulations suggest the answer is approximately 0.320, which agrees with @Rei Henigman's answer. So I no longer think my conjecture is true, but I would still like to know if the limiting area of the triangles has a closed form. I also did a (correct) simulation using a square lamina instead of a disk, and it seems that the proportion covered by the triangles is about 0.102, which seems to match the proportion in the disk. Context This question was inspired by the question "A disc contains n random points. Each point is connected to its

nearest neighbor. What does the average cluster size approach as $n\to\infty$?".

New conjecture? $(\varphi(n))! = -1 \pmod n \iff n$ is prime (nearly the same as Wilson's)

$$ (n-1)! = -1 \pmod n \text{ iff } n \text{ is prime}, \text{ is Wilson's theorem,} $$ But coincidentally for now the expression passed to factorial is $n - 1$ which is (iff n is prime) equal to $\varphi(n)$. So, I was thinking, don't we have this related conjecture: $$ \varphi(n)! = -1 \pmod n \text{ iff } n \text{ is prime} $$ Because the following example verification code seems to indicate as such: from sympy import * N = 10000 for n in range(2, N): r = factorial(totient(n)) % n if isprime(n): assert (r + 1) % n == 0 else: assert (r + 1) % n != 0 print(n, r) Which prints: 2 1 3 2 4 2 5 4 6 2 7 6 8 0 9 0 10 4 11 10 12 0 13 12 14 6 15 0 16 0 17 16 18 0 19 18 20 0 21 0 22 10 23 22 24 0 25 0 26 12 27 0 28 0 29 28 30 0 31 30 32 0 33 0 34 16 35 0 36 0 37 36 38 18 39 0 40 0 41 40 42 0 43 42 44 0 45 Conjecture: For any prime n, at least one of $2n^2-1$, $2n^2+1$, or $\sqrt{2n^2-1}$ is prime.

In my spare time, I came up with this conjecture: For any prime n, at least one of $2n^2-1$, $2n^2+1$, or $\sqrt{2n^2-1}$ is prime. Examples: \begin{alignat}{2} 2 &\to\quad 2\cdot 2^2-1 &&\quad=7 \\ 3 &\to\quad 2\cdot 3^2-1 &&\quad=17 \\ 5 &\to\quad \sqrt{2\cdot 5^2-1} &&\quad=7 \\ 7 &\to\quad 2\cdot 7^2-1 &&\quad=97 \\ 11 &\to\quad 2\cdot 11^2-1 &&\quad=241 \\ 13 &\to\quad 2\cdot 13^2-1 &&\quad=337 \\ 17 &\to\quad 2\cdot 17^2-1 &&\quad=577 \end{alignat} Can somebody prove this?

True or false: In a 2D Poisson process, for every point P, there exists a convex 1000-gon with Poisson points as vertices, that contains only P.

I made a Desmos graph that generates 30 uniformly random black points in a disk, with the centre of the disk in red. I asked myself, "Can I always draw a convex quadrilateral with four of the random points as vertices, such that its interior contains the centre of the disk but does not contain any of the random points?" The answer seems to be yes, based on experimentation. Then I asked myself the same question, except with "quadrilateral" replaced by pentagon, hexagon, or heptagon, and the answer still seems to be always yes. So my question is: True or false: In a 2D Poisson process, for every point P, there exists a convex 1000-gon with Poisson points as vertices, whose interior contains P and none of the other random points. I suspect the answer is yes. By making the polygon very long and narrow, maybe we can always find enough points to serve as vertices. But I'm not sure if this is true. Context: Recently I have been investigating inherent properties of the $2D$ Poisson process, for example here, here and here.

A conjecture on representing $\sum\limits_{k=0} ^m (-1)^ka^{m-k}b^k$ as sum of powers of $(a+b)$.

UPATE: I asked this question on MO here. I was solving problem 1.2.52 in "An introduction to the theory of numbers by by Ivan Niven, Herbert S. Zuckerman, Hugh L. Montgomery" Show that if $\gcd(a, b)$ = 1 and p is an odd prime, then $\displaystyle \gcd\left(a+b, \frac{a^p+b^p}{a+b}\right)=1$ or p. So I tried to represent $\displaystyle \sum_{k=0} ^m (-1)^ka^{m-k}b^k$ as sum of powers of $a+b$ For any even number m that is one less than a prime number . $$\sum_{k=0} ^2 (-1)^k a^{2-k}b^k = (a+b)^2 -3ab$$ $$\sum_{k=0} ^4 (-1)^k a^{4-k}b^k = (a+b)^4 -5(ab)(a+b)^2 +5(ab)^2$$ $$\sum_{k=0} ^6 (-1)^k a^{6-k}b^k = (a+b)^6 -7(ab)(a+b)^4 +7 \cdot 2(ab)^2(a+b)^2 -7(ab)^3$$ I noticed that $\displaystyle \sum_{k=0} ^m (-1)^ka^{m-k}b^k=(a+b)^m +(m+1)\left(\sum_{k=1}^{\frac m 2} g_m(k)(-(ab))^k (a+b)^{m-2k}\right)$ where $g_m(k): \mathbb{N} \to \mathbb{Z}$ (I was not able to find a way to determine of $g_m(k)$) I couldn't prove this pattern or find $g_m(k)$ or prove that $\displaystyle \sum_{k=0} ^2 (-1)^k a^{2-k}b^k $ can be represented as sum of powers of $a+b$ For any even number m that is one less than a prime number. So my question is: How to prove that for any $m=p-1$ such that p is prime number $\displaystyle \sum_{k=0} ^m (-1)^ka^{m-k}b^k=(a+b)^m +(m+1)\left(\sum_{k=1}^{\frac m 2} g_m(k)(-(ab))^k (a+b)^{m-2k}\right)$ and determine $g_m(k)$. I don't think it is possible represent $\displaystyle \sum_{k=0} ^m (-1)^ka^{m-k}b^k$ in the form $\displaystyle(a+b)^m +(m+1)\left(\sum_{k=1}^{\frac m 2} g_m(k)(-(ab))^k (a+b)^{m-2k}\right)$. I don't think this will work for any even number because I noticed that in any even rows m that is above a prime row p i.e ($p=m+1$) in this image There is a very interesting property $\dbinom{m}{k}+(-1)^{k+1} |p $ for example $253+1|11 , \ \ 15-1 | 7$ and so on but for any other even row this doesn't hold.

On the fractional parts of the roots of the Alternating Harmonic Numbers

We define $$\bar{H}_x=\ln2+\cos(\pi x)\left(\psi(x)-\psi\left(\frac x2\right)-\frac1x-\ln2\right)$$As the xth Alternating Harmonic Number (test out a few values to see why). Let x_n be the nth largest zero of the Alternating Harmonic Numbers, show that $\lim_{n\rightarrow\infty}\{x_n\}=\eta$ converges (where $\{x\}$ denotes the fractional part of x) or equivalently

$\lim_{n\rightarrow\infty}(x_n-x_{n+1})=1$. This definition of the alternating harmonic number originates from my terribly formatted paper where I generalize sigma notation for non-integer upper and lower bounds. Graphically speaking, the conjecture (I called it so in my paper because I couldn't solve it) seems to be true and $\eta\approx-0.431$. Some interesting approximations are $\frac{7\pi}{51}$ and this seemingly random integral $$\int_0^1\frac{\bar{H}_x\bar{H}_{-x}\sin(\pi x)}{\pi x}dx\approx0.43141591$$Not only does it hold for three digits, but there is a decimal representation of pi mixed in, up to 5 accurate decimal digits. Anyway, using the reflection formula derived for $\bar{H}_x$: $$\bar{H}_x-\bar{H}_{2-x}=\pi\cot(\pi x)-\left(\frac1{1-x}+\frac1x-\frac1{2-x}\right)\cos(\pi x)$$ we get that the conjecture is equivalent to finding the limit of the fractional part of the roots of $$\bar{H}_x-\bar{H}_{2-x}+\ln2=\ln2+\pi\cot(\pi x)-\left(\frac1{1-x}+\frac1x-\frac1{2-x}\right)\cos(\pi x)$$I got stuck here.

(dis)proof of conjecture on square unit fractions

Consider a finite set S of positive integers, and define $q(S) = \sum_{s \in S}{1/s^2}$. Letting $\rho = \pi^2/6$, we have $q(S)$ in the ranges $[0, \rho - 1), [1, \rho)$. I conjecture that for every rational r within those ranges, $\exists S: q(S) = r$. Can anyone prove or disprove this? Note that for plain unit fractions $u(S) = \sum_{s \in S}{1/s}$ it is straightforward to show by a greedy algorithm that $\exists S: u(S) = r \forall r \in \mathbb{Q}^+$; conversely for prime unit fractions $p(S) = \sum_{s \in S}{1/p_s}$ almost all rationals are unreachable, since for each S, $p(S)$ has a unique (squarefree) denominator. Given that the primes are denser than the squares, it would thus be a somewhat interesting result if the conjecture were to be proven. Computationally I have established existence of S for all rationals with denominators up to 50 within the range; see results on github. Update: added "finite" to clarify first sentence; corrected $\mathbb{R}$ to $\mathbb{Q}$.

For any square-free $n \geq 1$ and $a \in \Bbb{Z}/n$ including $\gcd(a,n) \neq 1$, then in the list $a, a^2, a^3, \dots$ either a or a^2 repeats?

For example, modulo 30 we have that $\gcd(5, 30) = 5$, but $5, 5^2, 5^3 = 5, 5^2, \dots$ goes the list, so both repeat. We know it's true when $\gcd(a,n) = 1$ because a cyclic group is formed in $\Bbb{Z}/n^{\times}$, s it's sufficient to prove the case when $\gcd(a, n) = d \neq 1$. Another example: $$ n = 15:\\ 3, 3^2, 3^3=-3,-3^2,(-3)^2=3^2, \dots \\ 6,6,6, \dots \\ 9,9^2=6,9, \dots\\ 5,10,5,10, \dots\\ $$ Is this hopelessly difficult to prove?

Are there infinitely many primes that are a highly composite number ± 1?

I've looked at some highly composite numbers and realized that a lot of them are almost primes, i.e. differ only by 1 to the next closest prime. Here's a short list (I made) of highly composite numbers and whether they are almost prime: $$ 1 \text{, true $(+1)$} \\ 2 \text{, true $(+1)$} \\ 4 \text{, true (± 1)} \\ 6 \text{, true (± 1)} \\ 12 \text{, true (± 1)} \\ 24 \text{, true (-1)} \\ 36 \text{, true $(+1)$} \\ 48 \text{, true (-1)} \\ 60 \text{, true (± 1)} \\ 120 \text{, false} \\ 180 \text{, true (± 1)} \\ 240 \text{, true (± 1)} \\ \dots $$ I've thought about it, and it's actually not so surprising that many highly composite numbers (which I've checked) are almost prime. Since $n \pm 1$ won't share any prime divisors with n, it's likely for $n \pm 1$ to be prime if n has a high number of divisors. But are there infinitely many highly composite numbers that are ± 1 a prime? I don't know how I would prove something like this-I'm not even sure if this conjecture really holds. Also, if there are infinitely many such numbers, do they get rarer? And at what rate?

Conjecture about Proving Primality of Fermat numbers by Elliptic Curves technic

In 2008 and 2009, Denomme-Savin and Tsumura provided 2 papers providing a Primality Test for Fermat numbers based on Elliptic Curves technic: $$ \text{Let } DST(x)= \frac{\displaystyle x^4+2x^2+1}{\displaystyle 4(x^3-x)} \ \text{ and } \ F_n = 2^{2^n}+1 $$ $$ \text{Let } x_1=F_1=\pm 5, \ x_{j+1} = DST(x_j)$$ $$ \text{If } x_{2^{n-1}} \equiv \mp 1 \pmod{F_n} \ , \ \text{then } F_n \text{ is prime.}$$ Now, can you prove the following conjecture (which makes use of a BigTree of the DiGraph): $$\text{Let } x_1 = \pm 4 \ , \ x_{j+1} = DST(x_j) $$ $$\text{If } x_{2^{n-1}} \equiv 0 \pmod{F_n} \ , \ \text{then } F_n \text{ is prime}.$$ And, then, can you prove the following conjecture (which makes use of a Cycle of the DiGraph): $$\text{Let } x_1 = \pm 1/3 \ , \ x_{j+1} = DST(x_j) $$ $$\text{If } x_{2^{n}-1} \equiv x_1 \pmod{F_n} \ , \ \text{then } F_n \text{ is prime}.$$ R. Denomme and G. Savin, “Elliptic curve primality tests for fermat and related primes,” Journal of Number Theory, vol. 128, no. 1, pp. 2398-2412, 2008. Y. Tsumura, “Elliptic curve primality tests for fermat and related primes” 2009.

An extension of Brahmagupta's theorem.

As we know, there are conjectures that are easy to formulate but difficult to prove, and there are conjectures that are easy to prove but difficult to conceive. This conjecture is simple to conceive and probably has a simple proof, however I could not find any reference to it on the Internet so I quote it here: In the image below, the cyclic crossed quadrilateral A, B, C, D is orthodiagonal, in the sense that the lines passing through the vertices A, C and B, D intersect each other perpendicularly at a point M outside the circle. Prove that the perpendicular to a

side from the point M always bisects the opposite side (the intersecting sides AD and BC are considered opposite each other). Brahmagupta's theorem: https://en.m.wikipedia.org/wiki/Brahmagupta_theorem In Geogebra, the transition from Brahmagupta's theorem to the above conjecture is done naturally by moving the yellow control point in and out of the circle, respectively: https://www.geogebra.org/m/wthe5qt2

Is $N=3\cdot 2^k+1$ prime if and only if $2^{N-1}\equiv 1 \pmod N$?

Is the following statement true? Let $k\geq 1$ be an integer and $N=3\cdot 2^k+1$. Then N is a prime prime if and only if $2^{N-1}\equiv 1 \pmod {N}$ One implication is simply a Fermat's Little Theorem, so the difficult part is proving or disproving that $2^{N-1}\equiv 1 \pmod {N}$ implies N is a prime. Or in other words showing whether there is a k such that N is a Fermat pseudoprime to base 2 (Poulet Number). I have checked the claim holds for $k\leq 15000$. As for the proof, we know complete factorization of $N-1$ so I was thinking of Lucas primality test, for which it would be sufficient to show that if $2^{N-1}\equiv 1 \pmod {N}$, then $2^{\frac{N-1}{3}}\not\equiv 1 \pmod {N}$ and $2^{\frac{N-1}{2}}\not\equiv 1 \pmod {N}$. Then I thought about Poclikngton primality test, but it requires a prime $p\mid N-1$ with $p>\sqrt{N}-1$ which we don't have (as $p=2,3$). As noted by Peter in comments, the last requirement can be removed in which case it's sufficient to prove $\gcd(2^{\frac{N-1}{3}}-1,N)=\gcd(2^{\frac{N-1}{2}}-1,N)=1$, however that seems stronger than what suffices for Lucas' test. I don't expect this result to be anything new or profound, I just have not found/proven it yet... Then again, I am not way too familiar with primality tests. As from where this comes from, I just did a computer search to look for similar criterion as Lucas-Lehmer test but for numbers of form $3\cdot 2^k+1$ and it found a match which when solving the recurrence to a closed form gave the statement above.

If $\lim\limits_{x\to\infty}\frac{f(x+1)-f(x)}{g(x+1)-g(x)}=l$ what are sufficient conditions to make $\lim\limits_{x\to\infty}\frac{f(x)}{g(x)}=l$?

In this question it is proved in the answers that If $f :[0 , \infty) \to \mathbb{R}$ and $f $ is bounded on every (a,b) such that $a<b <\infty$, prove that $\lim\limits_{x \to \infty }(f(x+1) - f(x))=l$ implies $\lim\limits_{x \to \infty }\frac{f(x)}{x}=l$. This condition looks suspiciously similar to Stolz-Cesaro theorem see this for a proof of using Stolz-Cesaro theorem . My question is : If If $f,g :[0 , \infty) \to \mathbb{R}$ $\lim\limits_{x\to\infty}\frac{f(x+1)-f(x)}{g(x+1)-g(x)}=l$ what are sufficient conditions for f,g to make $\lim\limits_{x\to\infty}\frac{f(x)}{g(x)}=l$? Of course when f and $g $ are both differentiable functions on $\mathbb{R}$ and if $\lim\limits_{x \to \infty } g(x)= \infty$ this condition sufficient to make $\lim\limits_{x\to\infty}\frac{f(x)}{g(x)}=l$, but this hypothesis is too strong is there a weaker hypothesis. and I want to generalise this result. I conjectured this more general hypothesis : If f is bounded on every (a,b) such that $a<b <\infty$, g is a continuous increasing function on $\mathbb{R}$ then $\lim\limits_{x\to\infty}\frac{f(x)}{g(x)}=l$. I couldn't prove this result but I think it is true. My question is this conjecture true ? If it was true is there a weaker hypothesis ? If it wasn't true, Is there a weaker hypothesis than f and $g $ are both differentiable functions on $\mathbb{R}$ and]$\lim\limits_{x \to \infty } g(x)= \infty$?

Closed form for this generalisation of the gamma function. $f(x+1)=f(x)g(x+1) $

Just for curiosity I want to generalise the Pi function i.e $f(x+1) = f(x)g(x+1)$ for some differentiable function, I know this function probably has no closed form for general functions g as I couldn't find any but maybe it exist and more experienced user can find it. For a differentiable function g on $\mathbb{R}^+$ and $\exists M \in \mathbb{R}$ st $\forall x>M$ $g(x)\ge0$ with $g(1)\ne 0$ define $f(x+1) = f(x)g(x+1)$ To make it clear that f depends on x and g I will write it as $\Pi(x, g(t))$, $\Pi(x, t)$ is just the ordinary pi function. . I found analogous result to the Gauss product by a non rigorous approach. $$\Pi(x, g(t)) = \lim_{n \to \infty } g(n)^x \prod\limits_{1\le k\le n} \frac{g(k)}{g(k+x)} $$ With this It is easy to see that $\Pi(x, t^a) =\Pi(x, t)^a $, $\Pi(x, e^t)=1 $. As I said before, probably there is not a closed form for a general function g put if a closed form could be found when g is any polynomial satisfying the conditions of g this could be extended to power series which cover a wide range of functions.

How do you find constants in an k-Tuple conjectures?

By introducing modular objects associated to the sequel of rings $$(Z/2,Z/6,Z/30,Z/210,Z/2310,..., Z/p_n\#Z)$$ a sequence of coefficients is updated$$(2;\color{green}{\frac83}; 3.2;...$$ (see my answer to my proper question here) I've been running computers and I've observed that There are twice more primes p such that $p+6$ is also prime (sexys) than twins; $\color{green}{\frac83}$ more primes p such that $p+30$ is also prime than twins; 3.2 more p such that $p+210$ is also prime than twins; ... Until now, I had always had the greatest difficulty in deciphering how to find these constants in Wolphram Alpha's article about k-Tuples conjectures. For example, for $p+$30, where I'm looking for $\color{green}{\frac83}$, I understand that I am interested in what the article notes $$\boxed{C(15)=2\prod_{q\text{ prime}}^{}\frac{q(q-2)}{(q-1)^2}\prod_{q|15}^{}\frac{q-1}{q-2}}$$ In fact, the initial purpose of my post was even to ask for help to do so but I think I'm starting to understand since $$\prod_{q|15}^{}\frac{q-1}{q-2}=\frac{3-1}{3-2}\frac{5-1}{5-2}=2\times\frac{4}{3}=\color{green}{\frac{8}{3}}$$ 1.- I still have to think about it a little more, maybe get your help but it will do it. 2.- But, suddenly, a more interesting question arises for me: is this approach in modular arithmetic to highlight the Hardy and Littlewood coefficients, but

especially to give them a non-statistical modular meaning (see here) , known? Definitions, notations and examples: $p_1=2, p_2=3, p_3=5, p_4=7, p_5=11, ... , $ are the primes; $\forall n\in \mathbb N^*, p_n\#:=p_1\times p_2\times ....\times p_n$; examples : $p_1\#=2, p_2\#=p_1\times p_2=2\times 3=6, p_3\#=2.3.5=30, ...$

Conjecture: Two different random triangles (both based on random points on a circle) have the same distribution of side length ratios.

On a circle, choose three uniformly random points A,B,C. Triangle T_1 has vertices A,B,C. The side lengths of T_1 are, in random order, a,b,c. Triangle T_2 is formed by drawing tangents to the circle at A,B,C. (T_2 may or may not lie inside the circle.) The side lengths of T_2 are, in random order, d,e,f. Is the following conjecture true: The distribution of ratios of a,b,c is the same as the distribution of ratios of d,e,f. So for example, if my conjecture is true, then we would have the following probability equations: $P(a^2+b^2<c^2)=P(d^2+e^2<f^2)$ $P(a^3+b^3<c^3)=P(d^3+e^3<f^3)$ $P(ab<c^2)=P(de<f^2)$ $P\left(\frac1a+\frac1b<\frac1c\right)=P\left(\frac1d+\frac1e<\frac1f\right)$ (My conjecture, if true, would not imply that $P(ab<c)=P(de<f)$, because these inequalities are not dimensionally homogeneous.) Basis for my conjecture I found that $P(ab<c^2)=\frac35$. Then I wondered what $P(de<f^2)$ equals, and a simulation suggests that it also equals $\frac35$. I found that $P\left(\frac1a+\frac1b<\frac1c\right)=\frac15$. Then I wondered what $P\left(\frac1d+\frac1e<\frac1f\right)$ equals, and a simulation suggests that it also equals $\frac15$. I tried some other probabilities, and simulations suggest that each probability has the same value for the two triangles. So I suspect that the two triangles have the same distribution of ratios of side lengths. But I don't know why.

Consecutive numbers

Are there ever more consecutive composite numbers than there are primes up to that point? I imagine not, because the primes are the ones which cancel out multiples, so will inevitably have to fill in the gaps between multiples of them. Then again, the number of combinations possible grows faster than an exponential. It may be a matter of calculating how many products are within certain bounds. Additionally, I have that there is a known set of composite numbers, an infinite union of sets described by an arithmetic sequence. $\{9+6x\}\cup\{15+10x\}\cup\{21+14x\}\cup\{33+22x\}\cup\{39+26x\}\cup...$ which when removed from the odd numbers yields the prime numbers. Conversely, if we show that there is a point that many of these terms are lining up with common difference 2 we have shown some progress on the result.

What is the $\inf$ and $\sup$ of the area of quadrilateral given its sides length?

Now asked on MO here. Given the length of the sides of a quadrilateral a,b,c,d the area of the quadrilateral is less than or equal to $\frac{(a+b+c+d)^2}{16}$ i.e it is an upper bound of the area of any quadrilateral with side length a,b,c,d. A question that came to my mind is if $\frac{(a+b+c+d)^2}{16}$ is an upper bound Then the least upper bound exits so what is the infimum and supremum of the area of quadrilateral (0 is an oblivious lower bound so the infimum exists too)? I made a silly mistake thinking that $\frac{(a+b+c+d)^2}{16}$ is the supremum but it turns out I was wrong. If $a=b, \ c=d$ "a kite" or if $a=c, \ d=b$ "a parallelogram" then it is easy to prove the infimum is 0 and the supremum is just a^2 when it is a rhombus. The infimum depends on a,b,c,d in this examples the side lengths are $19,13,7,4$ and the minimum area is around 9.5 so it is not 0. Conjecture: If $a<b<c<d$ and the area of the quadrilateral is S then $\inf S $ is the area of the triangle $a,b,d-c$ which is $$\sqrt{\frac{a+b+d-c}{2}\cdot\frac{a-b+d-c}{2}\cdot\frac{-a+b+d-c}{2}\cdot\frac{a+b-d+c}{2}}$$ This also works when $a=b=c=d, \ \ \ a=b, \ c=d \ \ \ ,a=c, \ d=b $. I couldn't rigorously proof that claim but I am pretty sure it is correct. In the previous example when side lengths are $19,13,7,4$ the naximum area is around 73.5 but this time I have no Idea what kind of shape is that. How to determine the infimum and the supremum of the area given a,b,c,d.

The vertices of a hexagon are random points on a unit circle; a,b,c are the lengths of three random sides. Conjecture: $P(ab<c)=\frac35$.

The vertices of a hexagon are uniformly random points on a unit circle; a,b,c are the lengths of three distinct random sides. A simulation with 10^7 such random hexagons yielded a proportion of 0.60008 of them satisfying $ab<c$. Is the following conjecture true: $P(ab<c)=\dfrac35$. Probabilities involving the side lengths of random polygons inscribed in a circle are often simple rational numbers; for example here, here and here. Those examples involve triangles, which are determined by only two parameters (two random central angles, with the third angle determined by the others), so it was easy to set up an integral. But this question involves a hexagon, which involves five parameters (five random angles, with the sixth angle determined by the others), and I do not know how to set up an integral. Sometimes these kinds of questions can be answered without integration, using pure geometry, for example here. But I have been unable to find a purely geometric proof for this question. $P(ab<c)$ seems to be a simple rational number only for triangles and hexagons, among n-gons for $3\le n\le 12$, based on simulations. Distribution of a Here I derive $f(x)$, the density function of a, which is the same as the density function of b and c. However, I do not know if this is helpful, because a,b,c are not independent. Suppose the first chosen random point on the circle is O, and a is the length of the side immediately anticlockwise from O. $a>x$ if all the other chosen points are on the major

arc subtended by the red line segment, and the other chosen points are not all on the minor arc subtended by the green line segment. $\theta=\arcsin \frac{x}{2}$ $\begin{align} P(a<x)&=1-P(a>x)\\ &=1-\left(\left(1-\frac{1}{\pi}\arcsin\frac{x}{2}\right)^5-\left(\frac{1}{\pi}\arcsin\frac{x}{2}\right)^5\right) \end{align}$ $\begin{align} f(x)&=\frac{d}{dx}P(a<x)\\ &=\frac{5}{\pi\sqrt{4-x^2}}\left(\left(1-\frac{1}{\pi}\arcsin\frac{x}{2}\right)^4+\left(\frac{1}{\pi}\arcsin\frac{x}{2}\right)^4\right)\\ \end{align}$ I checked that $\int_0^2f(x)\mathrm dx=1$.

The vertices of a pentagram are five random points on a circle. Conjecture: The probability that the pentagram contains the circle's centre is $3/8$.

The vertices of a pentagram are five uniformly random points on a circle. Is the following conjecture true: The probability that the pentagram contains the circle's centre is $\frac38$. (The pentagram is said to contain the circle's centre if the central pentagon, or any of the five triangles adjecent to the central pentagon, contains the circle's centre.) A simulation with 10^7 such random pentagrams yielded a proportion of $0.3750079\approx1.00002\times\frac38$ containing the circle's centre. Thus, my conjecture. How to set up a simulation Let the circle be $x^2+y^2=1$ with centre $O\space(0,0)$. Assume the first random point is $(1,0)$ and let the other four random points be, going anticlockwise from $(1,0)$: $(\cos\theta_1,\sin\theta_1)$, $(\cos\theta_2,\sin\theta_2)$, $(\cos\theta_3,\sin\theta_3)$, $(\cos\theta_4,\sin\theta_4)$. Let A,B,C,D,E be the five regions in the circle and outside the pentagram, going anticlockwise starting with the region between $(1,0)$ and $(\cos\theta_1,\sin\theta_1)$. O lies in A if and only if $\theta_2>\pi,$ and $\theta_4-\theta_1<\pi$. O lies in B if and only if $\theta_2>\pi,$ and $\theta_3-\theta_1>\pi$. O lies in C if and only if $\theta_3-\theta_1>\pi$, and $\theta_4-\theta_2>\pi$. O lies in D if and only if $\theta_3<\pi,$ and $\theta_4-\theta_2>\pi$. O lies in E if and only if $\theta_3<\pi,$ and $\theta_4-\theta_1<\pi$. The pentagram contains O just if O lies in none of A,B,C,D,E. If my conjecture is true, then, given the simplicity of the probability, there might be a proof based on some kind of symmetry.

What is $\sup\{a\}$ such that for continuous non differentiable function f $\lim\limits_{h\to0}\frac{f(x+h)-f(x)}{h^a}$ exist?

Now asked on MO here The definition of the derivative of a function f at a point x is : $\lim\limits_{h \to 0 }\frac{f(x+h) -f(x)}{h}$ but what if we change that h to be any continuous function $g(h)$ that goes to 0 as h goes to 0? Lets focus our attention at powers of h so $g(h)=h^a$ for some a. If f is a differentiable function at x any function other than h the absolute value of the derivative will go to either 0 or ∞. I will refer to $\lim\limits_{h \to 0 }\frac{f(x+h) -f(x)}{g(h)}$ as $a-$derivative. A question that came to my mind Given any continuous function nowhere differentiable on $\mathbb{R}$ is there a g such that the absolute value of the $a-$derivative" exist almost everywhere and how to determine such functions ? The case where $g(x)$ is big enough to make this $a-$derivative 0 is annoying because one can say a very big number like $a=1/TREE(3) $ and say, for example, at this number the $a-$derivative exist and it is 0 for the Weierstrass function, so let me clear that : Given any continuous function nowhere differentiable what is the $\sup g(x)$ such that $\lim\limits_{h \to 0 }\frac{f(x+h) -f(x)}{g(h)}= 0$ for all x where the $\sup $ is taken of all real a does the absolute value of the $a-$derivative exist at that value ? Lets take L. van der Waerden's function for example Define $g(x)= |x|$ for $|x|\in [-1,1]$, $g(x+2)=g(x)$ $$f(x)= \sum_{n \ge 1} \frac{3^n g\left(4^n x\right) }{4^n}$$ Is an example of continuous function nowhere differentiable, There is a proof that the absolute value secant line's slope goes to infinity as it approaches the point so this made me wonder will the absolute value of the $a-$derivative exist if we decrease the power of h?

A probability involving side lengths of a random triangle on a disk: Is it really $\frac37$?

Choose three uniformly random points on a disk, and let them be the vertices of a triangle. Call the side lengths, in random order, a,b,c. What is $P(a^2<bc)$? A simulation with 10^7 such random triangles yielded a proportion of $0.4285833\approx1.00003\times\frac{3}{7}$ satisfying $a^2<bc$, leading me to believe that the probability is $\frac37$. I find this alleged probability interesting because it seems that the number 7 rarely appears in the answers to natural geometry or probability questions. Context Recently I have learned that some probabilities related to circles, of the form $P(x^2<yz)$, have simple rational values (for example, a probability about a random triangle inscribed in a circle, and a probability about a random pentagram inscribed in a circle). So I wondered if there is a probability like this related to a disk. I may have found one. My attempt Let the boundary of the disk be $x^2+y^2=1$. Using disk point picking, let the three points be $C\left(\sqrt{r_1}\cos\theta_1,\sqrt{r_1}\sin\theta_1\right)$ $B\left(\sqrt{r_2}\cos\theta_2,\sqrt{r_2}\sin\theta_2\right)$ $A\left(\sqrt{r_3},0\right)$ where each r is a uniformly random real number from 0 to 1, and each θ is a uniformly random real number from 0 to 2π. Let $a=BC$, $b=AC$, $c=AB$. This gives: $$P(a^2<bc)=P\left(r_1+r_2-2\sqrt{r_1r_2}\cos(\theta_1-\theta_2)<\sqrt{\left(r_1-2\sqrt{r_1r_3}\cos\theta_1+r_3\right)\left(r_2-2\sqrt{r_2r_3}\cos\theta_2+r_3\right)}\right)$$ I do not know how to set up an integral, nor any other way to calculate the probability. Apparently, after the dust settles, we should be left with $\frac37$.

For any positive integer $n\geq5$, there is at least one integer $m>n$ such that $ \pi\left(nm\right)=n+m $

Conjecture: For any positive integer $n\geq5$, there is at least one integer $m>n$ such that $ \pi\left(nm\right)=n+m $, where $\pi\left(x\right)$ is the prime counting function. Examples: $$ \pi(5\times9)=5+9=14 $$ $$ \pi(6\times7)=6+7=13 $$ $$ \pi(7\times368)=7+368=375 $$ $$ \pi(8\times998)=8+998=1006 $$ $$ \pi(9\times2551)=9+2551=2560 $$ I'm looking for either a proof of the conjecture, or at least an heuristic argument for big enough n. Computations: The nbr column denotes the number of solutions, while the min and max columns represent the first and last solutions. n nbr min max 1 0 2 0 3 0 4 0 5 22 9 41 6 9 7 148 7 14 368 409 8 1 998 998 9 12 2551 2597 10 6 6331 6424 11 7 15866 15889 12 25 39860 39970 13 20 100135 100192 14 9 251616 251637 15 19 636787 637063 16 2 1617099 1617110 17 13 4124188 4124272 18 9 10553076 10553278 19 13 27066256 27066824 20 28 69709243 69709557 21 17 179992154 179992524 22 50 465769460 465769748 23 13 1208198239 1208198402 24 43 3140421185 3140421406 25 20 8179001679 8179001739 26 8 21338684878 21338685037 27 68 55762147707 55762148901 28 1 145935688930 145935688930 29 95 382465571795 382465572544 Graph: Here is a graph of $\pi(nm)-(n+m)$ for $n=12$: And here is the same graph, but zoomed on the interval where it crosses the 0 axis: In this example, $n=12$, the line touches 25 times the 0 axis, and we can expect that as n gets bigger, the interval in which the line is close to 0 will also become larger.

A continuous nowhere differentiable function with $\alpha-$derivative exists at $\sup\{a\}$.

In This question I asked: Define $g(x)= |x|$ for $|x|\in [-1,1]$, $g(x+2)=g(x)$ $$f(x)= \sum_{n \ge 1} \frac{3^n g\left(4^n x\right) }{4^n}$$ what is the $\sup \{\alpha\}$ such that $$ \lim\limits_{h \to 0 }\frac{f(x+h) -f(x)}{h^\alpha}= 0 $$ for all x? Does the absolute value of the $\alpha-$derivative exist at that value of α ? I expected that the absolute value of the $\alpha -$derivative exist at the $\sup \{\alpha\}$ but it turns out I was wrong as this answers shows (the supremum is $\frac{\ln\left(\frac 4 3\right)}{\ln 4}$ btw) . My question is: Is there a continuous nowhere differentiable function with the $\alpha-$derivative exist at that value of $\sup \{\alpha\}$ where is the sup is taken on all reals such that $ \lim\limits_{h \to 0 }\frac{f(x+h) -f(x)}{h^\alpha}= 0 $ for all x? If it is impossible to have such function how to prove that?

Conjectured connection between e and π in a semidisk.

A semidisk with diameter $\dfrac{e}{\pi}n$ is divided into n regions of equal area by line segments from a diameter endpoint. Here is an example with $n=6$. Consider the n arcs between neighboring line segment endpoints. Let $P(n)=\text{product of arc lengths}$. Is the following conjecture true: Conjecture: $\lim\limits_{n\to\infty}P(n)=\dfrac{\pi}{2}$ In other words, if the average arc length is $\color{red}{\dfrac{e}{2}}$ then the product of arc lengths approaches $\color{red}{\dfrac{\pi}{2}}$. Evidence for my conjecture I got the following approximations. $P(1)\approx 1.359$ $P(2)\approx 1.438$ $P(3)\approx 1.469$ $P(6)\approx 1.507$ $P(12)\approx 1.528$ $P(24)\approx 1.543$ $P(48)\approx 1.552$ $P(96)\approx 1.558$ It seems that if the average arc length is less than $\dfrac{e}{2}$ then the product approaches 0, and if the average arc length is greater than $\dfrac{e}{2}$ then the product approaches ∞. What makes this difficult What makes my conjecture difficult for me to prove or disprove, is that I cannot find exact expressions for the arc lengths. For example, in the example shown above with $n=6$, the length of the longest arc is $\dfrac{3ex}{\pi}$ where $x-\sin x=\frac{\pi}{6}$. I am aware of Kepler's equation, but that doesn't seem to help. Related questions This question is essentially the converse of my question, "Product of areas in a disk". I asked about the product of another kind of arc length related to a circle, in my question, "Another interesting property of $y=2^{n-1}\prod_{k=0}^n \left(x-\cos{\frac{k\pi}{n}}\right)$: product of arc lengths converges, but to what?". I recently asked a related question, "Product of lengths in a disk of area π/e".

Convergence of sequences formed by orthocenters, incenters, and centroids in repeated triangle constructions

Now asked on MO here. Given a scalene triangle $A_1B_1C_1$, construct a triangle $A_{n+1}B_{n+1}C_{n+1}$ from the triangle $A_nB_nC_n$ where A_{n+1} is the orthocenter of $A_nB_nC_n$, B_{n+1} is the incenter of $A_nB_nC_n$ and C_{n+1} is the centroid of $A_nB_nC_n$, My question is If this process is repeated indefinitely would the sequences $\{A_n\}$, $\{B_n\}$, $\{C_n\} $ converge ? There are only four possible scenarios: The points will converge to a point. The points will eventually stuck on a loop. The points will completely diverge. The points will eventually make an isosceles triangle (or equilateral triangle) which will end the sequence. All of these scenarios would depend on the initial triangle. So given $\angle A_1$, $\angle B_1$, $\angle C_1, $ how to determine which of the four scenario would happen to the sequences $\{A_n\}$, $\{B_n\}$, $\{C_n\} $? I tried to draw the first few triangles and see if the point will converge or not. Graphing the first 25 triangles suggests that the sequence converge. Here is the graphing the first 30 triangle, If anyone needs them. If this is true that the three sequences will converge to a point this point will be unique to the triangle, I wonder what extra properties this point have. It seems that the limit point (assuming it exists) in not in the Encyclopedia of Triangle Centers, the distance between $A_{25} $ and $\overline {B_1C_1}$ (in the triangle 6-9-13) is

0.5360763749467, the distance between $B_{25} $ and $\overline {B_1C_1}$ is 0.5360798890437 and the distance between $C_{25} $ and $\overline {B_1C_1}$ is 0.5360789119326 so the distance between limit point and $\overline {B_1C_1}$ is around 0.53607

Graph isomorphism checking/detection for directed acyclic graphs

The graph isomorphism problem is hard for an arbitrary graph, and certain classes of graphs have been proven to be "GI-complete", which as I understand means they can be reformulated in terms of a polynomial number of dual problems which themselves take polynomial time to solve. From wikipedia: In computational complexity theory, a polynomial-time reduction is a method for solving one problem using another. One shows that if a hypothetical subroutine solving the second problem exists, then the first problem can be solved by transforming or reducing it to inputs for the second problem and calling the subroutine one or more times. If both the time required to transform the first problem to the second, and the number of times the subroutine is called is polynomial, then the first problem is polynomial-time reducible to the second. I am wondering about direct acyclic graphs (a.k.a. feed-forward neural networks) specifically not because I have a research interest in them but because I happen to be confronted with them while studying the NEAT algorithm (video: video), which is a genetic/evolutionary algorithm that searches the space of different neural network architectures to find the "fittest" one for a particular task. The NEAT algorithm owes its success to the efficient way in which this exploration takes place: by uniquely labelling each edge (essentially keeping a bijective map in storage mapping a number, the "innovation number", to each possible edge) the algorithm ensures we don't create the "same" graph a second time. There is also this other thing called speciation, which is a measure of how different two graphs are based on the number of extra edges one graph has compared to another, the number of edges that appear in exactly one and not two of the graphs, and the average edge weight difference taken over all shared edges in the two graphs. But it seems that the NEAT algorithm does not address the possibility of graphs being isomorphic. Speciation looks at the "genomes" of the two graphs. BTW computer scientists use biology vocabulary, but: gene: edge gene: edge encoding (of the form [innovation number, (v1, v2), enabled_bool, edge_weight]) node gene: similar but node info genome: set of genes. Encodes a network. Any network produced by neat should have a unique genome phenotype: the actual graph (or network) produced by the genome Just wanted to get that out of the way. So, genomes are the thing that's used to manipulate candidate networks, and the measure of how different two graphs are is a function of their genomes. But my concern is that you could have two graphs that look very similar but with completely different genomes, or two genomes that are close with respect to the speciation formula, but whose phenotypes that are completely different. The type II error here would be to have very similar graphs (topologically speaking) but with a large speciation difference measure, leading to wasted compute resources. This may seem trivial, and I will look like an idiot if someone posts a small 3 node counter example in a comment, but if one wants to check that two DAGs (directed acyclic graphs) are not isomorphic isn't it enough to do the following: (Let $d^{(v)}_{in}$ and $d^{(v)}_{out}$ be the in-degree and out-degree of a given node v.) For each graph compute the set $\{(d^{(v)}_{in},d^{(v)}_{out})\ \ |\ \ v\in V\}$. If the two sets are the same then the graphs are isomorphic, and if they are not the same, the graphs are not isomorphic. I tried some examples by hand and it really seems like this degree-pairs set criterion is plausible.

Is there a function ϕ such that $\int_0^t\int_0^t \phi(u,v) dudv=\int_0^t\psi(s)ds$?

Let t be a positive real number and ψ a positive function. I am looking for a function ϕ such that: $$\int_0^t \int_0^t \phi(u,v) du\,dv=\int_0^t\psi(s)ds$$ Does such a function exist or not?

Application of Bertrand's postulate

We can use Bertrand's Conjecture (that for any integer $n \not= 0$, there exists at least one prime number p with $n < p \leq 2n$) to demonstrate the following proposition: $\forall n \in \mathbb{N}\setminus\left\{0\right\}$, the rational number such that: $$ H_{2n} = \sum_{k = 1}^{2n}\frac{1}{k}\quad \mbox{is}\ \underline{never}\ \mbox{an integer} $$ What is the demonstration ?.

is there a function ϕ such that $\int_R \int_R f(t)g(s)\phi(t,s)dsdt=\int_Rf(t)g(t)\rho(t)dt $?

Let ρ be a positive function, is there exist a function ϕ such that for any f,g: $$\int_R \int_R f(t)g(s)\phi(t,s)dsdt=\int_Rf(t)g(t)\rho(t)dt $$ of course both integrals are supposed finite here.

Weaker than $X^2 + 1$ conjecture: $(a + bX)^2 + 1$ is a prime number at least once for any $\gcd(a,b) = 1$.

Let $\gcd(a,b) = 1$ where $a, b\in \Bbb{Z}$ and consider $f(X) = X^2 + 1$ and the forward image of the coset $a + b\Bbb{Z}$ under f. There is always at least one prime number in $f(a + b\Bbb{Z})$. Can we prove this using elementary methods?

These constrained alternating series always satisfy an inequality.

Let $x_0 \in \Bbb{N}$ and suppose that $x_1 \lt \frac{x_0}{2}$, while $0 = x_n \leq \dots \leq x_3 \leq x_2\leq x_1$. Then is it possible that: $$ \sum_{i = 0}^n (-1)^i x_i \gt 1 $$ no matter what choices are made for $x_1, \dots x_{n-1}$ in $[0, \dots, \frac{x_0}{2}) \cap \Bbb{N}$? Note that keeping the variables $x_i \in \Bbb{N}$ instead of $\Bbb{R}$ has the advantage of having only a finite number of cases to check for each $x_0 \in \Bbb{N}$. For example: $$ x_0= 4, x_1 = 1, x_2=1, x_3=1, x_4 = 0 \\ 4 - 1 + 1 -1 + 0 = 3 \gt 1 \\ 4 - 1 + 1 - 0 + 0 = 4 \gt 1 \\ 4 - 1 + 0 - 0 + 0 = 3 \gt 1 \\ 4 - 0 + 0 - 0+0 = 4 \gt 1 \\ $$ And the reason we could start at 1 on the next term is because 1 is the largest integer $\lt \frac{4}{2} = 2$. Those are all the cases to check for $x_0 = 4$. [U+1F913] I'm wondering if in general this conjecture is true.

Constructing a Curve from a Differentiable Function's Normal Lines at a Fixed Distance.

I've been experimenting with a graphing calculator and stumbled upon an interesting geometric construction involving functions and their normal lines. Here's the problem I'm trying to solve: Let's consider a differentiable function $ f$ defined on a closed interval. For a given positive real number $ r > 0 $, we perform the following construction for every point $ (x, f(x)) $ on the graph of $ f $: List item Draw the normal line to the graph of $ f $ at the point $ (x, f(x)) $. From the points on this normal line, select the one that is a distance $ r $ away from $ (x, f(x)) $ and has a $ y $-coordinate greater than $ f(x) $. If there are two such points with equal $ y $-coordinates, choose the one with the smaller $ x $-coordinate. The result of this process is a new curve, which I'll denote as $ F $. This curve is not necessarily a function. For instance, consider the function $ f(x) = (x-1)(x+2)(2x-1) $ with $ r = 0.1 $. The resulting curve from the above mapping is shown below: Additionally, here's an animation showing the function $ f(x) = (x-1)(x+2)(2x-1) $ with $ r $ varying between $ 0 $ and $ 2 $, and the corresponding curve $ F $: My question is: How can we mathematically determine the curve $ F $ given the function $ f $ and the distance $ r $? This problem appears to be quite challenging, especially for ugly functions like the antiderivative of the Weierstrass function. Any insights or methods to approach this would be greatly appreciated.

Implications of having access to the Busy Beaver oracle

Apologies if I'm asking a naïve question as I've only recently learned about the concept. What would be the practical implications (if any) of having access to a magical black box providing the values of $\Sigma(n)$? Of course, this would readily imply access to the "answers" to long-standing open problems in math, but without proofs those probably wouldn't be particularly influential. So could we make any use at all of such an oracle? A follow-up question: Is there any relation between the values of $\Sigma(n)$ for different n which could allow one to check whether the oracle is providing self-consistent outputs?

Finding measurable subsets of any given value?

I'm not sure if the following is true, but I would hope it is with the regularity properties of μ. Let X be a locally compact Hausdorff space with μ a nonzero Radon measure on X. Then given any $\alpha \in (0,\mu(X))$, there exists measurable $E \subset X$ with $\mu(E)=\alpha$. My idea was to define something like $\Lambda = \{A \subset X \: | \: \text{A measurable and $\mu(A) \leq \alpha$}\}$ and try to use sequences in Λ or even Zorn's lemma to get such a thing (Zorn's lemma seems harder to use as measurability only plays nice with countable unions). However I'm kind of stumped on how to actually go about showing this. I know that for $X = \mathbb{R}$ and $\mu=m$, you can do this trivially.

A conjecture about the sum of Faulhaber polynomials mod 2.

Context: In this question I asked about "Finding a polynomial function for alternating m numbers of odds and even numbers in sequences" I noticed that all Faulhaber polynomials are solutions for f_2 where $f_m(x)$ is apolynomial where $f_m(x)$ is odd for the first m natural numbers and $f_m(x)$ is even for the second m natural numbers and so on that made me do some experiments with $\sum\limits_{1\le k\le n} P_k(x)$. Let $P_n(x)$ be the $n-th$ Faulhaber polynomial let $Q_n(x)= \sum\limits_{1\le k\le n} P_k(x)$ let $r(n)\in \{0,1,2,3,\dots\}$ be the biggest number such that $\frac{Q_n(x)}{2^{r(n)}}$ is always integer when x is a natural number Now define $S_n(x)= \frac{Q_n(x)}{2^{r(n)}}$. I noticed that $S_n(x)$ when $x\in \mathbb{N}$ always result on a block of E even numbers followed by a block of O odd numbers. for example $S_1(x)=\frac{x(x+1)}{2}$ when $x \in \mathbb{N}$ the sequence would be the following $1,3,6,10,15,21,28,36$ so $E=O=2$ (i.e 2 evens followed by 2 odds and the cycle continue) The question is how to determine E,O for any S_n? Here is a table containing the first twelve of S_n (This is not a matrix): $\begin{bmatrix} & \text{Even(E)} &\text{Odd (O)} \\S_{1} & 2& 2 \\ S_{2}& 3 &1 \\ S_{3}& 2&2 \\ S_{4}& 4&4 \\ S_{5}& 2&2 \\ S_{6}& 3&1 \\ S_{7}& 2&2 \\ S_{8}& 4&4 \\ S_{9}& 2&2 \\ S_{10}& 3&1 \\ S_{11}& 2&2 \\ S_{12}& 4&4 \end{bmatrix}$ It seems that S_n will have a cycle $(2,2), \ (4,4), \ (2,2), \ (3,1)$ But I couldn't prove or disprove this, where (E,O) determine how many numbers even numbers and odd numbers appear in each cycle respectfully. It is easy to prove that for odd n, $(E,O)=(2,2)$ and $r(n)=0$. Also $r_{2n}=1$ for all even numbers that I tried, for some reason r_{2n} can't be greater than 1. Here is the first twelve Faulhaber polynomials: $$P_{1}(x)= \frac{x(x+1)}{2}$$ $$P_{2}(x)= \frac{x(2x+1)(x+1)}{6}$$ $$P_{3}(x)= \frac{x^2(x+1)^2}{4}$$ $$P_{4}(x)=\frac{x(2x+1)(x+1)}{6} \times \frac{3x^2+3x-1}{ 5}$$ $$P_{5}(x)= \frac{x^2(x+1)^2}{4} \times\frac{2x^2+2x-1}{ 3}$$ $$P_{6}(x)= \frac{x(2x+1)(x+1)}{6} \times \frac{3x^4+6x^3-3x+1}{ 7 }$$ $$P_{7}(x)= \frac{x^2(x+1)^2}{4 }\times\frac{3x^4+6x^3-x^2-4x+2}{ 6}$$ $$P_{8}(x)= \frac{x(2x+1)(x+1)}{6} \times \frac{5x^6+15x^5+5x^4-15x^3-x^2+9x-3}{ 15}$$ $$P_{9}(x)= \frac{x^2(x+1)^2}{4} \times\frac{(x^2+x-1)(2x^4 +4x^3-x^2-3x+3)}{ 5}$$ $$P_{10}(x)= \frac{x(2x+1)(x+1)}{6} \times \frac{ 3 x^8+ 12 x^7+ 8 x^6 - 18 x^5- 10 x^4+ 24 x^3 + 2 x^2 - 15 x +5}{ 11}$$ $$P_{11}(x)= \frac{x^2(x+1)^2}{4} \times\frac{2x^8 +8x^7+4x^6-16x^5-5x^4+26x^3-3x^2-20x+10}{ 6}$$ $$P_{12}(x)=\frac{x^{13}}{13}+\frac{x^{12}}{12}+x^{11}-\frac{11}{6}x^9+\frac{22x^7}{7}-\frac{33x^5}{10}+\frac{5x^3}{3}-\frac{961x}{2730}$$

Does the Sequence formed by Intersecting Angle Bisector in a Pentagon converges?

Now asked on MO here. Given a non-regular pentagon $A_1B_1C_1D_1E_1$ with no two adjacent angle having a sum of 360 degrees, from the pentagon $A_nB_nC_nD_nE_n$ construct the pentagon $A_{n+1}B_{n+1}C_{n+1}D_{n+1}E_{n+1}$ as follows: A_{n+1} is the intersection between the angle bisector of $\angle C_n $ and $\angle D_n$. B_{n+1} is the intersection between the angle bisectors of $\angle D_n$ and $\angle E_n$. C_{n+1} is the intersection between the angle bisectors of $\angle E_n$ and $\angle A_n$. D_{n+1} is the intersection between the angle bisectors of $\angle A_n$ and $\angle B_n$. E_{n+1} is the intersection between the angle bisectors of $\angle B_n$ and $\angle C_n$. (the two opposite angles) The reason why I chose this construction is that the point A_{n+1} is the only point that doesn't depend on A_n. I am allowing self-intersecting polygons in this constructions. My question is if this process is repeated indefinitely would the sequences ${A_n}$, ${B_n}$, ${C_n}$, $D_n $ and E_n converge ? There are only four possible scenarios: The points will converge. The points will eventually trapped on a loop. The points will diverge completely. Two or more points coincide, or two adjacent angle have a sum of 360 degrees ending the sequence. I tried to draw the first few pentagons to see if the point will converge or not. Here is the first 50 pentagons in a zoom-in animation: I conjecture that the sequences converge to a single point for all non-regular pentagons. If convergence occurs, how can we determine the limit point based on the initial pentagon? If the limit point exist what interesting properties does it have for the pentagon? Here is a Geogebra file that have the first 50 pentagons. This is a python code than can calculate A_n, B_n , C_n ,D_n ,E_n import math print("Number of pentagons") n=int(input()) m=max(n,50) m= min(m, 200) from decimal import Decimal import decimal decimal.getcontext().prec = m Decimal(10)**(-m) # enter your coordinates here A=[Decimal(0),Decimal(0)] B=[Decimal(0),Decimal(0)] C=[Decimal(0),Decimal(0)] D=[Decimal(0),Decimal(0)] E=[Decimal(0),Decimal(0)] print("Enter the coordinates of A_1") A[0]=Decimal(float (input())) A[1]=Decimal(float (input())) print("Enter the coordinates of B_1") B[0]=Decimal(float (input())) B[1]=Decimal(float (input())) print("Enter the coordinates of C_1") C[0]=Decimal(float (input())) C[1]=Decimal(float (input())) print("Enter the coordinates of D_1") D[0]=Decimal(float (input())) D[1]=Decimal(float (input())) print("Enter the coordinates of E_1") E[0]=Decimal(float (input())) E[1]=Decimal(float (input())) X=[Decimal(0),Decimal(0)] Y=[Decimal(0),Decimal(0)] Z=[Decimal(0),Decimal(0)] W=[Decimal(0),Decimal(0)] T=[Decimal(0),Decimal(0)] #defining some useful functions---------- def v(a,b): result= [b[0]-a[0], b[1]-a[1]] return result def crs(a, b): result = [-Decimal(0.5)*((Decimal(a[0]*b[1])-Decimal(a[1]*b[0]))*1)] return result def dis(a,b): result =[Decimal(math.sqrt((a[0]-b[0])**2+(a[1]-b[1])**2))] return result for i in range (2,n+1): AB= dis(A,B)[0] BC= dis(B,C)[0] CD= dis(C,D)[0] DE= dis(D,E)[0] EA= dis(E,A)[0] #Here to calculate A_n---------- x= CD*crs(v(D,C),v(D,E))[0] y= -CD*crs(v(E,D),v(E,B))[0]+ 2*DE*crs(v(C,B),v(C,D))[0] z= -CD*crs(v(C,B),v(C,E))[0]+ 2*BC*crs(v(D,C),v(D,E))[0] t= CD*crs(v(C,B),v(C,D))[0] X[0]=(x *B[0]+y*C[0]+z*D[0]+t*E[0])/(x+y+z+t) X[1]=(x *B[1]+y*C[1]+z*D[1]+t*E[1])/(x+y+z+t) #Here to calculate B_n---------- x= DE*crs(v(E,D),v(E,A))[0] y= -DE*crs(v(A,E),v(A,C))[0]+ 2*EA*crs(v(D,C),v(D,E))[0] z= -DE*crs(v(D,C),v(D,A))[0]+ 2*CD*crs(v(E,D),v(E,A))[0] t= DE*crs(v(D,C),v(D,E))[0] Y[0]=(x *C[0]+y*D[0]+z*E[0]+t*A[0])/(x+y+z+t) Y[1]=(x *C[1]+y*D[1]+z*E[1]+t*A[1])/(x+y+z+t) #Here to calculate C_n---------- x= EA*crs(v(A,E),v(A,B))[0] y= -EA*crs(v(B,A),v(B,D))[0]+ 2*AB*crs(v(E,D),v(E,A))[0] z= -EA*crs(v(E,D),v(E,B))[0]+ 2*DE*crs(v(A,E),v(A,B))[0] t= EA*crs(v(E,D),v(E,A))[0] Z[0]=(x *D[0]+y*E[0]+z*A[0]+t*B[0])/(x+y+z+t) Z[1]=(x *D[1]+y*E[1]+z*A[1]+t*B[1])/(x+y+z+t) #Here to calculate D_n---------- x= AB*crs(v(B,A),v(B,C))[0] y= -AB*crs(v(C,B),v(C,E))[0]+ 2*BC*crs(v(A,E),v(A,B))[0] z= -AB*crs(v(A,E),v(A,C))[0]+

Conjectures about the greatest common divisor of a vertical column of the pascal triangle.

I was playing around with pascal triangle I noticed an interesting property concerning the greatest common divisor gcd of binomial coefficients along a vertical line. Specifically, the line containing 2 is the only one where the $\gcd$ of all coefficients is greater than 1 (namely, 2). This made me wonder: What $n \in \mathbb{N}$ such that $\gcd _{k\ge1 }\left\{\binom{n+2k-2}{k}\right\}>1$ I tried every number between $2 $ and 10 by hand which all failed that made me conjecture that $n=2$ is the only number which has $\gcd _{k\ge1 }\left\{\binom{n+2k-2}{k}\right\}>1$ I wrote a simple python code to test that 2 is the only number that has this property for n in range(2,20_001): a=n for k in range (2,10_001): math.gcd(a, math.comb(n+2*k-2,k)) if math.gcd(a, math.comb(n+2*k-2,k))==1: break a=math.gcd(a, math.comb(n+2*k-2,k)) if k==10_000: print(n) print(a) print("\n") between 2 and $20,000$ the only number which has this property is 2. Another interesting thing about this sequence for $n\ne 2$ $\gcd _{1 \le k\le m}\left\{\binom{n+2k-2}{k}\right\}>1$ fail at a power of 2, in other words the for $ n \ne 2$ $\gcd _{1 \le k\le m}\left\{\binom{n+2k-2}{k}\right\}>1$ will first be broken when m is a power of 2. Here is the first 100 n and the first m that $\gcd _{1 \le k\le m}\left\{\binom{n+2k-2}{k}\right\}=1$ in the form "(n,m)" (3,2), (4,2), (5,2), (6,4), (7,2), (8,2), (9,2), (10,8), (11,2), (12,2), (13,2), (14,4), (15,2), (16,2), (17,2), (18,16), (19,2), (20,2), (21,2), (22,4), (23,2), (24,2), (25,2), (26,8), (27,2), (28,2), (29,2), (30,4), (31,2), (32,2), (33,2), (34,32), (35,2), (36,2), (37,2), (38,4), (39,2), (40,2), (41,2), (42,8), (43,2), (44,2), (45,2), (46,4), (47,2), (48,2), (49,2), (50,16), (51,2), (52,2), (53,2), (54,4), (55,2), (56,2), (57,2), (58,8), (59,2), (60,2), (61,2), (62,4), (63,2), (64,2), (65,2), (66,64), (67,2), (68,2), (69,2), (70,4), (71,2), (72,2), (73,2), (74,8), (75,2), (76,2), (77,2), (78,4), (79,2), (80,2), (81,2), (82,16), (83,2), (84,2), (85,2), (86,4), (87,2), (88,2), (89,2), (90,8), (91,2), (92,2), (93,2), (94,4), (95,2), (96,2), (97,2), (98,32), (99,2), (100,2), This sequence is also interesting because of its pattern i.e Three 2s followed by a power of 2 greater than 2. My questions are: How to prove that $n=2$ is the only $n \in \mathbb{N}$ such that $\gcd _{k\ge1 }\left\{\binom{n+2k-2}{k}\right\}>1$ For $n \ne 2$ how to prove that the first $m \in \mathbb{N}$ such that $\gcd _{1 \le k\le m}\left\{\binom{n+2k-2}{k}\right\}=1$ is always a power of 2 What is the pattern for such m? With the help of @ronno observation I was able to write a code that checked for all $n \le 10^6$ and none of them had a gcd >1 except 2

Lower bound of n th Taxi-cab number $N = a^3 + b^3 = x^3 + y^3$

Let N,a,b,x,y be distinct positive integers such that $$N = a^3 + b^3 = x^3 + y^3$$ Also known as Taxicab numbers or Taxi-cab numbers. see also : https://oeis.org/A001235 let $t(n)$ be the n th Taxi-cab number. So the first one is $t(1) = 1729$ because $1729 = 12^3 + 1^3 = 10^3 + 9^3$. Let $\pi(n)$ be the counting function of the primes up to n. And $\zeta(s)$ is the regular Riemann zeta function. Then it appears that for all positive n $$ \lfloor(\frac{\pi(n)}{\zeta(3)})^{T}\rfloor< t(n)$$ with $$T = 1+\dfrac{2+\dfrac{3+\dfrac{4+\cdots}{5+\cdots}}{4+\dfrac{5+\cdots}{6+\cdots}}} {3+\dfrac{4+\dfrac{5+\cdots}{6+\cdots}}{5+\dfrac{6+\cdots}{7+\cdots}}} $$ (The pattern is $+1$ when going up and $+2$ when going down). Or even the slightly stronger version : $$ \lfloor(\frac{\pi(n)}{\zeta(3)})^{\sqrt 3}\rfloor< t(n)$$ Notice $T = 1.728..$ (not 1.729 lol) and $\sqrt 3 = 1.732..$ (No closed form is know for T as far as I know. I incorrectly assumed it was $\sqrt 3$ here : Simplifying a complicated continued fraction expression.) Let $w(n)$ be the counting function of the Taxi-cab numbers. So $(w(t(n)) = t(w(n)) = n$. Then by looking at families of parametric solutions to $$N = a^3 + b^3 = x^3 + y^3$$ it seems manageable to prove that for large n we have $$w(n) < \sqrt n + \sqrt{\sqrt n} + \sqrt{\sqrt{\sqrt n}} $$ but this estimates $t(n)$ around n^2 what appears too high for large n. I tried some statistical ideas and sieve ideas but I did not get beyond this high estimate $t(n)$ around n^2. I tried some analytic number theory with a generalized theta function $f(s)^k = (\sum_{n>0} s^{n^3})^k$ but also without succes. How to prove one of these conjectures or get closer ? Or any good arguments pro or contra ? edit : Maybe this helps : The complete solution in positive integers to, $$x_1^3+x_2^3 = x_3^3+x_4^3$$ was given by Choudhry's On Equal Sums of Cubes (1998). For positive integers a,b,c, $$\begin{aligned} d\,x_1 &= (a^2 + a b + b^2)^2 + (2a + b)c^3\\ d\,x_2 &= (-a^3 + b^3 + c^3)c\\ d\,x_3 &= (a^2 + a b + b^2)^2 - (a - b)c^3\\ d\,x_4 &= (a^3 + (a + b)^3 + c^3)c\end{aligned}$$ where, $$(a^3-b^3)^{1/3}<\,c\,<\frac{(a^3-b^3)^{2/3}}{a-b}$$ and $d=1$, or chosen such that $\text{GCD}(a,b,c)=1$. P.S. For Choudhry's complete solution in positive integers to $x_1^3+x_2^3+ x_3^3=x_4^3$, see this post. edit 2 A simple heuristic to get a power estimate is this : $$a^3 + b^3$$ has the density $\sqrt n^3 = n^{\frac{3}{2}}$. so $$N = a^3 + b^3 = x^3 + y^3$$ has the density $ n^{(\frac{3}{2})^2} = n^{\frac{9}{4}}$. or $n^{2.25}$ But that is much larger than $n^{\sqrt 3}$ and it also much larger than what the data suggests under some logical assumptions and extrapolation. Say we estimate $t(n)$ as $C n^a $ or more precisely $1729 * n^a$. Then we have $t(30000) = 520890296211 = 1729 * 30000^{1.89..}$ I ofcourse assumed the constant $C = 1729$ is not estimated to high. see https://oeis.org/A001235/b001235.txt If you estimate the constant C much smaller such as 43 we get $$ 43 * 30000^{2.25} <t(30000) < 44 * 30000^{2.25}$$ So the final words have not been said. But from the data and arguments it seems the exponent

is going down for large n. We can also say $t(30000)$ is close to $9165 * 30000^{\sqrt 3}$ where 9165 is going down as n grows.

Conjecture: Definite existence of a prime number in the range of ${[|3^{p_i}-k\times{p_i};3^{p_i}+k\times{p_i}|]}$

My old post was closed while I had clearly tried to explain at my best. So I'll retry without posting outer links and reexplaining at most details what this conjecture is about, which was a research that I did 7 years ago when I was a college student for fun. But since I wasn't in math field I couldn't finish the work so I hope if someone is interested, who's got interest in prime numbers, to take it over if he find this explanation below convincing. Note: this post What is the appropriate way to post conjectures on Math.SE clearly says that I can post conjecture here if I understand, as long as I provide enough details to make it interesting. Origin and problematic The spark of idea came from Bertrand's postulate, which are these 3 formulas: ${\forall n\in \mathbb {N};n > 3;\exists p\in \mathbb {P} :\qquad n<p<2n-2.}$ ${\forall n\in \mathbb {N};n > 1;\exists p\in \mathbb {P} :\qquad n<p<2n.}$ ${for~~{n}\geqslant 1:\qquad p_{n+1}<2p_n.}$ What I noticed, back at that time and if I wasn't wrong since I wasn't that versed in maths. Is that this theorem was the most precise theorem for ensuring that there exist primes in a certain range. I take n = 200, I'm sure I'll find primes between 200 and 400 I take n = ${2^{10}}$, I'm sure I'll find primes between ${2^{10}}$ and ${2\times2^{10}}$ Now the problem is when the scale become higher, which means the digits are growing, 100 digits, 10 to power of a huge n digits, etc. I can take a number ${a}$ which has like 100 digits, and according to the theorem, I'm sure to find a prime between ${a}$ and ${2a}$. But I have no idea where that next prime is, it could be the next 2 numbers after ${a}$, it could be the next 10k number, it could be after 1 million number(well I doubt), etc ... Because the search range is so big. We can sumarize this into two issues: the maximum range search is too big there is no minimum range search Note : While writing this, just found out that the theorem got some precision improvements, which gives a better search range but still it's considered a bit big. Example for using ${\displaystyle x<p\leq \left(1+{\frac {1}{5\,000\ln ^{2}{x}}}\right)x}$. I can input a number ${468,991,632,168,991,632}$ which has 18 digits, and the other side will give me approximately ${468,991,688,823,352,400}$ which has 18 digits. The search range here is ${56,654,360,768}$ numbers. Too much for introducing the problematic, let me share with you some few examples of what I did research: Observations Back at the time I wanted to narrow my research only on ${prime^{prime}}$ to find out of there are any special relationships, I ended up only testing values of ${3^{prime}}$ because it took a huge time. (now creating the table and copying values from wikiversity to here is such a pain) prime number ${p_i}$ ${3^{p_i}}$ distance from next prime next prime distance from previous prime previous prime 2 9 2 11 2 7 3 27 2 29 4 23 5 243 8 251 2 241 7 2187 16 2203 8 2179 11 117 147 16 117 163 14 117 133 13 1 594 323 8 1 594 331 22 1 594 301 17 129 140 163 34 129 140 197 4 129 140 159 19 1 162 261 467 56 1 162 261 523 14 1 162 261 453 23 ..... 178 827 32 ...178 859 20 .178 807 29 ..... 364 883 30 ...365 013 14 ...364 869 31 ..... 283 947 16 ...283 963 4 ...283 943 37 ..... 997 363 50 ...997 413 2 ...997 361 41 ..... 786 403 70 ...786 473 2 ...786 401 43 ..... 077 627 52 ...077 679 74 .077 553 47 ..... 287 787 52 ...287 839 46 ..287 741 53 ..... 796 723 26 ...796 749 4 ...796 719 59 ..... 811 067 64 ...811 131 38 ...811 029 61 ..... 299 603 34 ...299 637 74 ...299 529 67 ..... 410 587 230 ...410 817 298 ...410 289 71 ..... 257 547 20 ...257 567 20 ...257 527 Note: I couldn't put all what I tested in wikiversity, it was a true pain to already calculate and compare at that time so all the other tests I've done were with pen and paper and online tools to calculate. I have tested all powers from ${3^{2}}$ till ${3^{257}}$. The last one has like between 120 and 128 digits. Even the last one in this table above has 34 digits During all these tests, I have concluded these observations: I could definitely, from ${3^{2}}$ till ${3^{257}}$, find a prime number in a range of ${[|3^{p}-3{p}~~;~~3^{p}+3{p}|]}$. Except for ${3^{67}}$ which was ${[|3^{p}-4{p}~~;~~3^{p}+4{p}|]}$ so that means, for a huge number like ${3^{257}}$ which has 123 digits, I can find at least one prime in a range of ${[|3^{257}-3\times{257}~~;~~3^{257}+3\times{257}|]}$, which is a search range of 1542 numbers, and that's for a very huge number Hypotheses Now I would have been happier if ${3^{67}}$ didn't interfere that badly so that the multiplier could be stuck at 3, sadly. So I can put 2 hypotheses: The first hypothese : The multiplier, at it's minimum range, can be considered 3. If multiple occurences after ${3^{257}}$ denies that possibility. That means either we increment the multiplier value (named ${k}$ by one everytime, like going from ${[|3^{p}-3{p}~~;~~3^{p}+3{p}|]}$ to ${[|3^{p}-4{p}~~;~~3^{p}+4{p}|]}$ then ${[|3^{p}-5{p}~~;~~3^{p}+5{p}|]}$. Or that there could be a condition for the k to be incremented to a certain number The second hypothese : I can maximise, definitely, until proven wrong, the value of ${k}$ to be the given prime number. Which means that the maximum range would be ${[|3^{p}-p\times{p}~~;~~3^{p}+p\times{p}|]}$ => ${[|3^{p}-{p^2}~~;~~3^{p}+{p^2}|]}$. Taking the ${3^{257}}$ and supposing that I didn't find the minimum. I can assume that max range would be ${[|3^{257}-{257^2}~~;~~3^{257}+{257^2}|]}$. ${257^2}$ = 66 049 so that means the search range would be 132 098 which is so incredible as a search range for a 123 digits number In a nutshell: Using the min value : ${\displaystyle \forall p_i\in \mathbb {P} ;\exists {p}\in \mathbb {P} ;\exists {k}\in \mathbb {N^*}; (2 < k < p_i):~~ p\in [|3^{p_i}-k{p_i}~~;~~3^{p_i}+k{p_i}|]}$ Using the max value : ${\displaystyle \forall p_i\in \mathbb {P} ;\exists {p}\in \mathbb {P} :~~ p\in [|3^{p_i}-{p_i}^2~~;~~3^{p_i}+{p_i}^2|]}$ Like I've said, I was able to test only the powers of 3. So I wonder if maybe other primes to primes powers could have possibly, at least that max search range, based on the given prime. So finally, why do I think that this research may be valuable: Having a good search range and existence of a minimum prime number, based on primes numbers. especially for huge numbers Possibility of application of these idea to other primes to the power of primes. Unlocking another prime to prime relationship Minimising the search range for prime numbers that are huge You who are far more proficients in Math than I, and me who forgot a lot of advanced maths because I'm in another career. I really think this conjecture has a potential and would like to know if you think that this can be ever needed in math or no. Thanks for reading, if you have any questions or remarks, don't hesitate. Although like I've said I've forgotten most of the advanced stuffs

Do there exist integers that can be written as the sum of two powers of the same prime in two ways?

Prof. Peter Cameron has a list of conjectures on his website, one of which is the following (unresolved) one: There are only six positive integers greater than 2 which can be written as the sum of two powers of the same prime in more than two ways I fail to see how an integer can be written as the sum of two powers of the same prime in even two ways:- Suppose it is true for some integer k. Then, there exists a prime p and positive integers m, n, g, h, such that $m \neq n$ and: $k = p^m + p^{m + g} = p^n + p^{n + h} \Rightarrow p^{m - n} = \dfrac{1 + p^h}{1 + p^g}$, but this is not possible as p does not divide $1 + p^h$.

Is it possible to prove that iterating this hailstone-resembling algorithm will always end in 1?

I've been messing with a rule I came up with recently, that resembles the Collatz function in formulation but shares very few practical similarities. Using p_n to represent the n^{th} prime number and c_n to represent the n^{th} composite number, the formulation is as such: \begin{cases} \text{if } n \text{ is prime:} & p_n \to p_{n+1} - p_n \\ \text{if } n \text{ is composite:} & c_n \to c_{n-1} + c_n \\ \end{cases} In words, this means, "If the number is prime, take the difference between the number and the next prime number, and if the number is composite, take the sum of the number and the previous composite number." The sequence ends when it gets to 1. (Because 4 is the first composite number, we treat c_0 as 1, meaning that 4 goes to 5.) Let's use 6 as an example: because 6 is composite, it goes to $6 + 4 = 10$; because 10 is composite, it goes to $10 + 9 = 19$; because 19 is prime, it goes to $23 - 19 =4$; and continuing this process, the sequence unfolds as: $$6 \to 10 \to 19 \to 4 \to 5 \to 2 \to 1.$$ These sequences have a tendency to act very erratically. For example, the sequence beginning with 32 demonstrates many features of this process: $${\small32 \to 62 \to 122 \to 243 \to 485 \to 969 \to 1937 \to 3873 \to 7745 \to 15489 \to 30977 \to 6 \to 10 \to 19 \to 4 \to 5 \to 2 \to 1.}$$ We can notice several things; first, when we reach an odd number, all the numbers thereafter will be odd until we reach a prime number (since the nearest composite number below an odd number will always be even). In the above sequence, all the numbers from 243 to 15489 are composite, and only because 30977 is prime do we return to an even number. Also, we can see, as the numbers get higher, they grow faster, and the chance of them being prime is much rarer. In fact, when a sequence starts growing, it looks like it'll never stop, at least for a while; the sequence starting with 95 has 595 terms, the largest of whom is the 178-digit prime number $${\scriptsize14879396952621968769079831664541974952513501961928904289230033454548697062408957128966234687844381586574195912989130942655378120463894152791647576690929892981863063412465740021 77.}$$ The next prime number is 152 greater than that, so the next item in the sequence is 152, after which the sequence rapidly goes to 1 (through the primes 4817 and then 101). Here's a picture of the start of the sequence (easier to see if you open it in a new tab): It is easy to see that these sequences can rapidly skyrocket, at a rate just barely less than 2^n. The question is: Is there a sequence that never ends (that never goes to 1)? Is there any rigorous way to prove that either all sequences go to 1 or that one sequence will never reach 1? I conjecture that they all go to 1, but I can't imagine how to go about proving it -- any help would be much appreciated!

Is it actually really easy to state conjectures, which are open and on the first view really hard to prove?

The longer I study mathematics, the more I think that we actually don’t know that much. I mean of course we don’t know that much, because theoretically mathematics is an infinitely big field of research and we as a species supposedly will only live for a finite time. So it would be reasonable to say that we don‘t know anything in mathematics. But that’s a little bit too philosophical for my question. Now I always wondered how some mathematicians even came up with theorems that are really hard to prove. But now I think it is really easy to come up with a conjecture. The only difference would be that this conjecture probably won’t have many interesting consequences. So what do I mean by that? Let me state the following: Let p be a prime number. p is called the n-th counting prime, if the sequence $123...n$ is somewhere in it’s decimal representation. So 11 would be the first counting prime and 127 the second counting prime. My conjecture would now be: for any $n \in \mathbb{N}$ the $n-th$ counting prime number does exist. So this just came to my mind and I think it would be an open problem. If it is then I would like to call it the Matthias Conjecture. And in here you could replace prime numbers with powers of two, three, seven or the round off of the imaginary part of non-trivial solutions to $\zeta(s) = 0$, where ζ is the Riemann zeta function.... Or even the real part of these solutions :) I am a little bit frustrated with this thought, because for the most part I had the feeling that we can do so much with mathematics today, but if even I could state something which is unknown and hard to prove, I rather feel like we really don’t know anything... So what do you think? I don’t really know if this fits in with this site; if not I can delete it.

Conjecture: Every Non-Zero Integer as the Difference of a Semiprime and a Prime

I would like to propose the following conjecture and seek insights or references related to it: Conjecture: Every non-zero integer n can be expressed as the difference of a semiprime q and a prime p, that is, $$n=q-p,$$ where: q is a semiprime (the product of two primes, not necessarily distinct), and p is a prime number. Numerical Verification: To gather empirical support for this conjecture, I conducted extensive numerical experiments within the range $-10,000,000≤n≤10,000,000$ (excluding $n=0$). In every case within this range, I successfully found pairs of p and q satisfying the equation $n=q-p$. No

counterexamples were observed. Example: For instance, when $n=15$: Choose p=7 (a prime), Then q=7+15=22, which is a semiprime (22=2×11). Thus, $15=22-7$. Questions: In seeking a proof or counterexample for this conjecture, what approaches or existing theories would be effective? Especially, I would appreciate advice from the perspectives of additive number theory or multiplicative number theory. Additional Information: Implementation Details: The numerical experiments were conducted using a Python program optimized with the Sieve of Eratosthenes for prime generation and parallel processing to handle large ranges efficiently. While I can provide the code upon request, the focus here is on the mathematical aspect of the conjecture. Exclusion of Zero: The case n=0 is excluded since it would require q=p, and while p is prime, q would need to be semiprime, which only occurs if p itself is a semiprime. Given that primes greater than 2 are not semiprimes, n=0 serves as an inherent exception to the conjecture. Graphical Representation: Upon observation, there is a tendency for n to stick to the upper range when it is a multiple of 6 (Especially multiples of 30), and to the lower range when n is a prime number. Motivation The motivation for this conjecture stems from the robustness of semiprimes used in RSA encryption. Specifically, semiprimes are known for their resistance to division by prime numbers, as they rarely divide evenly. This led me to consider a different approach: what if, instead of division, we use subtraction? Given that semiprimes do not divide cleanly, I hypothesized that their differences with primes might display some kind of pattern or periodicity, resulting in jumps to other numbers. From this idea, I further speculated that these "jumps" could cover all integers in a somewhat uniform manner. However, recognizing that semiprimes and primes belong to different classes, it became clear that expressing zero was not feasible. Thus, zero was excluded from the conjecture's conditions. If proven, this conjecture could offer new perspectives in number theory, with possible connections to cryptographic systems like RSA encryption. Additionally, this conjecture may inherently include basic memory management functionality. I appreciate any feedback, references, or discussions that can shed light on the validity and potential avenues for this conjecture. Thank you!

Conjecture: Every Non-Negative Integer as the Difference of a Multiple of a Prime and a Prime

In a recent post, I proposed a conjecture suggesting that every non-zero integer can be expressed as the difference between a semiprime and a prime. Conjecture: Every Non-Zero Integer as the Difference of a Semiprime and a Prime To explore this idea further, I examined a related but smaller problem. This exploration led to the following new conjecture, now including zero and focusing on non-negative integers: (Note: The range of the conjecture was incorrect, so the title and content have been revised.) Conjecture: For any prime number p, every non-negative integer k (including zero) can be expressed in the form: $$ k = p \cdot m - q $$ where m is a positive integer and q is a prime number (which may be the same as or different from p). Computational Evidence To investigate this conjecture, I conducted a large-scale computational experiment using GPU acceleration. The steps were as follows: 1.Prime Generation: Generated all primes up to a very large limit (p_{max}) and used this set for the multiples p. Created a prime bitmask for rapid prime checks up to $q_{\text{limit}}=101,010,000$. 2.Expressibility Check: For each integer k in the range $[0,100,000,000]$ (including zero), checked whether there exists a prime p (from 2 up to p_{max}) and an integer $m≥1$ such that $k=p·m-q$ for some prime q. Utilized GPU parallel processing to handle the extensive computations. Results: Prime Generation: === Result === All integers in the range [0, 100,000,000], including zero, can be expressed as p * m - q , where p is any prime between 2 and 383,393, m is a positive integer, and q is any prime. This computational evidence suggests that the conjecture holds for integers from 0 to $100,000,000$ and for any prime p from 2 to $383,393$. Although this does not constitute a formal proof, it provides a strong numerical basis for considering the conjecture's validity in general. Questions and Discussion Points Theoretical Implications: What mathematical properties of primes might underlie the ability to express every non-negative integer, including zero, in this form? Could this conjecture be connected to or derived from existing results in number theory, such as prime gaps or properties of prime distributions? Relationship to Semiprimes: While this conjecture does not directly involve semiprimes, understanding why any prime p allows for such an expression could provide insights into the original conjecture involving semiprimes. Formal Proof or Counterexamples: What approaches might one take to prove or disprove this conjecture for all primes p? Are there known counterexamples or classes of numbers that are not expressible in this form? Further Computational Work: Should further computational experiments extend beyond the current range or explore additional properties of p and q to gather more evidence? Conclusion This numerical investigation, including the ability to express zero and all positive integers in the specified form, hints at a potentially deep relationship between integers, prime multiples, and prime differences. While the computational evidence is strong, a formal proof or theoretical framework is necessary to fully understand this phenomenon. I am curious to hear thoughts from the community on possible approaches to explore or prove this conjecture.

Is there a counterexample to the No-Loop Conjecture when A is not an Artin algebra?

Let A be an Artin algebra, i.e., A is an algebra over a commutative Artin ring R that is a finitely generated R-module. The No-Loop Conjecture states that when A is an Artin algebra (or more generally an Artinian ring), if A has finite global dimension, then $$ \text{Ext}^1(S, S) = 0 $$ for all simple A-modules S. My question is: when A is not an Artin algebra, i.e., A is a general ring, is there a counterexample to the No-Loop Conjecture?

Are cage graphs Hamiltonian?

An (r, g)-cage graph is an r-regular graph with the least amount of vertices having girth g. While looking up examples of cage graphs I couldn't help myself but noticing they all seem to be Hamiltonian, with the exception of the Petersen graph. The Wikipedia article on cage graphs list the following as notable examples: and in fact, all of them but the Petersen graph are Hamiltonian (you can clearly see this in they're particular articles as their main diagram have their vertices arranged in one big circle). The $(r, 3)$ and $(r, 4)$-cages are K_r and $K_{r,r}$, respectively, both of which are clearly Hamiltonian for $r\ge 3$ (notice cage graphs only exist for $r\ge3$). Also, cage graphs are not necessarily unique for a fixed pair (r, g) and there are three $(3, 10)$-cages, the Balaban 10-cage, the Harries graph and the Harries-Wong graph (as listed by Wikipedia), all of them Hamiltonian. I looked upon some more examples and decided that was enough evidence gathering, so now I wonder how should one proceed about proving this. The amount of vertices in an (r, g)-cage is much larger than r or g in general (this is a theorem) so Bondy-Chvátal Theorem does not apply. This question has been asked before here, but it was also asking about a second (and also very interesting) conjecture on cage graphs and hasn't got much attention. This might be an open problem as far as I know, but I haven't seen anyone proposing it beyond the previous post. Update: The paper The smallest cubic graphs of girth nine (access here) lists every single one of the 18 $(3, 9)$-cages and notices they are all Hamiltonian.

Conjecture: the integer cosets of ideals are Noetherian

I have strong evidence that this fact will help prove continuity of $\pi_2(n)$ the twin prime average counter on the naturals. Continuity with respect to the Furstenberg topology that is. See my recent post history under continuity for more details. Let $U_1 \subset U_2 \subset \dots$. This sequence must eventually stabilize where $U_i=a_i + b_i\Bbb{Z}$ are integer ring cosets of ideals. It makes sense but how do we prove that b_{i+1} divides b_i? If $a +b\Bbb{Z} \subset c + d\Bbb{Z}$ then $b = \text{lcm}(b,d)$ by intersecting the two cosets. Ok then so d must divide $a-c$. Or $a= c \pmod d$. Since the ideals obviously stabilize, so too must the taken standard residue and we’re done.[U+2705] So my question now becomes are either finite unions of cosets or arbitrary unions there of also Noetherian? If arbitrary unions stabilize then I can work with open sets in Furstenberg topology. But if it’s only finite unions that become stable when in the inclusion chain [U+26D3][U+1F4A5] then I will have to do something with closed sets. So really hoping for Noetherian arbitrary unions of cosets. Clarification. Let τ be a topology that is generated by cosets found in the Furstenberg topology, which is $\sigma = \langle a + b\Bbb{Z}: a,b \in \Bbb{Z}, b \neq 0 \rangle$. In other words, τ forms a topology itself using some subset of the Furstenberg basis. Now let $U_i = \bigcup_{j = 1}^{n_i} (a_j^i + b_j^i\Bbb{Z}), \ i \geq 1$ be a sequence of finite unions of basic sets such that $U_{i} \subset U_{i+1}$ for all $i \geq 1$. Question. Does the sequence $U_1 \subset U_2 \subset U_3 \dots$ stabilize to U_n for some $n \geq 1$? I.e. for all $m \geq n$ we have that $U_m = U_n$? In other words, are finite unions of basic open sets in τ Noetherian? Attempt. I would guess the answer is a resounding "No!", because even though some cosets within the unions would stabilize, we could just keep adding in more random cosets so that the sequence just increases to some open set, not necessarily an entry in the chain. Luckily, though I thought I needed this at one point in my Topo-NT problem, I found out that approach had other unrelated errors. It is still kind of cool that coset chains are Noetherian.

Can a slice from the edge of a regular tetrahedron form a right triangle?

Let $PABC$ be a regular tetrahedron. Fix a point K on PB, and consider $\triangle AKC$. This triangle is isoceles (proven below). Can it be right? Proof that $\triangle AKC$ is isoceles: Observe that $\triangle ABK \cong \triangle CBK$ by SAS: since $PABC$ is regular, $AB \cong CB$, and $\angle ABK \cong \angle ABP \cong \angle CBP \cong \angle CPK$. Thus, $AK \cong CK$. If $K=B$ or $K=P$, this triangle is equilateral; otherwise, $\angle AKC > \angle KAC = \angle KCA$. For $|CK|$ is at its minimum when it is the altitude of $\triangle PCB$, which in an isoceles triangle happens when CK bisects $\angle PCB$, and a maximum when K is incident with P or B. When $|CK|$ is at a minimum, $\angle CKA$ is at a maximum, by Euclid I.21. My hunch is this happens when $\angle CKA$ is right, but I can't prove this. I also can't determine the angle from KC to the plane ABC.

New property of positive integers and prime numbers?

While playing with numbers, I found the following properties of positive integers and prime numbers. Properties Every positive integer n can be written in the following form \begin{align*} n = \frac{a^2 + b^2}{a + b} \end{align*} with at least 3 integer solutions. Mostly, the number of solutions is (along with probabilities of occurrence): $$\begin{matrix} 11 & 46\,\% \\ 3 & 39.4\,\% \\ 35 & 9.48\,\% \\ 19 & 3.2\,\% & \text{factorization contains square}\\ 59 & 1\,\% & \text{factorization contains 5^2}\\ 27 & 0.6\,\% & \text{factorization contains cube}\\ 107 & 0.2\,\% \\ 83 & 0.08\,\% \\ \end{matrix}$$ Moreover, every prime number p can be written in the following form \begin{align*} p = \frac{a^2 + b^2}{a + b} \end{align*} with either 3 or 11 integer solutions. The number of solutions is (along with probabilities of occurrence): $$\begin{matrix} 3 & 50.953682\,\% \\ 11 & 49.046322\,\% \\ \end{matrix}$$ Example For \begin{align*} \frac{a^2 + b^2}{a + b} = 127 \end{align*} there is exactly 3 integer solutions: $(a = 0, b = 127)$, $(a = 127, b = 0)$, and $(a = 127, b = 127)$. Question Can you confirm this result? Is this known? Any feedback is welcome.

Does $\prod_{n\ge1}\frac{\cos\frac{x}{n}}{x^{n^{2}}+1}=1-x$ for $-1<x\le1$?

I was just typing random things into Desmos and I came across this. WolframAlpha didn't give a closed form for the numerator or denominator and I don't recall coming across any formula like this before. Here is my attempt to solve it analytically: $$\prod_{n\ge1}\frac{\cos\frac{x}{n}}{x^{n^{2}}+1}=\exp\sum_{n\ge1}^{ }\ln\frac{\cos\frac{x}{n}}{x^{n^{2}}+1}$$ As you can see, I didn't really get anywhere. I also tried to expand different parts into their series expansions but it didn't seem to help. Is my conjecture that $\prod_{n\ge1}\frac{\cos\frac{x}{n}}{x^{n^{2}}+1}=1-x$ on $-1<x\le1$ true?

Conjecture about cyclic hexagons and tangent circles

Is the following conjecture true: In every cyclic convex hexagon, there exists a point P such that for every pair of opposite sides s and t, the circle through P and the endpoints of s, is tangent to the circle through P and the endpoints of t. In the diagram, circles associated with opposite sides are the same color. For brevity, I shall call such circles "opposite circles". The conjecture seems to be true, based on experiments using Geometer's Sketchpad. The conjecture is not generally true if: the hexagaon is non-cyclic the hexagon is inscribed in a non-circular ellipse if we change "hexagon" to "$2n$-gon" with $n>3$ My attempt I considered: Lines through the centres of opposite circles Lines through P tangent to opposite circles Lines that are tangent to opposite circles like an ice cream cone with two scoops of ice cream Labelling the vertices anticlockwise $ABCDEF$, then drawing AE extended, and BD extended But I could not find anything useful. Any proof must use the fact that the polygon has six sides, and is cyclic; but how? Context Recently I discovered that, in any tangential quadrilateral $ABCD$ with incentre O, the circle through A,B,O is tangent to the circle through C,D,O. (This is easily proved by extending opposite sides to form a triangle, and using the incentre-excentre lemma.) I tried to generalize this fact. I didn't generalize it, but instead came up with the conjecture here.

Conjecture: For n circles in a triangle, the maximum number of tangent points is $3n$.

Is the following conjecture true: For n non-overlapping circles (or disks) in a triangle, the maximum number of tangent points is $3n$. The tangent points include points where two circles are tangent, and points where a circle is tangent to a side of the triangle. For example, here are 7 circles and 21 tangent points. My thoughts The conjecture is not true for other polygons: for example, a single circle inscribed in a square has four tangent points. Could this be related to the fact that a circle can be surrounded by at most six other circles of the same size? I am not very familiar with graph theory, but I suspect that may be used here. Context I was playing with circles in triangles, and I started to wonder about he maximum number of tangent points.

New property of composite Mersenne numbers?

While I was playing around with Mersenne numbers, I came across an interesting thing: For p prime, $2^p - 1$ composite, $2 < b < 2^p - 1$, $\gcd(b,2^p - 1) = 1$, there exists k such $(b^k)^2 \equiv 1 \pmod{2^p - 1}$, where $b^k \not\equiv 1 \pmod{2^p - 1}$. Then the integer factorization of $b^k - 1$ contains a factor of $2^p - 1$, whereas the factorization of $b^k + 1$ contains a cofactor (i.e. another factor of $2^p - 1$). I will demonstrate this with an example: Start with $p = 11$, thus $2^{11} - 1$ is composite integer (Mersenne composite) with the factorization 23×89. Next, we choose arbitrary base b, here for example $b = 3$. By exhaustive search, we can find that $b^k = 3^{44}$, and $3^{44} \equiv 622 \pmod{2^{11} - 1}$. Note that $622^2 \equiv 1 \pmod{2^{11} - 1}$. Now we have factorization of 621 a 623 as follows. $621 = 3 \times 3 \times 3 \times \mathbf{23}$ $623 = 7 \times \mathbf{89}$ Therefore if we find $x = b^k$ such that $x^2 \equiv 1 \pmod{2^{p} - 1}$, where $x \not\equiv 1 \pmod{2^{p} - 1}$, we have got immediately the factorization of $2^{p} - 1$. Another example: Let $p = 23$, thus $2^{23} - 1$ is a composite Mersenne number with the factorization 47×178481. We choose $b = 3$. We find $x \equiv -3034178 \equiv 3^{89240} \pmod{2^{23} - 1}$ such that $x^2 \equiv 1 \pmod{2^{23} - 1}$. Now we factorize the previous and next number. $(2^{23} - 1) -3034178 -1 = 5354428 = 2 \times 2 \times 19 \times \mathbf{47} \times 1499$ $(2^{23} - 1) -3034178 +1 = 5354430 = 2 \times 3 \times 5 \times \mathbf{178481}$ And we have got the factorization of $2^{23} - 1$. My questions: Is this procedure known? Can you replicate the procedure and confirm its correctness? Is there a quick way to find non-trivial x such that $x^2 \equiv 1 \pmod{2^{p} - 1}$, where $2^{p} - 1$ is composite?

A closed form for $\int \frac{dx}{1+x^{4n}}$.

If $f(x)$ is polynomial then $\bar{f}(x)$ is obtained from f by changing the sign of coefficient x. I was trying to find a pattern in the anti derivative of $\frac{1}{1+x^m}$ and I noticed an interesting pattern when m is a multiple of 4 or equivalently $m=4n, \ n \in \mathbb{N}$. -- First Observation: For $n \in \mathbb{N}$ it seems that there always exist second degree polynomials $p_{1,n}, p_{2,n}, p_{3,n}, \dots, p_{n,n}$ $a_{k,n}$ the the coefficient of x in $p_{k,n}$ and first degree polynomials $q_{1,n}, q_{2,n}, q_{3,n}, \dots, q_{n,n}$ be with $b_{k,n}$ the the coefficient of x in $q_{k,n}$ then $$\int \frac{dx}{1+x^{4n}}= \sum_{k=1}^n \left(a_{k,n}\frac{\ln(p_{k,n}(x))-\ln(\bar{p}_{k,n}(x))}{8n}\right)+\sum_{k=1}^n \left(\frac{\arctan(q_{k,n}(x))-\arctan(\bar{q}_{k,n}(x))}{4b_{k,n}n}\right)$$ Second observation: It seems to be that $b_{n,k}=\frac{2}{a_{k,n}}$ I also believe that $q_{k,n}$ can be obtained from $p_{k,n}$ but I couldn't find a way to obtain $q_{n,k}$'s absolute term. Questions Is there a way to obtain $q_{n,k}$ from $p_{n,k}$? How to prove that for all $n \in \mathbb{N}$ there exist second degree polynomial $p_{1,n}, p_{2,n}, p_{3,n}, \dots, p_{n,n}$ $a_{k,n}$ the the coefficient of x in $p_{k,n}$ and there exist a first degree polynomial $q_{1,n}, q_{2,n}, q_{3,n}, \dots, q_{n,n}$ be with $b_{k,n}$ the the coefficient of x in $q_{k,n}$ then $$\int \frac{dx}{1+x^{4n}}= \sum_{k=1}^n \left(a_{k,n}\frac{\ln(p_{k,n}(x))-\ln(\bar{p}_{k,n}(x))}{8n}\right)+\sum_{k=1}^n \left(\frac{\arctan(q_{k,n}(x))-\arctan(\bar{q}_{k,n}(x))}{4b_{k,n}n}\right)$$ How to find $p_{n,k}$ and $q_{n,k}$?

How many times a number n is repeated in pascal's triangle?

I was playing with Pascal's triangle and noticed an interesting pattern: most numbers (except 1) appear only once (e.g., 2, 3, 4) or twice (e.g., $6 = \binom{4}{2} = \binom{6}{1}$), when excluding duplicates within the same row. To investigate this further, I wrote a simple Python script to count how many times each number appears in Pascal's triangle: import math import matplotlib.pyplot as plt import numpy as np a = [] b = [] for n in range(2, 10000): count = 0 for k in range(n + 1): for j in range(math.floor(k / 2) + 1): if math.comb(k, j) > n: break if math.comb(k, j) == n: count += 1 b.append(count) a.append(n) plt.plot(np.array(a), np.array(b)) plt.show() The first number that appears three times is 210: $$ 210 = \binom{10}{4} = \binom{21}{2} = \binom{210}{1} $$ The first number to appear four times is (3003): $$ 3003 = \binom{14}{6} = \binom{15}{5} = \binom{78}{2} = \binom{3003}{1} $$ No number is repeated five times in (1,30000) I conjecture that for any $ N \in \mathbb{N} $, there exists a number $ n $ that appears exactly $ N $ times in Pascal’s triangle. However, I have been unable to prove or disprove this. Is this conjecture true? If false, what is the maximum number of times a number can appear in Pascal’s triangle? Additionally, Assuming this conjecture holds I am curious about the sequence $ a_n $, where $ a_n $ is the first number to appear $ n $ times in Pascal’s triangle. The known values seem to be: $$ 2, 6, 210, 3003, \dots $$ This sequence does not appear in the OEIS, and finding a closed formula seems difficult due to the chaotic nature of the sequence. Can we find an upper bound on $ a_n $? Empirically, $ a_n $ seems to grow rapidly. can we find a function f such that $a_n =O(f(n))$

General prime gap counter function remains "invariant under scaling" of three of its parameters by square-free number coprime to two of its parameters

Definitions. Let all variables be integers. When we sum over the set of residues r such that $r^2 = k^2 \mod \text{lcm}(\ell,d)$, we're allowed to take any residue $r' \in r + \text{lcm}(\ell,d)\Bbb{Z}$ in place of r in the formula. This is true via construction (basic inequality solving / modular arithmetic), and the ceiling term takes care of anything that would otherwise be "too large" in magnitude. For square-free $l, n \geq 1, \ k \geq 0, x\in \Bbb{Z}$, we define the following counting formula. $$ H_n(k,\ell,x) =\sum_{d \mid \text{rad}(n)}\mu(d)\sum_{r^2 = k^2 \mod \text{lcm}(\ell,d)}\left(\left\lfloor\frac{x - r}{\text{lcm}(\ell,d)}\right\rfloor - \left\lceil\frac{-r}{\text{lcm}(\ell,d)} \right\rceil + 1\right) $$ It is known that for $x \geq 0$, this counts EXACTLY the number of $z \in [0, x]$ such that $z^2 \neq k^2 \mod \text{lcm}(\ell, p)$ for any p prime dividing n. And therefore $H_{1,1}(p_n\#, x)$ for $x \in [p_n +2, p_{n+1}^2-2]$ (sieve of Eratosthenes bounds) will count EXACTLY the number of $z \in [p_n +2, x]$ that are twin prime averages. The reason for "$p_n + 2$" there is that the lower averages got sieved out as we incremented the primorial. Conjecture. Fix $n\geq 1$. Let $l\geq 1$ with $\gcd(l,n) =1$, $k\geq 0$, and $x \in \Bbb{Z}$. For any prime q such that $q \nmid n\ell$ we have that, the $H_n(k,\ell,x)$ expression remains invariant under scaling of the parameters k, ℓ, x by q. In other words $$ H_n(qk,q\ell, qx) = H_n(k,\ell,x) $$. Attempt. I figured out a nicer, more expressive proof method. If we set $A(k,d) = \{r \in \Bbb{Z}/d : r^2 = k^2\}$, then we can easily prove that $A(qk, q\ell d) \simeq A(k, \ell d)$ as sets (of solutions). Using an unnamed property of modular arithmetic, that should be familiar to most modular arithmetic students. Namely, the "cancelling out a factor in the modulus": $$ r^2 = k^2 \mod \ell d \\ \iff \\ r^2-k^2 = 0 \mod \ell d\\ \iff \\ q^2(r^2 - k^2) = 0 \mod q\ell d \\ \iff \\ (qr)^2 = (qk)^2 \mod q\ell d $$ Then if $\text{res}(A(k, \ell d))\subset \Bbb{Z}$ is a choice of residues for the solutions $r \in A(k, \ell d)$, then $q\cdot \text{res}(A(k,\ell d)) = \text{res}(A(qk,q\ell d))$ is a possible choice of residues for $r \in A(qk, q\ell d)$, because $r^2 = k^2 \mod \ell d \iff (qr)^2 = (qk)^2 \mod q\ell d$. Thus, we may transform the expression for $H_n(qk, q\ell, qx)$ in one step. Edit. I was finally able to prove this on my own (for the most part). But there is still an unanswered question that I have about it. Proof of Conjecture. Since $\gcd(q, \ell d) = \gcd(\ell, d) = 1$ we may replace every lcm in the formula by multiplication. $$ H_n(qk,q\ell,qx) = \sum_{d \mid \text{rad}(n)}\mu(d)\sum_{r^2 = (qk)^2 \mod q\ell d}\left(\left\lfloor\frac{qx - r}{q\ell d} \right\rfloor - \left\lceil\frac{-r}{q\ell d} \right\rceil + 1 \right) \\ = \sum_{d \mid \text{rad}(n)}\mu(d)\sum_{r^2 = k^2 \mod \ell d}\left(\left\lfloor\frac{qx - qr}{\ell d} \right\rfloor - \left\lceil\frac{-qr}{\ell d} \right\rceil + 1 \right) \\ = H_n(k,\ell, x) $$ The summation rearrangement is via the above lemma. Question. Why must q be a prime

number in this proof strategy, and not just coprime (to ℓn)? I know from code-testing that any coprime q, i.e. any $q\in \Bbb{N}$ such that $\gcd(q, \ell n) = 1$ doesn't work. But when q is a prime, the test code runs to completion without an assert (counter-example). Conjecture Verification Code. from sympy import * def H(k, l, n, x): S = 0 for d in divisors(n): T = 0 for r in range(l*d): if (r ** 2 - k ** 2) % (l * d) == 0: T += floor((x-(r % (l*d)))/(l*d)) - ceiling((-r % (l*d))/(l*d)) + 1 S += totient(d) * T return S N = 8 M = 16 x = Symbol('x') for n in range(1, N): print(f"n={n}:") P = primorial(n) for k in range(0, M): for l in range(1, M): if gcd(l, P) == 1: for m in range(n+1, M): # Already coprime to p_n# q = prime(m) if gcd(q, l) == 1: h_k_l_x = H(k, l, P, x) h_qk_ql_qx = H(q*k, q*l, P, q*x) print(f" H({q}*{k},{q}*{l},p_{n}#,{q}*{x}) = {h_qk_ql_qx}") print(" =? ") print(f" H({k},{l},p_{n}#,{x}) = {h_k_l_x}") if h_k_l_x != h_qk_ql_qx: print("CONJECTURE FAILURE") assert 0 print('------------------------') Extended Conjecture. For any $k \geq 0$ and $\ell \geq 1$ such that $\gcd(\ell, p_n\#) = 1$, we have that, for $\gcd(q,\ell p_n\#) = 1$: $$ H_n(k,q\ell,x) \leq H_n(k,\ell, x) = H_n(qk,q\ell,qx) $$ Conjecture verification was for small cases using the SymPy code and a few extra lines. Note. I didn't want to make another question for this, so perhaps there is some proof mechanism by which this extended conjecture also goes through. I think by construction (examining the set-wise inclusion-exclusion formula) we have the inequality.

Does $(a-c)>(b-a)$ imply that $(s-a)^2 + c^2 < (s-b)^2 + a^2$ for integer valued $0 \leq a, b, c \leq s.$

In a paper on theoretical voting systems, I have come to the need to prove (or disprove) the following statement: If \begin{equation} (a-c)>(b-a), \end{equation} then \begin{equation} (s-a)^2 + c^2 < (s-b)^2 + a^2, \end{equation} for all non-negative integer values $0 \leq a, b, c \leq s.$ This holds for all of the combinations of $a, b, c,$ and s that I have tried. I have tried to do a proof by contradiction but am unable to derive a contradiction. Any help would be greatly appreciated!

Congruences between CM Modular forms of different weight for special primes

While playing around with modular forms with CM, I found something interesting: Set $f_{27.2.a.a}:=q\prod_{n=1}^\infty (1-q^{3n})^2(1-q^{9n})^2=\sum_{n=1}^\infty \alpha_n q^n$ to be a cusp form of $\Gamma_0(27)$, weight 2 with $\mathbb Q(\sqrt{-3})$ CM. Set $f_{9.4.a.a}:=q\prod_{n=1}^\infty (1-q^{3n})^8=\sum_{n=1}^\infty \beta_n q^n$ to be a cusp form of $\Gamma_0(9)$, weight 4 with $\mathbb Q(\sqrt{-3})$ CM. It is easy to see when $n\equiv 0,2\bmod 3$ we have $\alpha_n=\beta_n=0$, so we are only interested in the case $n\equiv 1\bmod 3$, especially when $n=p\equiv 1\bmod 3$ is a prime. I try to compare $\alpha_p,\beta_p\bmod p$ for $p\le 5000$. And I conjecture that $\alpha_p\equiv\beta_p\bmod p$ if and only if $(4p-1)/27$ is an odd perfect square. These p-s form the OEIS sequence A275878, namely standard Jacobi primes. Is there some number theory facts behind this?

Computing $\int_0^{\pi(1-1/N)}\mathrm{d}\phi\,\left(\frac{\sin^N(\phi+\pi/N) -\sin^N(\phi)}{\sin^N(\phi+\pi/N) +\sin^N(\phi)}\right)^2$

I have managed to come up with the conjecture $$I_2(N) = \int_0^{\pi(1-1/N)}\mathrm{d}\phi\,\left(\frac{\sin^N(\phi+\pi/N) -\sin^N(\phi)}{\sin^N(\phi+\pi/N) +\sin^N(\phi)}\right)^2 = \pi \left(\frac{N-1}{N}\right)\left(\frac{2N-1}{3N}\right).$$ This holds trivially for $N=2$. In the limit of $N\rightarrow\infty$, the conjecture also holds: by performing an expansion, keeping only the lowest order terms, and substituting $u=\cot\phi$, I can write $$\lim_{N\rightarrow\infty}I_2(N) = \int_{-\infty}^\infty \mathrm{d}u \, \frac{\tanh^2(u\pi/2)}{1+u^2},$$ which I can solve using contour integration. For $N=4$, I can also show consistency with the ansatz. Expanding $\sin(\phi+\pi/N)$ with the $\sin$ addition formula and making the substitution $u=1+\cot\phi$, I can write $$I_2(4) = \int_0^\infty \mathrm{d}u\,\frac{1}{u^2-2u+2}\left(\frac{4-u^4}{4+u^4}\right)^2 =\int_0^\infty \mathrm{d}u\, f(u).$$ Annoyingly, this is not the integral of even function. Contour integration is therefore not easy. However, I can split the integrand into odd and even components $f(u) = f_e(u) + f_o(u)$. For $N=4$, these components are fortunately possible to evaluate with contour integration and some minor manipulations. I have attempted something similar for general N, but have so far been unsuccessful, as $f_o(u)$ no longer takes such a convenient form. I am very confident that this conjecture is true for $N>1$. I have performed numerical integration up to $N=50$, and it is in perfect agreement with my conjecture even for non-integer values of N (although I am specifically interested in the solutions for positive integers $N>2$), as you can see in the figure. A general proof of this, however, has been elusive, and I would appreciate any suggestions. I have also tried differentiation of my expression with respect to N to see if I can show equality that way. Unfortunately, as far as I can tell, the integral only becomes more unpleasant. N." />

If matrix A has a left inverse C, is AC orthogonally diagonalizable with all eigenvalues 0 or 1?

Let A,C be matrices such that $CA = I$. Then AC is defined. I conjecture the following: AC is orthogonally diagonalizable. Its eigenvalues are either 1 or 0. It is Hermitian Informally, if A has a left inverse C, then switching their order can either preserve information as is (eigenvalue 1) or lose it (eigenvalue 0), but can't do anything else with it (transform it otherwise). Is the above correct? Is this part of a theory?

Conjecture about gcd of Faulhaber's Polynomials.

Now asked on MO here Let $f_n $ be the $ n $-th Faulhaber polynomial. In this question, I observed the following divisibility properties: If $ n $ is even, then $ f_n $ is divisible by $ f_2 $. If $ n > 1 $ is odd, then $ f_n $ is divisible by $ f_3 $. However, it seems that Faulhaber polynomials do not share any additional common factors (ignoring the denominator). More precisely, for $ n \neq m $ and $n,m>1$, we have $$ \gcd(f_n, f_m) = \begin{cases} f_3, & \text{if both } n \text{ and } m \text{ are odd,} \\ f_2, & \text{if both } n \text{ and } m \text{ are even,} \\ f_1, & \text{otherwise.} \end{cases} $$ Beyond these cases, no additional common factors seem to exist. Added: As @sil mentioned in the comments $\gcd(f_9,f_{10})= n (n+1) \left(n^2+n-1\right)$ However for all $n,m\le100$ that is the only counter example that I found. I used this ugly Mathematica code to generate the gcds For[m = 1, m < 101, m++, For[j = 1, j < m + 1, j++, If[m != j, Print[m, j, Factor[PolynomialGCD[Sum[k^m, {k, 1, n}], Sum[k^j, {k, 1, n}]]]] ,]]] Added: Using the code in this answer I have checked that for $n,m<1000$ there are no other counter examples. Here are the first 14 Faulhaber's Polynomials: $$f_1=\frac{n(n+1)}{2}$$ $$ f_{2}=\frac16 n (1+n) (1+2 n)$$ $$f_{3}=\frac14 n^2 (1+n)^2$$ $$f_{4}=\frac1{30} n (1+n) (1+2 n) (-1+3 n+3 n^2)$$ $$f_{5}=\frac1{12} n^2 (1+n)^2 (-1+2 n+2 n^2)$$ $$f_{6}=\frac1{42} n (1+n) (1+2 n) (1-3 n+6 n^3+3 n^4)$$ $$f_{7}=\frac1{24} n^2 (1+n)^2 (2-4 n-n^2+6 n^3+3 n^4)$$ $$f_{8}=\frac1{90} n (1+n) (1+2 n) (-3+9 n-n^2-15 n^3+5 n^4+15 n^5+5 n^6)$$ $$f_{9}=\frac1{20} n^2 (1+n)^2 (-1+n+n^2) (3-3 n-n^2+4 n^3+2 n^4)$$ $$f_{10}=\frac1{66} n (1+n) (1+2 n) (-1+n+n^2) (-5+10 n+3 n^2-11 n^3+2 n^4+9 n^5+3 n^6)$$ $$f_{11}=\frac1{24} n^2 (1+n)^2 (10-20 n-3 n^2+26 n^3-5 n^4-16 n^5+4 n^6+8 n^7+2 n^8)$$ $$f_{12}=\frac1{2730}n (1+n) (1+2 n) (-691+2073 n-287 n^2-3285 n^3+1420 n^4+2310 n^5-1190 n^6-1050 n^7+525 n^8+525 n^9+105 n^{10})$$ $$f_{13}=\frac1{420} n^2 (1+n)^2 (-691+1382 n+202 n^2-1786 n^3+367 n^4+1052 n^5-326 n^6-400 n^7+125 n^8+150 n^9+30 n^{10})$$ $$f_{14}=\frac1{90} n (1+n) (1+2 n) (105-315 n+44 n^2+498 n^3-217 n^4-345 n^5+182 n^6+144 n^7-81 n^8-45 n^9+24 n^{10}+18 n^{11}+3 n^{12})$$

How to find all minimal upper bounds under graph minor relation?

Let $H\leq G$ denote that H is a minor of G. Given two graphs H_{1} and H_{2}, is there an algorithm to find all minimal upper bounds G of H_{1},H_{2} ? That is, find all graphs G such that $H_{1},H_{2}\leq G$ and $H_{1},H_{2}\leq H\leq G$ implies $H\cong G$. By the graph minor theorem, the set of such G is finite up to isomorphism. I conjectured that $|V(G)|\leq |V(H_{1})|\times |V(H_{2})|$, but I failed to prove it. There is an example that the branch sets of G corresponding to H_{1} and H_{2} share at least two vertices, but I can't construct a counter example to the conjecture either.

Radium Rabbit Conjecture (Version 2.0)

Radium Rabbit Conjecture (Version 2.0) Why This Version 2.0? The previous version of this conjecture led to some misunderstandings, and the discussion was closed before reaching a conclusion. In this revised version, I have clarified my observations and the open question I seek to answer. I hope this will allow for a more precise discussion and lead to a deeper understanding of the underlying mathematical structure. Radium Rabbit Conjecture The conjecture posits that, for a triangle formed by distinct prime numbers, the square of its area will always have a fractional part of $3/16=0.1875$. Specifically, the square of the area follows the form: $$S^2 = A + \frac{3}{16}$$ where A is some integer. Key Observations Modular Arithmetic Connection It has been established that the square of the area follows a modulo 16 pattern related to $3/16$. However, what has been proven so far is only that the result is a multiple of 3, not necessarily fixed at $3/16$ itself. I want to understand why the fraction is always exactly $3/16$ and not, for example, $6/16$ or $9/16$. Distinct Prime Triangles and Their Properties Such triangles do not form right-angled triangles due to the nature of prime numbers. They are neither congruent nor similar to each other, further suggesting a unique underlying property. Equilateral Triangle and a Possible Clue The squared area of an equilateral triangle follows a specific modular arithmetic pattern where the fractional part is $3/16$. This hints at a deeper structure that might explain why distinct prime triangles also conform to the same $3/16$ fraction. Open Question While I have observed and verified the $3/16$ pattern, I have yet to prove why this must always be the case. The key question I am seeking to answer is: Why does the squared area of a triangle formed by distinct primes always take the form , rather than any other multiple of $3/16$? I appreciate any insights or discussions that could help in proving this conjecture. Final Note I truly enjoy discussing mathematics with all of you, and I appreciate the opportunity to refine this idea further. Thank you!

Has anyone constructed a graph that shows implications between conjectures?

Does such a graph exist or is it considered redundant/unhelpful/infeasible? Such a graph could help fill in corollary results from a proof or its contrapositive. Relatedly, I have found some data aggregation for theorems and directed graphs for mathematical concepts or fields. I think that a 'conjectree' would also be useful for discovering bottlenecks, or for the deliberate exploration of problems that have fewer known consequences (leaves?).

Conjecture: For every prime p, there exists at least one prime in the range $[p^3-p, p^3+p]$

Conjecture: For every prime p, there exists at least one prime in the range $[p^3-p, p^3+p]$. Verified for all primes up to 1000. Let me know if it holds for all. Example Let’s work through the conjecture for all prime numbers up to 17, calculating p^3, the interval $[p^3 - p, p^3 + p]$, and confirming whether at least one prime exists within it, inclusive. The primes up to 17 are: $2, 3, 5, 7, 11, 13, 17$. Here’s the step-by-step verification: $p = 2$: $2^3 = 8, 8 - 2 = 6, 8 + 2 = 10$. Interval: $[6, 10] = \{6, 7, 8, 9, 10\}$. Primes: 7 Prime exists: Yes. $p = 3$: $3^3 = 27, 27 - 3 = 24, 27 + 3 = 30$. Interval: $[24, 30] = \{24, 25, 26, 27, 28, 29, 30\}$. Primes: 29 Prime exists: Yes. $p = 5$: $5^3 = 125, 125 - 5 = 120, 125 + 5 = 130$. Interval: $[120, 130] = \{120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130\}$. Primes: 127 Prime exists: Yes. $p = 7$: $7^3 = 343, 343 - 7 = 336, 343 + 7 = 350$. Interval: $[336, 350] = \{336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350\}$. Primes: $337, 347$ Prime exists: Yes. $p = 11$: $11^3 = 1331, 1331 - 11 = 1320, 1331 + 11 = 1342$. Interval: $[1320, 1342] = \{1320, 1321, 1322, ..., 1341, 1342\}$ (23 numbers). Primes: $1321, 1327$ Prime exists: Yes. $p = 13$: $13^3 = 2197, 2197 - 13 = 2184, 2197 + 13 = 2210$. Interval: $[2184, 2210] = \{2184, 2185, ..., 2209, 2210\}$ (27 numbers). Primes: $2203, 2207$ Prime exists: Yes. $p = 17$: $17^3 = 4913, 4913 - 17 = 4896, 4913 + 17 = 4920$. Interval: $[4896, 4920] = \{4896, 4897, ..., 4919, 4920\}$ (25 numbers). Primes: $4903, 4919$ Prime exists: Yes.

Primality and the GCD of Stirling number of the second kind.

Let $ \left\{ \begin{matrix} n \\ k \end{matrix} \right\} $ denote the Stirling number of the second kind. $$ \sum_{k=0}^n {n \brace k} x^{\underline{k}} = x^n $$ where $ x^{\underline{k}} $ is the falling factorial. Also, the Stirling number can be expressed as: $$ \left\{\begin{array}{l} n \\ k \end{array}\right\}=\frac{1}{k!} \sum_{j=0}^k(-1)^{k-j}\binom{k}{j} j^n=\sum_{j=0}^k \frac{(-1)^{k-j} j^n}{(k-j)!j!} $$ $$x=x^{\underline{1}}$$ $$x^2 = x^{\underline{1}}+x^{\underline{2}} $$ $$x^{\color{red}{3}} = x^{\underline{1}} + \color{red}{3}x^{\underline{2}} +x^{\underline{3}} $$ $$x^4=x^{\underline{1}} +7 x^{\underline{2}} + 6x^{\underline{3}} +x^{\underline{4}} $$ $$x^{\color{red}{5}}=x^{\underline{1}}+\color{red}{15}x^{\underline{2} } +\color{red}{25}x^{\underline{3}} +\color{red}{10}x^{\underline{4}} +x^{\underline{5}}$$ $$x^6=x^{\underline{1}}+31x^{\underline{2} }+90x^{\underline{3}} +65x^{\underline{4}}+15x^{\underline{5}}+ x^{\underline{6}}$$ $$x^{\color{red}{7}}=x^{\underline{1}}+\color{red}{63}x^{\underline{2} }+\color{red}{301}x^{\underline{3}} +\color{red}{350}x^{\underline{4}}+\color{red}{140}x^{\underline{5}}+ \color{red}{21}x^{\underline{6}}+x^{\underline{7}}$$ I came across an interesting conjecture: For $n>2$ $$ \gcd\left(\left\{ \begin{matrix} n \\ 2 \end{matrix} \right\},\left\{ \begin{matrix} n \\ 3 \end{matrix} \right\},\dots, \left\{ \begin{matrix} n \\ n-1 \end{matrix} \right\} \right) > 1 \quad \text{if and only if} \quad n \text{ is prime}. $$ Furthermore, if $ n $ is prime, then $$ \gcd\left(\left\{ \begin{matrix} n \\ 2 \end{matrix} \right\},\left\{ \begin{matrix} n \\ 3 \end{matrix} \right\},\dots, \left\{ \begin{matrix} n \\ n-1 \end{matrix} \right\} \right) = n. $$ I was unable to prove this result rigorously, but I wrote a Python script to check it computationally, and the conjecture holds up to $ n = 10,000 $. Here is my implementation: import math stop=1 def is_prime(n): if n <= 1: return False for i in range(2, int(math.sqrt(n)) + 1): if n % i == 0: return False return True a=[1] max=10_000 nmax=int(max*(max+1)/2) for i in range (2,max+1): for n in range (1,nmax+1): if n<math.floor((i*(i-1))/2)+1: continue elif n==math.floor((i*(i-1))/2)+1 : a.append(1) elif n==math.floor((i*(i+1))/2) : a.append(1) break else: m=n-(math.floor((i*(i-1))/2)) s=math.floor(((i-2)*(i-1))/2)+m-1 a.append(a[s-1] +(m)*a[s]) for i in range (3,max+1): if stop ==0: print("false") break s=a[math.floor((i*(i-1))/2)+1] for n in range (1,nmax+1): if n<=math.floor((i*(i-1))/2)+1: continue elif n>=math.floor((i*(i+1))/2) : if s>1 and s==i : if is_prime(i)==True: print(i) else: stop=0 break else: s=math.gcd(s,a[n-1])

A Generalization of Hilbert's Nullstellensatz?

This question comes from the (intuitive) observation, that the failure of Hilbert's Nullstellensatz comes from the failure of the base field k to "detect" all roots of a polynomial. In the case of an algebraically closed field, all roots of any polynomial can be successfully detected. Therefore it seems to be natural to ask the following question, a generalization of the Nullstellensatz on non-algebraically closed fields: Question: if k is any characteristic zero field, $S \subseteq k[x_1,\cdots,x_n]$ a set of polynomials that can be factored into linear factors in $k[x_1,...,x_n]$, does it hold that $I(Z(S))=\sqrt{\langle S \rangle}$? Notations: $Z(S)$ is the set of zero points; $I(X)$ is the set of polynomials that vanishes on X; $\langle S \rangle$ is the ideal generated by S; $\sqrt I$ is the (nilpotent) radical. Edit: it's actually not a generalization.

A conjecture about multiplying odd numbers by 3 in binary

Setup : Let $I_n=\underbrace{11\cdots1}_{n \text{ times}}$ and $Z_n=\underbrace{00\cdots0}_{n \text{ times}}$ Example: $x=11001=I_2 \space Z_2 \space I_1$ Note: We are dealing only with odd numbers ! Motivation behind the problem : To compute $3 \times x$, the classical way is: $2x+x$ But it requires addition and bit-shifting ! So, I asked myself : Can we find an algorithm that computes $3\times x$ with no adders, no carry logic ? Here's the algorithm I've made to answer this question ! My algorithm is purely a rearrangement of the input bits under fixed rules. My algorithm and the conjecture : First, let

$\color{blue}{\zeta(n)} = \begin{cases} 01Z_{n-2}10 \space \text{if } n\ge2 \\ \\ 100 \text{ if } n=1\end{cases}$ and $x=I_{n_k}Z_{m_k} \cdots I_{n_2} Z_{m_1}I_{n_1}$ such that $\forall i>0: n_i,m_i>0$ To compute $3x$, first prepare the table below : $\color{red}{10}\space\space\space I_{n_k-2} \space\space \color{blue}{\zeta(m_k)}$ $\space\space\space\space\space\space\space I_{n_{k-1}-2} \space\space \color{blue}{\zeta(m_{k-1})}$ $\space\space\space\space\space\space\space \cdots$ $\space\space\space\space\space\space\space I_{n_2-2} \space\space \color{blue}{\zeta(m_1)}$ $\space\space\space\space\space\space\space I_{n_1-2} \space\space \color{red}{01}$ To start the algorithm, we assemble the digits from $\color{red}{01}$ up to $\color{red}{10}$ The behaviour of I_{-1} : If I_{-1} was before 1, we delete it and that's it ! If I_{-1} was before 0, we delete it and apply the inv function The inv func works as follows: If I_{-1} was after $\color{red}{10}$, he converts it to $\color{red}{1}$ and that's it ! If I_{-1} was after $\color{blue}{100}$, he converts it to $\color{blue}{011}$ and that's it ! If I_{-1} was after $\color{blue}{01Z_{m_{i}-2}10}$, he converts it to $\color{blue}{01Z_{m_{i}-2}01}$ and that's it ! Example: Suppose $x=11001=I_2 \space Z_2 \space I_1$ First let's prepare our table ! $\color{red}{10}\space\space\space I_{2-2}=I_0 \space\space \color{blue}{\zeta(2)}=0110$ $\space\space\space\space\space\space\space I_{1-2}=I_{-1} \space\space \color{red}{01}$ Starting the algorithm from $\color{red}{01}$ up to $\color{red}{10}$ we get: $\color{red}{10}\space\space\space I_0 \space\space \color{blue}{\operatorname{inv}(}0110\color{blue})=0101$ $\space\space\space\space\space\space\space .. \space\space \color{red}{1}$ Assembling, we get $3x=\color{red}{10} \space 0101 \space \color{red}{1}$ $\Rightarrow 3x=1001011$ Another example: $x=10011101=I_1 \space Z_2 \space I_3 \space Z_1 \space I_1$ First let's prepare our table ! $\color{red}{10}\space\space\space I_{1-2}=I_{-1} \space\space \color{blue}{\zeta(2)}=0110$ $\space\space\space\space\space\space\space I_{3-2}=I_{1} \space\space \color{blue}{\zeta(1)}=100$ $\space\space\space\space\space\space\space I_{1-2}=I_{-1} \space\space \color{red}{01}$ Starting the algorithm from $\color{red}{01}$ up to $\color{red}{10}$ we get: $\color{red}{1}\space\space\space .. \space\space 110$ $\space\space\space\space\space\space\space I_{1} \space\space \color{blue}{\operatorname{inv}(}100\color{blue})=011$ $\space\space\space\space\space\space\space .. \space\space \color{red}{1}$ Assembling, we get $3x=\color{red}{1} \space 110 \space 1 \space 011 \space \color{red}{1}$ $\Rightarrow 3x=111010111$ Now the conjecture is : $\forall x \in 2\mathbb{N}+1,$ my algorithm will always produce $3x$? Thanks for help !

Conjecture about a chain of six circles whose tangent points lie on a circle

Six black circles (not necessarily the same size) form a closed chain, in which each circle is externally tangent to its two neighbors. The six tangent points all lie on a red circle. Three line segments connect the centres of opposite black circles. Based on experimentation, I conjecture that the three line segments must intersect at a single point. Is my conjecture true? I tried to use circle inversion, but that does not seem to make the problem any easier. Note that Brianchon's Theorem does not apply here, because the red circle is not necessarily normal to the black circles, so the red circle is not necessarily tangent to the sides of the hexagon with vertices at the black circles' centres. If there are eight black circles instead of six, the four line segments do not necessarily intersect at a single point. This question was inspired by this question about a chain of four circles inscribed in a circle. Edit A theorem similar to my conjecture is Dao's Theorem. But they are different: In my conjecture, each of the six circles must be tangent to its two neighbors, but this is not required in Dao's theorem. (At the end of page 40 in the link, it says "Let (O_{ijk}) meets (O_{jkh}) again at P_{jk}'". Later in "Problem 6", they make use of the points P_{jk}'.) In Dao's theorem, each of the six circles goes through P_{ij},P_{jk},P_{ik} for some consecutive i,j,k, but this is not required in my conjecture.

What is the status of the Palis conjecture?

Jacob Palis (born in 1940) sadly passed away last month. I read the lead of his Wikipedia article, and it says: "He proposed the Palis conjecture, which influenced the development of the theory of dynamical systems, and also of its applications to other sciences. He was a world leader in chaos theory research. Palis was an influential figure in the development of mathematics in Brazil." (emphasis is mine) What is the Palis conjecture? In which paper was it proposed? Is it still open? What is the progress that have been made so far? Why is it important? I am only an undergraduate student of math, interested in dynamical systems theory, and curious about this. EDIT: Judging by other topics in MathOverFlow, it's not only one conjecture, but many conjectures ("the Palis conjectures" or "Palis' Program"). I am now very confused about this.

$n \mid 5\times2^{v_2(3n+1)}+9$, has no solutions ? ($\forall n>1$ and $n\equiv 1\pmod 4$)

The Conjecture: Let $n\in \mathbb{N^*}$ then $n,v_2(3n+1)>1$$\Rightarrow n \not\mid 5\times2^{v_2(3n+1)}+9$ Notice that, $v_2(3n+1)>1 \Leftrightarrow 4 \mid 3n+1 \Leftrightarrow n\equiv 1\pmod 4$ My attempt : $v_2(3n+1)=2 \Leftrightarrow 3n +1 \equiv 4 \pmod 8 \Leftrightarrow n\equiv 1 \pmod 8$ Suppose $n\mid 5\times2^{v_2(3n+1)} +9=5\times2^2+9=29$ $\Rightarrow n = 29$, but $29\equiv 5 \pmod 8$ $v_2(3n+1)=3 \Leftrightarrow 3n +1 \equiv 8 \pmod {16} \Leftrightarrow n\equiv 13 \pmod {16}$ Suppose $n\mid 5\times2^{v_2(3n+1)} +9=5\times2^3+9=49$ $\Rightarrow n = \begin{cases} 7 ,

\text{but it's not } 13 \pmod {16} \\ \\ 49, \text{but } 49\equiv 1 \pmod{16} \end{cases}$ In general, I managed to find the following congruences : $v_2(3n+1)=p \Leftrightarrow n \equiv \begin{cases} \displaystyle \frac{2^p-1}{3} \pmod {2^{p+1}} \text{ , if } p \equiv 0 \pmod 2 \\ \\ 3+10 \times \displaystyle \frac{2^{p-1}-1}{3} \pmod {2^{p+1}} \text{ , if } p \equiv 1 \pmod 2 \end{cases}$ Now suppose $n < 2^{p+1}$, Case one: p even ! $\Rightarrow n = \displaystyle \frac{2^p-1}{3} \Rightarrow 2^p-1\mid 3(5\times2^p +9) = 3(5\times(2^p - 1) + 14) \Rightarrow 2^p-1\mid 21 \Rightarrow n \mid 7 \Rightarrow n=7$ but $2^p-1=21 \Rightarrow 2^p=22$, which is a contradiction ! Case two: p odd ! $\Rightarrow n = 3+10 \times \displaystyle \frac{2^{p-1}-1}{3} \Rightarrow 5\times 2^p -10 + 9 \mid 3(5\times2^p+9)$ $\Rightarrow 5\times2^p -1 \mid 3(5\times2^p-1 + 10) \Rightarrow 5\times2^p -1 \mid 3 $ but $5\times2^p -1=3 \Rightarrow 5\times2^p=4$, which is a contradiction ! Thus, one have to check my conjecture only $\forall n>2^{p+1}$. I've also checked the conjecture $\forall n<10^6$, by python : def val_2(n): return (n & -n).bit_length() - 1 for n in range(5,pow(10,6),4): if (5*pow(2,val_2(3*n+1))+9)%n == 0: print(f'Contradiction at n={n}') Thanks for help !

Conjecture : $\forall d>1, d \mid 3^{n+1}-2^n \Rightarrow \log_2(3d+1) \not\in \mathbb{Z}$?

The conjecture : Let $n \in \mathbb{N^*} \Rightarrow \forall k >1, \displaystyle \frac{4^k-1}{3} \not\mid 3^{n+1}-2^n $ Note that : the statement above is equivalent to the title by considering $d=\displaystyle\frac{4^k-1}{3}$ we are dealing with a d such that $\gcd(d,3)=1$ because $3\mid d \Rightarrow 3\mid 3^{n+1}-2^n$, an immediate contradiction ! $\Rightarrow v_3(4^k-1)=1$, so that $\gcd(\displaystyle\frac{4^k-1}{3},3)=1$ Also, by LTE : $v_3(4^k-1)=v_3(4-1)+v_3(k)=1+v_3(k)=1, \Rightarrow v_3(k)=0$ In other words, $\gcd(d,3)=1 \Leftrightarrow \gcd(k,3)=1$ My attempt : $\displaystyle\frac{4^k-1}{3} \mid 3^{n+1}-2^n \Rightarrow 2\mid n$ and $k\equiv 1 \pmod 3$ Suppose n is odd, we will use the Jacobi symbol : $\displaystyle \left(\frac{3^{n+1}}{d} \right)$ $=$ $\displaystyle \left(\frac{2^n}{d} \right)\Rightarrow \displaystyle \left(\frac{2}{d} \right) = +1$ On the other hand, we have this identity :$\displaystyle \left(\frac{2}{d} \right) = (-1)^{\displaystyle \frac{d^2-1}{8}} = (-1)^{\displaystyle \frac{d-1}{4}\times \displaystyle \frac{d+1}{2}} $ $d-1=\displaystyle \frac{4^k-1}{3}-1 = \displaystyle \frac{4^k-4}{3} \Rightarrow \displaystyle \frac{d-1}{4} = \frac{4^{k-1}-1}{3}$, an odd integer $d+1=\displaystyle \frac{4^k-1}{3}+1 =\displaystyle \frac{4^k-2}{3} \Rightarrow \displaystyle \frac{d+1}{2} = \frac{2^{2k-1}-1}{3}$, an odd integer $\Rightarrow \displaystyle \left(\frac{2}{d} \right) = -1 $, which is a contradiction ! $\Rightarrow n$ is even As n is even $\Rightarrow \displaystyle \left(\frac{3}{d} \right) = +1 \Rightarrow \left(\frac{d}{3} \right) = (-1)^{\displaystyle \frac{d-1}{2} \times \frac{3-1}{2}} = +1$ Notice that, $d=\displaystyle \sum_{i=0}^{k-1} 4^i \equiv \displaystyle \sum_{i=0}^{k-1} 1^i \pmod 3 $, since $4 \equiv 1 \pmod 3$ $\Rightarrow d \equiv k \pmod 3 \Rightarrow k \equiv 1 \pmod 3$, since $\displaystyle \left(\frac{d}{3} \right)=+1$ Thanks for help !

Conjecture : $\forall n>1, d\mid 3^n-2^n \Rightarrow v_2(d+1)<n$

The conjecture : $\forall n>1, d\mid 3^n-2^n \Rightarrow v_2(d+1)<n$ where $v_2(x)$ denotes the 2-adic valuation of x, i.e the highest power of 2 that divides x e.g : $v_2(12)=2$ since $12=2^2 \cdot 3$ Initially, let's check the case when $d=3^n-2^n$ $\Rightarrow v_2(d+1)=v_2(3^n+1-2^n)$ Notice that, $v_2(3^n+1)=\begin{cases} 1 \text{ , if } n \equiv 0 \pmod 2 \\ \\ 2 \text{ , if } n \equiv 1 \pmod 2 \end{cases}$ $\Rightarrow v_2(d+1) =\begin{cases} v_2(2^1\times(\displaystyle \frac{3^n+1}{2}-2^{n-1})) = 1 \text{ , if } n \equiv 0 \pmod 2 \\ \\ v_2(2^2\times(\displaystyle \frac{3^n+1}{2^2}-2^{n-2}))=2 \text{ , if } n \equiv 1 \pmod 2 \end{cases} $ You can take $n>2 \Rightarrow v_2(d+1) < n$, the case $n=2$ is correct since 2 is even and $2>1$ Also, the case $d=1$ is trivial since $v_2(d+1)=v_2(1+1)=1<2<n$ @Aphelli noticed that $d\mid 3^n-2^n \Leftrightarrow \displaystyle \left(\frac{3}{2}\right)^n \equiv 1 \pmod d $ So it's enough to prove the following : $\gcd(d,6)=1 \Rightarrow v_2(d+1) < \text{ord}_d \displaystyle \left(\frac{3}{2}\right)$ My attempt : Firstly, we clearly notice that $d\mid 3^n-2^n \Rightarrow d$ is odd $ \Rightarrow 2\mid d+1$ Let's assume by contradiction, that $v_2(d+1)\ge n \Rightarrow 2^n \mid d+1 \Rightarrow d=2^nk-1$ $\Rightarrow 2^nk-1 \mid3^n-2^n$, (for some integer $k \ge 1$) e.g : for $k=1 \Rightarrow 2^n -1 \mid 3^n-2^n=3^n-(2^n-1)-1$ $\Rightarrow 2^n-1 \mid 3^n-1 \Rightarrow n$ is odd , (since $2\mid n \Rightarrow 3\mid 3^n-1$) Let's use the Jacobi symbol : $\displaystyle \left(\frac{3}{2^n-1} \right)=1 \Rightarrow \displaystyle \left(\frac{2^n-1}{3} \right) = (-1)^{\displaystyle\frac{3-1}{2} \times \frac{2^n-1-1}{2}}=-1$ On the other hand, $2^n-1\equiv (-1)^n-1 \equiv -2 \equiv 1 \pmod 3$ $\Rightarrow \displaystyle \left(\frac{2^n-1}{3} \right) = \displaystyle \left(\frac{1}{3} \right) = +1$, which is a contradiction ! From A Conjecture about the upper bound of $v_2(3^n+d)$ (proved by Joris Nieuwveld) we conclude the following : Fix $k \in \mathbb{N^*} \implies 2^nk-1 \mid3^n-2^n$ has only finite solutions for $n>1$ $2^nk-1 \mid3^n-2^n \Rightarrow (2^nk-1)\lambda = 3^n-2^n$, (for some integer $\lambda \ge 1$) $\Rightarrow 2^n(\lambda k +1)=3^n+\lambda \Rightarrow v_2(3^n+\lambda) \ge n$ which won't last longer, since $\forall d \in \mathbb{N^*}, \exists n_0 \in \mathbb{N^*}$ such that : $\forall n>n_0 : v_2(3^n+d)<n$, where n is a positive integer. Also, if someone managed to optimize the constant C_n mentioned on : Analyzing Yu, K.: p-adic logarithmic forms and group varieties we may deduce some tighter bounds on n or λ, which would contradict the fact that $\lambda < 3^n - 2^n$ I've also checked the conjecture $\forall n<10^2$, by python : from sympy import divisors def val_2(n): return (n & -n).bit_length() - 1 for n in range(2,pow(10,2)): for d in divisors(pow(3,n)-pow(2,n)): if val_2(d+1) >= n : print(f'Contradiction at n={n} , d={d}') break Also, setting G_n to be the set of gaps $n-v_2(d+1)$, $\forall d\mid 3^n-2^n $ and $g(n)=\min(G_n)$ we remark that $g(n) > 0$ and $g(n)=\mathcal{O}(n)$ So, as n grows up $v_2(d+1)$ became much smaller than n which is assured by our conjecture ! from sympy import divisors import matplotlib.pyplot as plt def val_2(n): return (n & -n).bit_length() - 1 plt.grid(True) plt.xlabel("n") plt.ylabel("g(n)") for n in range(2,pow(10,2)): G=[] for d in divisors(pow(3,n)-pow(2,n)): G.append(n-val_2(d+1)) plt.scatter(n,min(G),c='black') plt.show() Thanks for help !

Conjecture : $\forall n>1 , \exists a,b \in \mathbb{N^2}$ such that : $\tau(3^n-2^n)=2^a \cdot3^b$

Motivation : I wanted to understand more the behaviour of the divisors of 3^n-2^n, to solve this conjecture : Conjecture : $\forall n>1, d\mid 3^n-2^n \Rightarrow v_2(d+1)<n$ So I tried to examine initially: $\tau(3^n-2^n)$ (the number of divisors d of 3^n-2^n) My attempt: I literally have no idea of how we can prove this result, but I discover it from my python research routine ! from sympy import divisor_count from sympy.ntheory import factorint for n in range(2,100): print(n,factorint(divisor_count(pow(3,n)-pow(2,n)))) Here's a chart of the factorization of $\tau(3^n-2^n)$, ($\forall n < 10^2 $)

Proving (the lower bound that) N exceeds product of primes under special congruence constraints

Let $S = \{p_1, p_2, \dots, p_k\}$ be a finite set of at least two distinct odd primes, i.e., $k \ge 2$. Consider the system: $ N \equiv p_i \pmod{p_i^2 (p_i - 1)} \quad \text{for all } p_i \in S, $ where N is square-free. Then how can we prove the following claim: $N > \prod_{i=1}^{k} p_i$ I observed this empirically, but I am unable to give a correct rigorous proof for it (tried 3-4 different methods, getting stuck every time). Can anybody please help me out?

Conjecture: In a "happy triangle", the expected product of side lengths is π.

Definition of happy triangle On a unit circle, choose three uniformly random independent points A,B,C. Inside the circle, choose a uniformly random independent point D. Triangle ABC is called "happy" if it contains D. Conjecture Is the following conjecture true: In a happy triangle, the expected product of the three side lengths is π. I simulated 2×10^7 happy triangles, and the average product was $3.14184188\approx1.00007933\pi$. My thoughts Letting $X=\text{product of the three side lengths}$, I tried (but failed) to find the probability distribution function $P(X<x)$ so that I could find the probability density function and thus $E(X)$. The expected product of the three side lengths is not the cube of the expected side length, because the three side lengths are not independent random variables. (A simulation suggests that the expected side length is approximately 1.509.) Other elegant properties? A happy triangle seems to have many elegant properties.

Proving a number of base 2 non-recurring if converted to base 10 having the same decimal point position from the right of the number

I have a precision P_2 and P_{10} defined as the position of the decimal point from the right of the number. P_2 for base 2, P_{10} for base 10, for example: $$ \begin{align*} \\ P_2(110.101_2) &= 3_{10} \\ P_2(1.10101_2) &= 5_{10} \\ \\ P_{10}(110.101_2) &= P_{10}(6.625_{10}) &= 3_{10} \\ P_{10}(1.10101_2) &= P_{10}(1.65625_{10}) &= 5_{10} \end{align*} $$ I would like to prove that $P_2(x)=P_{10}(x)$ for any number of x that can be represented in base 2 without recurring number, e.g. $0.0011..._2$ At the moment , I cannot compute an exception to prove a contradiction, so I am left with this conjecture. I tried to breakdown input as an expanded base 10 equation (unsubscripted terms are in base 10): $$ \begin{align*} a_2 &= (... b2 \cdot 2^{2} + b1 \cdot 2^{1} + b0 \cdot 2^{0}) \times 2^{-p1} \\ a_{10} &= (... b2 \cdot 10^{2} + b1 \cdot 10^{1} + b0 \cdot 10^{0}) \times 10^{-p2} \end{align*} $$ Now, I am left with how to proof if $a_2=a_{10}$, then $p1 = p2$ is the same in both equation. I am not sure if I can work on the factorisation here like: $$ \begin{align*} 10^{-p2} &= (2 \times 5)^{-p2} \\ 10^{-p2} &= 2^{-p2} \times 5^{-p2} \\ \frac{10^{-p2}}{5^{-p2}} &= 2^{-p2} \end{align*} $$ Then, I could substitute 2^{-p2} in that a_2 equation, but I have to handle $\frac{1}{5^{-p2}}$ every other terms in the infinite sum. I have a feeling I am making things more complicated here. What approach can I use to proof this equation? Or is there any properties that I use as a reference that they are equal?

There exists no mult. subsemigroup $S \subset\Bbb{Z}$ of a ring such that $S + 1$ is never prime?

By prime number we mean $\Bbb{P} = \{ \pm 1, \pm q : q \text{ is prime in the usual sense}\}$. Conjecture. There exist no mulitiplicative subsemigroup S of $\Bbb{Z}$, such that $S + 1$ is never prime. Any such S which are a counter-example of this are called semigroup spaceships [U+1F6F8] because they perfectly dodge all (quite randomly placed) primes ("astroids"). So in essence, adding 1 to a subsemigroup is never enough to build a nice spaceship, a subsemigroup is not complex enough. Can you provide a counter-example to this claim? Clearly if there exists such an S it must be infinite, because it contains $x

\neq \pm 1$, and so $x^2,x^3, \dots$ as well. It sufficient to prove there is no cyclic subsemigroup $S = \langle x \rangle$ such that $(S + 1) \cap \Bbb{P} = \varnothing$. Or in other words, for all $x \in \Bbb{Z}$ $$ x^n + 1 \in \Bbb{P} \text{ i.o. over } n \in \Bbb{N} $$

Can we prove this conjecture related to the trisection of the angle?

I don't have much reference on trisecting an angle , but while trying to design a problem on this topic , I stumbled upon the following simple situation : In triangle ABC, the line segments CI and CJ are the two trisectors of $\angle ACB$. The circumscribed circle of triangle CIJ intersects the line segment CA at C, D, and the line segment BC at C, E. So here is my conjecture that I observed, after many constructions, and I don't know if it's already known or even true: the straight lines AB and DE are PARALLEL. I attempted an analytical approach that turned out to be too complicated, so I continue to search a proof. Any ideas are welcome.

Steiner-Lehmus-like Conjecture: If corresponding trisectors of two angles of a triangle are congruent, then the triangle is isosceles

I am trying to find a property of trisectors that recalls the famous Steiner-Lehmus theorem on bisectors. So, here is, after several observations, a new conjecture that I wish to demonstrate: Conjecture. In ABC, AI and BJ are the two "upper" trisectors of angles A and B respectively, we know that $AI=BJ$, as shown in the figure, then ABC is isosceles. Here is my incomplete attempt at the proof: According to the sine law, we can easily find: $$\sin(3a)\sin(2a+3b) = \sin(3b)\sin(2b+3a) \tag1$$ and after developing and first transposition, we can write $$\cos(a-3b) - \cos(3a-b) = \cos(5a+3b) - \cos(5b+3a) \tag2$$ so $$\sin(a+b)\sin(2a-2b) = \sin(a-b)\sin(4a+4b) \tag3$$ and $$\sin(a-b)\left[\cos(a-b) - 2\cos(a+b)\cos(2a+2b)\right] = 0 \tag4$$ Finally, or else $a=b$, then ABC isosceles, or else $$\cos(a-b) - 2\cos(a+b)\cos(2a+2b) = 0 \tag5$$ that we can write as $$\cos(a-b) - \cos(a+b) - \cos (3a+3b) = 0 \tag6$$ and ultimately $$2\sin(a)\sin(b) + \cos(C) = 0\text{ with }C=\pi-3a-3b \tag7$$ This last equation is impossible if angle C is acute. So the conjecture is true in any acute ABC, but then, what about an obtuse triangle? Any suggestions?

What is the probability that a plane through three random points on the surface of the Earth intersects the Moon?

Looking up at the night sky, I wonder: What is the probability that a plane through three random points on the surface of the Earth intersects the Moon? (The points are independent and uniform.) Let: $d=$ distance between centre of the Earth and centre of the Moon $r=$ radius of the Moon (Figure not to scale.) Simulations suggest that the probability is simply r/d, for any values of r and d, assuming that the two spheres are disjoint. (It seems that the radius of the Earth does not matter.) If this is true, then plugging in $r=1737$ km and $d=384400$ km, the probability is approximately $\frac{1}{221}$. Using sphere point picking, each random point has two variables, so there are a total of six variables. It seems that such a simple result should be provable without integrating over six variables, but I cannot find a way. The $2D$ case is not elegant. Fun fact The probability is indeed r/d. If we replace "moon" with "sun", the probability is approximately $\frac{7\times 10^5}{1.496\times 10^8}\approx\frac{1}{214}$. So there is a greater chance that the plane will intersect the sun, than the moon.

Are $1,2,5,10$ the only solutions of $3^{n+1} \pmod {2^n} > 2^n-1.5^n$?

Introduction : Put $r_n=2^n \{ 1.5^n \} $, i.e : the remainder of $3^n \pmod {2^n}$. If the following inequality holds: $\forall n>1 , r_n<2^n-1.5^n$ (an open problem). It has been proved that the function $g(k)$ occurring in Waring's problem, is given by the formula : $g(k)= 2^k +\left \lfloor{\displaystyle 1.5^k} \right \rfloor -2$ This was noted by J. A. Euler, the son of Leonhard Euler, in about 1772 My attempt : I wondered what if we considered the next power 3^{n+1} , will the inequality stay true ? However , I checked the conjecture with PARI/GP , $\forall n < 10^5$: { for(n=1, 10^5, if (lift(Mod(3, 2^n)^(n+1)) > 2^n - (3/2)^n, print(n))) } It took around 41.44 seconds to finish , the only solutions were $\color{red}1,\color{red}2,\color{red}5,\color{red}{10}$.

Conjecture: The largest root of $\sum_{k=0}^n\cos\left(\frac{k\pi}{2}\right)\binom{n}{k}x^k$ is approximately $\frac{n}{\pi}$ or $\frac{2n}{\pi}$.

Is the following conjecture true: For large n, the largest root of $\displaystyle\sum\limits_{k=0}^n\cos\left(\frac{k\pi}{2}\right)\binom{n}{k}x^k$ is approximately $\dfrac{n}{\pi}$ for odd n, or $\dfrac{2n}{\pi}$ for even n. For example, for $n=100$ we have $1-\binom{100}{2}x^2+\binom{100}{4}x^4-\binom{100}{6}x^6+\dots-\binom{100}{98}x^{98}+x^{100}$. The largest root is $x\approx 63.6567$, whereas $\frac{2(100)}{\pi}\approx63.6620$. Their ratio is approximately

0.99992. I do not know why $\frac{2(100)}{\pi}$ is close to a root, nor why that root is the largest root. Context: This question was inspired by my question "True or false: If you square the coefficients in the expansion of $(x+1)^n$, the resulting polynomial has n distinct real roots."

Why does $\sum_{p\leq n}\sigma_{0}\left(p-1\right)\approx2n$?

I noticed that: $$\sum_{p\leq n}\sigma_{0}\left(p-1\right)\approx2n$$ where σ_{0} is the number-of-divisor function, and the sum is over primes. Any idea if and why this could hold for larger n ? And don't have any clue where to start, since it was a random observation while tracking the number of operations for some unrelated algorythm... I ran a script and got the following results: n SUM 10 10 100 160 1000 1804 10000 19069 100000 191593 1000000 1926814 10000000 19324386 100000000 193577243 1000000000 1937069910

Conjecture on upper bound for sum of $\sum_{a \in S} 1/a$ for S satisfy $\mathrm{lcm}(a,b) > n$ for every $a \neq b \in S$

Recently I found an interesting problem on number theory which stated For a set S of integers ranging from 1 to n such that for every $a\neq b,~a,b \in S$ we have that $\mathrm{lcm}(a,b) > n$, prove that $\sum_{a \in S} 1/a < 3/2$. The solution for this problem is quite simple. Denote S_a the set of multiples less than n of a; then for every $a\neq b, a,b \in S$ we must have $S_a \cap S_b = \emptyset$ and obtain the "trivial" bound of $n \ge \sum |S_a| \ge \sum (n/a - 1)$. However when I want to make the constant $3/2$ lower the same strategy no longer works. I believe that the best constant possible is something around $\ln 2$ as n approaches infinity and the set not containing 1. A few examples are: the set of the least power of p greater than $\sqrt n$ for every prime $p \le n,$ or the set of all numbers greater than $n/2$, both result in a sum of $\ln 2$ (as n approaches infinity, since for $n=5$ there is already a counter example of $S=\{2,3,5\}$). A very similar problem has been conjectured by Erdős before, namely problem of finding the best upper bound for $\sum_{a\in S} 1/a$, but for the set S satisfying a is not divisible by b for every $a,b \in S$. But I couldn't find a source of this problem online. If anyone could share on how to tackle this problem or just the name of it, I'd be very appreciative.

Do the area, semiperimeter and longest side of a cyclic quadrilateral always satisfy the triangle inequality?

My experimental data supports the following conjecture. Can this be proved? Conjecture: Let a convex quadrilateral be inscribed in a circle of radius $R>0$. Let a denote the longest side, s the semiperimeter, and A the area of the quadrilateral. Then the numbers $a,s,\frac{A}{R}$ satisfy the triangle inequality. Update 17-Oct-2025: I think I have a proof, posting it as answer below. Generalization of the question for cyclic polygons.

Does decomposition of PDFs guarantee independence of random variables?

Is this conjecture correct? If not, can it be modified to a correct one: Let X,Y be continuous RVs with joint PDF $f(x,y)$. Then X,Y are independent iff there exists functions g, h such that $$f(x,y) = g(x)h(y).$$ This seems obviously true if g and h are the PDFs of X,Y. I conjecture this to be true without making that qualification: any g,h that multiply to f are

sufficient. But I don't know how to prove that.

A conjecture about a difference expression of n positive numbers

The starting point for this question is a set of n positive ordered numbers: $$ x_{1} \, \ge \, x_{2} \, \ge \, \ldots \, \ge x_{n} \, > \, 0 \; .$$ From these numbers difference expressions can be formed: $$ D \, = \, \sum_{i=1}^{n}\, c_{i} x_{i} \; .$$ Each c_{i} coefficient obeys $c_{i} \in \{-1, 1\}$ and so for a fixed n, there are 2^{n} possible difference expressions. I define the class of guaranteed non-negative difference expressions as follows. Definition A difference expression D is said to be guaranteed non-negative (gnn) if its value is non-negative regardless of the values of the x_{i} variables. For example, it is fairly easy to see that the following difference expressions are gnn: A difference expression D with the first $\lceil n/2 \rceil$ coefficients c_{i} equal to 1 and the remaining c_{i} equal to -1 is gnn. Hence, when $m = \lceil n/2 \rceil$, the following is gnn: $$ D_{1} \, = \, \sum_{i=1}^{m}\, x_{i} - \sum_{i=m+1}^{n}\, x_{i} $$ A difference expression where the c_{i} coefficients alternate between 1 and -1, starting with $c_{1} = 1$, is gnn. Hence, $$ D_{2} \, = \, \sum_{i=1}^{n}\, (-1)^{i+1} \, x_{i}$$ is gnn. My question concerns the following conjecture about difference expression D_{2}. Conjecture There does not exist a gnn difference expression $\hat{D}$ such that $D_{2} > \hat{D}$. My problem is to prove or disprove this conjecture. I believe it is correct. I have a couple of remarks. Remark 1 I think I have a proof that the following are necessary and sufficient conditions for a difference expression D to be gnn: $$\sum_{i =1}^{j} \, c_{i} \, \ge 0 \; , \; j = 1, 2, \ldots n $$ Remark 2 My question is related to the 2-way number partitioning problem. See the following: Cerquides, J. and Meseguer, P. 'Speeding Up 2-way Number Partitioning', ECAI, 2012. doi:10.3233/978-1-61499-098-7-223

$a_1,\dots,a_n$ periodic sequences summing to $p_1,\dots,p_n$ over each of their resp. periods, then their sums synch. to some value $\leq\sum_i p_i$.

Conjecture. Let $(a_i(j))_{j \geq 0}$ be sequences of natural numbers ≥ 1. For example $a_1 = \overline{2} = 2,2,2,2, \dots$, is the constant 2, but $a_3 = \overline{2,1,2}$ is not. Define $B = B(a_1, \dots, a_n)$ to be the first point (minimum B) at which the sequences synchronize in sum, ie. where $\sum_{x = 0}^{k_i} a_i(x) = B,$ for some $k_i \in \Bbb{N} \cup 0$, $\forall i = 1..n$. Then, it's true that $$B \leq 2(p_1 + \dots + p_n)$$ is an upper bound for B, where $p_i = \sum_{x = 0}^{T_i - 1} a_i(x)$ is the sum of the sequence a_i over a single period $T_i =$ the period of a_i. Question. How can we prove this via any means (they don't have to be elementary style methods)? Attempt. I thought we could do it by induction on the number of sequences involved. So by induction we have: $$ \forall J \subset \{1, \dots, n\} $$ of size $|J| = n-1$, we would have $\sum_{j \in J} a_j^{k_j} = B(a_j : j \in J) \leq \sum_{j \in J} 2p_j$, where $p_j = \sum_{x = 0}^{T_j} a_j(x)$ and $T_j =$ the period of a_j. So for example if $n = 3$ we have: $$ B(a_1, a_2) \leq 2(p_1 + p_2)\\ B(a_2, a_3) \leq 2(p_2 + p_3) \\ B(a_1, a_3) \leq 2(p_1 + p_3) \\ $$ But I'm not sure how to conclude that $B(a_1, a_2, a_3) \leq 2(p_1 + p_2 + p_3)$ as a result... So perhaps maybe induction is out of the question?

Rational points and sections on a family of genus-2 hyperelliptic curves

I am interested in the proof or disproof of some conjectures about rational points and sections over $\mathbb{Q}$ for the following family of genus-2 hyperelliptic curves: $$ C_t: f(x,a)\, g(x,a)\, h(x,a)\ = y^2, $$ Where, $$f(x,a)=\left(x^2+2ax-\left(a^2+4\right)\right)$$ $$g(x,a)=\left(a^2x^2-2ax+\left(2-a^2\right)\right)$$ $$h(x,a)=\left(\left(2-a^2\right)x^2+4ax-8\right)$$ And the parameter is, $$a(t)=\left(\frac{t^2+2t-1}{t^2+1}\right)$$ $\text{where } x, y, t \in \mathbb{Q}$ The following rational sections are known to lie on C_t , $$ S1:\left(x,y\right)=\left(\frac{(t^2+2t+3)(3t^2-2t+1)} {2(t^2+1)(t^2+2t-1)} ,\pm \frac{(-1-2t+t^2)^7} {8(1+t^2)^5(-1+2t+t^2)^2} \right) $$ $$ S2:\left(x,y\right)=\left(\frac{t^2-2t+3}{2(t-1)} ,\pm \frac{(t^2-2t-1)^3(t^2+2t-1)^2} {8(t-1)^3(t^2+1)^2} \right) $$ $$ S3:\left(x,y\right)=\left(\frac{3t^2+2t+1}{2t(t+1)} ,\pm \frac{(-1-2t+t^2)^3(-1+2t+t^2)^2} {8t^3(1+t)^3(1+t^2)^2} \right) $$ A rational section means a point $(x(t),y(t)) \in C_t(\mathbb{Q}(t))$ Edit The original form of Conjecture 2 stated that there were no rational points on the nonsingular fibres other than those arising from the three known sections. Arlo provided a counterexample showing this to be false. The conjecture has therefore been revised to include the lifting condition, which is the condition relevant to the original Diophantine problem. The conjectures are: Apart from the points at infinity of the smooth projective model, there are no other nontrivial affine rational sections of C_t apart from $S1$,$S2$ and $S3$. For nonsingular fibers $(a \neq \pm 1)$, there are no rational points on $C_t(\mathbb{Q})$ satisfying the lifting condition, other than those arising from the three known sections. Origin of the question: This family of genus-2 curves emerges from the 3x3 magic squares of squares problem. Hence, these conjectures have some correspondence with the problem. Clarification about the quotient curve The curve C_t arises from a quotient transformation of the original Diophantine problem. Therefore, non-trivial rational points on C_t give candidate solutions, but they must also satisfy the lifting condition to correspond to solutions of the original problem. The quotient coordinate is related to the original coordinate by $$ x=\frac{1}{k}+2k. $$ Hence a rational quotient point lifts to a rational k only when $$ 2k^2-xk+1=0 $$ has a rational solution, equivalently when $$ x^2-8 $$ is a square in $\mathbb{Q}$. Therefore, the intended question is whether there exist any additional rational points on C_t satisfying this lifting condition, beyond those obtained from the known sections. Evidence from a Specialisation at $t=-7$ I examined the specialized fibre at $t=-7$, $a = a(-7)$. Using Magma, the Jacobian of the specialized curve satisfies the rank bound $$ \operatorname{rank}\!\left(\mathrm{Jac}(C_{-7})(\mathbb{Q})\right) \le 4. $$ A search found only: the unique point at infinity; the specializations of the three sections $(S1, S2, S3)$, each with both choices of sign for y. No further rational points were found. This

computation is not intended as a proof of the conjectures, but provides some computational evidence that the three known sections may account for all rational points. I would especially appreciate suggestions on applicable methods (for example, Chabauty-Coleman, Mordell-Weil sieves, descent, or covering collections), or references to related computations.

A “block” generalization of factorions

I’ve been exploring a generalization of factorions-that is, numbers equal to the sum of factorials of their digits-and wanted some feedback on the concept. Let $n \ge 1$ where n is an integer. A number N is an n-factorion if you can split N into consecutive groups of n digits each, take the factorial of these n-digit blocks and sum them, and they all sum to N. Keep in mind this does require N to have a number of digits divisible by n. By this logic, a typical factorion would be considered a 1-factorion. For example, consider 2,763 as a candidate 2-factorion. It would turn into $27! + 63!$ which is equal to approximately 1.98×10^{88} which is pretty obviously way off. As you can see, 2-factorions alone would be monstrously big, the smallest candidate possible being 3,628,800 (10!). Clearly the smallest one would have to be hundreds or thousands of digits. I personally conjecture that there is no upper bound to how large n can be. The only thing holding regular factorions back was the fact that 9! can only work for so many digits, however we can keep theoretically increasing up to 99!, 999!, etc. I’d love feedback on whether this generalization is interesting, or if there are known results related to this topic. Are there any theoretical approaches for estimating or bounding the size of n-factorials without brute-force computation?

Does there exist a number such that the first 16 numbers of its Collatz sequence mod 4 contain four 1s, 2s, 3s, and 4s?

I was setting a sudoku with a very unique constraint and I came across this. I thought it wouldn't be that hard to find a number, but after writing a python program to find one, I am doubtful of its existence. Let $C(n)$ be a 16 element sequence representing the first 16 numbers of n's Collatz sequence mod 4. Let $\DeclareMathOperator{Count}{Count}\Count(n)=(\Count_0(n),\Count_1(n),\Count_2(n),\Count_3(n))$ where $\Count_k(n)$ is the number of times k appears in $C(n)$. Using my program, I found that for $1\le n<100000$, if $\Count_3(n)=4$ and $\Count_k(n)\ge3$ for $0\le k\le2$, then $\Count(n)=(3,3,6,4)$. Since there are 3903 values of n that fit these constraints in this range and they all produce the same $C(n)$, I am tempted to conjecture that these conditions on n force $\Count(n)=(3,3,6,4)$. I've tried to reverse engineer this using my basic knowledge of modular arithmetic to no avail. Can anyone help me out? Edit: Here is the program I have been using: def collatz16(n): seq = [0]*16 seq[0] = n%4 for i in range(1, 16): n = (n >> 1) if (n & 1) == 0 else 3*n + 1 seq[i] = n%4 return seq c = 0 for i in range(100000): seq = collatz16(i) if((seq.count(0) >= 3) and (seq.count(1) >= 3) and (seq.count(2) >= 3) and (seq.count(3) == 4)): c+=1 print(f"{i} {[seq.count(0), seq.count(1), seq.count(2), seq.count(3)]} {seq}") print(c)

If H, K and L are subgroup such that H commutes with K and L then is $H\ast K\ast L$ a subgroup?

If H and K are subgroup of a group $(G,\ast,e)$ then I know that $H\ast K$ is a subgroup of when H is commutable with K: so I am searching a counterexample showing that if a subgroup X commutes with the subgroup X, Y and Z then $X\ast Y\ast Z$ is not necessarly a subgroup when only X commutes with X and Y but I was not able to find it (I just tried to work with S_3 but I failed) so that I thought to put here a specific question. Could someone help me, please?

Is the area of a cyclic polygon of nine or more sides greater than the square of the geometric mean of the sides?

The side lengths of a convex polygon do not uniquely determine the shape of the polygon but if the polygon is cyclic then the shape is uniquely determined by the side lengths. Consider a cyclic n-gon. For $n=3,4$ Heron's formula and Brahmagupta's formula give the area but for $n \ge 5$ there is no such simple formula in terms of the sides. So instead, we can ask given the side lengths $a_1, a_2,\ldots, a_n$, $n \ge 5$ what are the bounds on the area A. Let $\displaystyle s = \frac{\Sigma a_i}{2}$ be the semi-perimeter. Then the isoperimetric inequality gives a trivial upper bound $\displaystyle A \le \frac{s^2}{\pi}$. The lower bound is much more complicated however experimental results shows the possibility of an interesting an simple lower bound for $n \ge 9$. Definition: Let $a = (a_1 a_2 \cdots a_n)^{1/n}$ be the geometric mean of the sides. I estimated the probability $P_n := P\left(A \ge a^2\right)$. My experimental data gave $$ P_3 = 0 \\ P_4 \approx 0.5556 \\ P_5 \approx 0.9961 \\ P_6 \approx 0.99995 \\ P_7 \approx 0.9999995 \\ P_8 \approx 0.99999999 $$ For $n = 9$, even after 5×10^9, I could not find a single polygon where $A < a^2$. Based on this data, I conjecture that Conjecture: The area of a cyclic polygon of nine or more sides is greater than the square of the geometric mean of the sides. Can this conjecture be proved or disproved?

Conjecture: a constant-free equation is solvable in a group G if and only if it is solvable in its generating set B for any $G=\langle B\rangle$

Conjecture. Let G be a group and B any set of generators for G. That is to say $G = (G, \cdot) = \langle B \rangle$. Then for any equation $E=F$ in G that is constant-free, we have that $E=F$ is solvable in general elements $x_i \in G \iff$ it is solvable purely in the generators $b_i \in B$. An equation $E=F$ that is constant-free in G means that we merely use the group law $\cdot$ and/or the inverse operation $(\cdot)^{-1}$, and variables to form the equation. And no constant symbols are allowed! And one cannot "get rid" of 1 by rewriting with $yy^{-1} (\equiv 1)$; that's not allowed. In other words both sides of the equation $E = F$ must be "reduced words." That takes care of the the previous counterexample by Malady of $E:x=1$ having only 1 as a solution. For example, if $x^2y^3z^{-4} = 1$ has a solution $(x,y,z) \in G^3$ then there exists $(a,b,c) \in B^3 : a^2b^3c^{-4} = 1$ and (vise versa obviously). Where juxtaposition means the group operation $\cdot:G\times G \to G$. Question. Can you prove this or come up with a counterexample? If you can't prove it; can you come up with a modified version that you can prove (such as restricting to abelian groups)? Or alternatively, if you do come up with a counter-example, can you modify the statement in such a way that we bypass the given counterexample?

Given an n-gon, by how much must we increase the length of each of k chosen sides so that they form a k-gon?

The polygon inequality states that the sum of any $n-1$ sides of a n-gon greater than the n-th side. Let $n \ge 4$ and $3 \le k < n$. Let a n-gon have positive side lengths $ a_1 \le a_2 \le \dots \le a_n$. Select a subset $b_1, b_2, \ldots, b_k$ of the n lengths $a_i, i = 1,2,\ldots, n$. These k sides may or may not form a k-gon themselves depending on weather they satisfy the k-gon inequality or not. Now we increase the length of each of these k by a fixed quantity t. As t increases, the variance of the resulting k increased lengths $b_i + t$ decreases and for sufficiently large t all the increased length will be approximately equal and we can form near regular k-gon. Thus we can ask, what is the minimum t so that the lengths $b_i + t$ will always form a polygon for every subset of sides $b_1, b_2, \ldots, b_k$. Experimental observation: Let s be the semiperimeter of the n-gon. If the k largest sides of the n-gon are selected then $$ t_{\min} = \frac{s(n-k)}{(k-2)(n-1)} \tag 1 $$ If we select any k side of the n-gon then $$ t_{\min} = \frac{s}{k-2} \tag 2 $$ Can these be proved or disproved? Corollary: As an example, $n=4, k=3$ implies that if a,b,c are the three largest sides of a quadrilateral whose semiperimeter is s then the three numbers $$ a + \frac{s}{3}, \quad b + \frac{s}{3}, \quad c + \frac{s}{3} $$ always satisfy the triangle inequality even if a,b,c do not but with any quantity lesser than $\displaystyle \frac{s}{3}$ the triangle inequality may fail.

Does $\sum_{n=0}^{\infty}\frac{(4n)!^2}{2^{8n}(n+1)^2(2n)!^4}$ have the proposed closed form?

Context While working with the $_4F_3(a,b,c,d;e,f,g;x)$ I arrived to: $$S=\frac{64}{9}\left(\hspace{.1cm} _4F_3(-\frac{3}{4},-\frac{3}{4},-\frac{1}{4},-\frac{1}{4};-\frac{1}{2},-\frac{1}{2},1;1)-1\right)=\sum_{n=0}^{\infty}\frac{(4n)!^2}{2^{8n}(n+1)^2(2n)!^4}\tag{1}.$$ Wich seems to evaluate to: $$S=\frac{16\sqrt{2}\Gamma^2{(\frac{1}{4})}}{27\pi^{3/2}}+\frac{32\sqrt{2\pi}}{3\Gamma^2{(\frac{1}{4})}}+\frac{352}{27\pi}-\frac{64}{9}\tag{2}.$$ Attempt Since it can be deduced from the Binomial Theorem: $$\sum_{n=0}^{\infty}\frac{x^{n}(4n)!}{2^{4n}(2n)!^2}=\frac{\sqrt{1+\sqrt{1-x}}}{\sqrt{2}\sqrt{1-x}},\hspace{.5cm}|x|<1.\tag{3}$$ Then integrating both sides of (3): $$\sum_{n=0}^{\infty}\frac{x^{n+1}(4n)!}{2^{4n}(n+1)(2n)!^2}=\frac{8}{3}-\frac{2\sqrt{2}(\sqrt{1-x}+1)^{3/2}}{3},\hspace{.5cm}|x|<1.\tag{4}$$ In view of the form of (1) suggests apply Parseval's Theorem to (4) when $x=-ke^{ix}$. Then: $$I(k)=\sum_{n=0}^{\infty}\left(\frac{(-k)^{n+1}(4n)!}{2^{4n}(n+1)(2n)!^2}\right)^2=\frac{1}{2\pi}\int_{-\pi}^{\pi}|\frac{8}{3}-\frac{2\sqrt{2}(\sqrt{1+ke^{ix}}+1)^{3/2}}{3}|^{2}dx.$$ I have some trouble with the last integral. Question How can we prove the proposed closed form? Thanks in advance for your efforts.

Is there a simple proof of this metric relation in this Sangaku?

Here's a sangaku problem I've been imagining but I don't know if it's already known : (ABCD) is a parallelogram whose diagonals intersection at O . If : a , b , c and d are the radii of the circles inscribed in triangles (BCD) ; (OAD) ; (OAB) and (ABC) respectively , then I conjecture the metric relation : ad = 2bc . which I was able to verify using GeoGebra by repeating the attached configuration several times. Is there a simple proof based on the basic relationships in triangles and parallelograms ? I wonder , and I'm searching

Conjecture: If a tangential quadrilateral's incenter is its lamina centroid, then it must be a kite.

For symmetry reasons it is clear that rhombi do have the "incenter = lamina centroid" property. It is also not difficult to find some special kites having this property. And here the open problem begins: I am rather sure that no other quadrilaterals can have this property. I could not find a proof (neither a geometric nor an analytic one) for the following conjecture: Conjecture: If for a tangential quadrilateral "incenter = lamina centroid" holds, it must be a kite. In other words: In the world of tangential quadrilaterals, only kites can have the property "incenter = lamina centroid". Note that rhombi are special kites. Any proof with any means welcome!

A conjecture relating consecutive prime gaps using bounded powers of two

Let p_n denote the n-th prime number. For $n \ge 3$, define the consecutive prime gaps: $$ d_n = p_n - p_{n-1} $$ $$ d_{n-1} = p_{n-1} - p_{n-2} $$ Define the finite set: $$ E_n = \{ -1, 2, 3, 5, 7, d_{n-1} \} $$ I propose the following conjecture. Conjecture For every $n \ge 3$, there exist: $\varepsilon \in \{-1, 0, 1\}$, an integer $k \in \{0, 1, 2, 3, 4, 5, 6\}$, and a subset $S \subseteq E_n$ (each element used at most once), such that the following equality holds: $$ p_n + \varepsilon = p_{n-1} + \sum_{x \in S} x + 2^k $$ Equivalently, in terms of prime gaps: $$ d_n + \varepsilon = \sum_{x \in S} x + 2^k $$ Motivation This conjecture suggests that the current prime gap d_n can always be approximated (up to ± 1) by a combination of: the previous prime gap d_{n-1}, a small fixed set of primes $\{2, 3, 5, 7\}$, and a bounded power of two. I have tested this conjecture on many small values of n and found no counterexample so far. However, I do not have a proof, nor do I know whether a counterexample exists for large n. Question Is this conjecture known to be false or incompatible with known results on prime gaps? Are there known results suggesting that such a bounded additive control of consecutive prime gaps cannot hold for all n?

Behavior of polynomial roots when removing a single term.

Now posted on MO here Let $n \in \mathbb{N}$ and let $C > 0$ be a fixed constant. Consider the class of monic polynomials of degree n with complex coefficients bounded by C: $$\mathcal{P}_n(C) = \left\{ P(z) = z^n + \sum_{j=0}^{n-1} a_j z^j \;\Bigg|\; a_j \in \mathbb{C}, \, |a_j| \le C \right\}$$ For a given polynomial $P(z) = \sum\limits_{j=0}^n a_j z^j$ (where $a_n=1$), we define a term deletion process. Let $P_k(z)$ denote the polynomial obtained by removing the k-th term of $P(z)$: $$P_k(z) = P(z) - a_k z^k \quad \text{for } k \in \{0, 1, \dots, n\}$$ Let $Z(P)$ denote the multiset of roots of a polynomial P. We are comparing the roots of the original polynomial, $Z(P)$, to the aggregate multiset of roots of all modified polynomials: $$\mathcal{Z}_{\text{mod} } = \bigcup_{k=0}^n Z(P_k)$$ Let $N_{\text{total}} = |\mathcal{Z}_{\text{mod}}|$ be the total number of roots generated by this process (counting multiplicity). For any root $\zeta \in \mathcal{Z}_{\text{mod}}$, we define its distance to the original root set as: $$\text{dist}(\zeta, Z(P)) = \min_{w \in Z(P)} |\zeta - w|$$ Proposed Property For "almost all" roots generated by term deletion, this distance becomes negligible as the degree increases. Specifically, for any fixed $\varepsilon > 0$, and for any sequence of polynomials $P^{(n)} \in \mathcal{P}_n(C)$, the proportion of modified roots that are "far" from the original roots tends to zero. Formally: $$\lim_{n \to \infty} \frac{\left| \left\{ \zeta \in \mathcal{Z}_{\text{mod}} : \text{dist}(\zeta, Z(P^{(n)})) > \varepsilon \right\} \right|}{N_{\text{total}}} = 0$$ Numerical Evidence To test the conjecture, a Python script was used with the following parameters: Inputs: Degree n and distance threshold ε. Generate a monic polynomial $P(z) = z^n + \sum_{j=0}^{n-1} a_j z^j$ is generated where each coefficient a_j is a random complex number. Output Data: The Generated Polynomial P(z) The total count of modified roots N_{total}. The count of "far" roots where $\text{dist}(\zeta, Z(P)) > \varepsilon$. Is every sufficiently large integer the sum of two semiprimes with distinct prime factors?

I have been thinking about this conjecture lately: Every sufficiently large integer n can be written in the form $$ n = p_1 \cdot p_2 + p_3 \cdot p_4 $$ where p_1, p_2, p_3, p_4 are distinct prime numbers. Obviously, we need to separate the problem into dealing with even and odd numbers. Dealing with the even numbers, Chen’s theorem proves that every sufficiently large even number can be written as the sum of a prime and a semiprime. It seems logical that sufficiently large even numbers can be written as the sum of two semiprimes, as semiprimes are more dense than primes, but is there a rigorous proof out there? In the case of the odd numbers, I am not even sure which theorem could be the key to deal with this problem. Obviously, one of the prime numbers must be 2, so the conjecture takes up this form: $n_{\text{odd}}=2\cdot p_2+p_3\cdot p_4$. I think this might be related to Goldbach’s theorem. Can anyone give me some explanation if this statement can be proven from already existing theorems? Also, if this conjecture is true, there should exist an upper bound for integers that cannot be written in this form, are there any results covering this topic? I would appreciate any help or guidance, thank you in advance for your time!

Is every sufficiently large integer is the sum of some integer n and the number of divisors of n

Is it true that $$ \forall N > N_{0}, \exists n : N = n + \tau(n) $$ where $\tau(n)$ is the number of divisors of n (with n included). I have been trying to solve that for several days without any success. I tried to use the fact that $\tau(n)$ is odd only for $n = a^2$. Also I tried to show that there are always two different numbers m and n such that $$ m + \tau(m) = n + \tau(n) $$ then we would (probably) show that there are infinitely many gaps. But I failed to prove that. First numbers which cannot be written in a such way are: 1, 3, 6, 8, 11

Bertrand's Postulate bound of $p_{n+1} \lt 2p_n$ can be lowered even further, down to $p_{n+1} \lt p_n + 2n$ - known conjecture?

Verification Code. from sympy import * def actual_count(n, x): count = 0 for a in range(prime(n) + 1, x+1): if isprime(a): count += 1 return count N = 800 for n in range(1, N+1): for x in range(1, 2*prime(n+1) + 1): A = actual_count(n, x) #F = formula(n, x) #assert A == F if A > 0: assert x <= prime(n) + 2 * n print(f"{x} <= p_{n} + 2*{n} = {prime(n) + 2 * n}") break Question. Bertrand's classical postulate implies that $p_{n+1} \lt 2p_n$ for all $n \geq 1$. Was wondering if anyone has conjectured or even proven the even sharper bound of $p_{n + 1} \lt p_n + 2n$. 3 <= p_1 + 2*1 = 4 <= 4 = 2*p_1 5 <= p_2 + 2*2 = 7 <= 6 = 2*p_2 7 <= p_3 + 2*3 = 11 <= 10 = 2*p_3 11 <= p_4 + 2*4 = 15 <= 14 = 2*p_4 13 <= p_5 + 2*5 = 21 <= 22 = 2*p_5 17 <= p_6 + 2*6 = 25 <= 26 = 2*p_6 19 <= p_7 + 2*7 = 31 <= 34 = 2*p_7 23 <= p_8 + 2*8 = 35 <= 38 = 2*p_8 29 <= p_9 + 2*9 = 41 <= 46 = 2*p_9 31 <= p_10 + 2*10 = 49 <= 58 = 2*p_10 37 <= p_11 + 2*11 = 53 <= 62 = 2*p_11 41 <= p_12 + 2*12 = 61 <= 74 = 2*p_12 43 <= p_13 + 2*13 = 67 <= 82 = 2*p_13 47 <= p_14 + 2*14 = 71 <= 86 = 2*p_14 53 <= p_15 + 2*15 = 77 <= 94 = 2*p_15 59 <= p_16 + 2*16 = 85 <= 106 = 2*p_16 61 <= p_17 + 2*17 = 93 <= 118 = 2*p_17 67 <= p_18 + 2*18 = 97 <= 122 = 2*p_18 71 <= p_19 + 2*19 = 105 <= 134 = 2*p_19 I think I can prove it using a combination of Bertrand's postulate itself and rank arguments involving a $\Bbb{Z}$-linearly independent basis of functions, which happens to be of size $2n$ functions in the basis. But that's off-topic for this site.

Monotonicity of a sequence involving alternating binomial sums and logarithms: $a_p = \frac{\pi^2}{6} + p w_p - p^2 c_p^2$

Let $p \ge 1$ be an integer. Consider the following alternating binomial sums involving logarithms: $$c_p := -\frac{1}{p} \sum_{k=1}^p (-1)^k \binom{p}{k} \ln k$$ $$w_p := -\frac{1}{p} \sum_{k=1}^p (-1)^k \binom{p}{k} (\ln k)^2$$ Using these, define the sequence $(a_p)_{p \ge 1}$ as: $$a_p := \frac{\pi^2}{6} + p w_p - p^2 c_p^2$$ Can we prove that a_p is decreasing in p? I've computationally verified this for $p<100$. I've also considered using $\binom{p+1}{k} = \binom{p}{k} + \binom{p}{k-1}$, but this makes the expressions significantly more difficult to handle. These can be in the form of the Nörlund-Rice integrals, however I don't see how to move on from there (I'm no expert in complex analysis). Please, can a wizard help me? Edit: 16/3/2026 (Thanks to Daniel Goc's suggestions) Using: $$\ln(x) = \int_0^\infty \left(\frac{1}{1+t} - \frac{1}{x+t} \right) dt$$ We can pull the discrete sums inside the integral. As discovered, this beautifully collapses the binomial expansions into a single double integral over the interval $(0, \infty)^2$: $$(p+1)(a_p - a_{p+1}) = \int_0^\infty \int_0^\infty I(s,t) \, ds \, dt$$ where for $x > 0$: $$w(x) := \frac{(p+1)!}{(x+1)(x+2)\dots(x+p+1)} \in (0,1)$$ $$I(s,t) = \frac{w(s)(1-w(t))}{t} + \frac{w(t)(1-w(s))}{s} + \frac{w(t)-w(s)}{t-s} - \frac{w(s)w(t)}{p+1}$$ Let $$g(x) := \frac{1}{w(x)} = \prod_{k=1}^{p+1} \left(1 + \frac{x}{k}\right)$$ This is a polynomial of degree $p+1$, which we can write as: $$g(x) = \sum_{n=0}^{p+1} c_n x^n$$ Note that $c_0 = 1$ and $c_1 = \sum_{k=1}^{p+1} \frac{1}{k} = H_{p+1}$ which is the $(p+1)$th harmonic number. With a bit of work, we obtain: $$I(s,t) = w(s)w(t) \left[H_p - \sum_{n=3}^{p+1} c_n \sum_{k=1}^{n-2} t^{n-1-k} s^k \right]$$ Define the k-th moment of the $w(x)$ as $M_k := \int_0^\infty x^k w(x) \, dx$, integrating our factorized $I(s,t)$ over $(0, \infty)^2$, the separability of the polynomial terms allows us to distribute the integrals: $$\begin{aligned} \int_0^\infty \int_0^\infty I(s,t) \, ds \, dt &= \int_0^\infty \int_0^\infty w(s)w(t) \left[H_p - \sum_{n=3}^{p+1} c_n \sum_{k=1}^{n-2} t^{n-1-k} s^k \right] ds \, dt \\ &= H_p \left(\int_0^\infty w(s) ds\right) \left(\int_0^\infty w(t) dt\right) - \sum_{n=3}^{p+1} c_n \sum_{k=1}^{n-2} \left(\int_0^\infty w(s) s^k ds\right) \left(\int_0^\infty w(t) t^{n-1-k} dt\right) \end{aligned}$$ This gracefully collapses the tough problem into: $$(p+1)(a_p - a_{p+1}) = H_p M_0^2 - \sum_{n=3}^{p+1} c_n \sum_{k=1}^{n-2} M_k M_{n-1-k}$$ Where our goal is to prove that: $$H_p M_0^2 > \sum_{n=3}^{p+1} c_n \sum_{k=1}^{n-2} M_k M_{n-1-k}$$ I think this is not the way.

Triangle inequality for distances from an interior point to three points on the edge of a rectangle

Definition: A closed curve S is said to have a completely triangular region if it has at least one interior point P such that for all triplets of points A,B,C on the edges of S the distances PA,PB,PC satisfy the triangle inequality. Example: For circle with radius R, its completely triangular region is a concentric circle with radius $R/3$. See proof by @lulu in the comments of this post. Question: Does a rectangle have a completely triangular region? My experimental data suggests that as a rectangle becomes thinner, its completely triangular region become smaller and at a critical point it vanishes. More specifically, Conjecture: If the ratio of the height to the width of a rectangle is greater than $\sqrt{3}$ then it has no completely triangular region. Can this be proved or disproved?

Is Euler's line tangent to the circle passing through the orthocenter and the two isogonic centers of a triangle?

By experimentations using GeoGebra and involving the two isogonic centers of triangle ABC, I observed that the circle passing through these two points, as well as through the orthocenter H of ABC, is tangent to the Euler line, precisely at H. Is this a known property, if it turns out to be true? If not, would a synthetic or computational proof be possible? Thank you for your answers and feedback.

How small is $\Pr(TU=TV)$ for a random Toeplitz matrix over $\mathbb{Z}$?

How small is $\Pr(TU=TV)$ for a random Toeplitz matrix over $\mathbb{Z}$? Let h be a large integer and let $m = \alpha h \log h$ for some constant $\alpha > 0$. Let T be a random $(0,1)$-Toeplitz matrix of size $h \times m$, obtained by choosing its $h+m-1$ diagonal entries independently and uniformly from $\{0,1\}$. Let $U, V \in \{0,1\}^m$ be independent uniform random vectors, and consider the collision probability $$ \Pr(TU = TV), $$ where the product is taken over the integers (i.e., in $\mathbb{Z}^h$). Equivalently, writing $X := U - V \in \{-1,0,1\}^m$, this is $$ \Pr(TX = 0). $$ Basic bound A simple argument shows that $$ \Pr(TU = TV) \le 2^{-h} + 2^{-m}. $$ Indeed, conditioning on $X \neq 0$, one can expose the Toeplitz diagonals sequentially and see that each of the h equations forces a fresh random bit, giving probability at most 2^{-h}. Question / conjecture I am wondering whether a much stronger bound holds on average: Are there constants $\alpha, \beta > 0$ such that for $m = \alpha h \log h$, $$ \Pr_{T,U,V}(TU = TV) \le 2^{-\beta h \log h} \, ? $$ Heuristically, for a typical X, each row $(TX)_i$ is a random signed subset sum of about $m/2$ terms, so $$ \Pr((TX)_i = 0) \approx O(m^{-1/2}), $$ and if the h constraints behaved independently one would expect $$ \Pr(TX = 0) \approx m^{-h/2} = 2^{-\Theta(h \log h)}. $$ Difficulties The main issue is that the rows of a Toeplitz matrix are highly dependent (they are shifts of each other), so standard iid Littlewood--Offord arguments do not apply directly. Moreover, the bound cannot hold uniformly over all $X \in \{-1,0,1\}^m$ (e.g., very sparse or highly structured X can give much larger probabilities), so one needs to exploit the distribution of $X = U - V$. Question Is such a bound known? Are there relevant results on anti-concentration for random Toeplitz (or convolution-type) operators that could be used here?

Validity of the conjecture $ \ln (1^{a_1} 2^{a_2} \dots n^{a_n}) = C \left (n \ln (n) - n \right) +O(\ln n)$?

Heuristic proof: Consider the integral $$ \int_{0}^{b} \ln(x) dx = b \ln b -b $$ We define $$C = \lim_{s \to 1} (\sum_{r=1}^\infty \frac{a_r}{r^s} \times \frac{1}{\zeta(s)}) $$ and the $\epsilon = b/n$ and the Riemann limit but take a weighted sum (with positve numbers a_r): $$ C \int_{0}^{b} \ln(x) dx = \lim_{n \to \infty} (a_1 \ln \epsilon + a_2 \ln (2 \epsilon) + \dots + a_n \ln (n \epsilon)) \epsilon $$ Rearraging: $$ C \int_{0}^{b} \ln(x) dx = \lim_{n \to \infty} ((\ln (1^{a_1} 2^{a_2} \dots n^{a_n}) + (\frac{\sum a_r}{n} n \ln \epsilon) \epsilon$$ Now using asymptotics and cancelling some factors and terms: $$ C \left (n \ln (n) - n \right) \sim \ln (1^{a_1} 2^{a_2} \dots n^{a_n}) $$ Conjectured Claim: For $$C = \lim_{s \to 1} (\sum_{r=1}^\infty \frac{a_r}{r^s} \times \frac{1}{\zeta(s)})\neq 0$$ the following holds: $$ \ln (1^{a_1} 2^{a_2} \dots n^{a_n}) = C \left (n \ln (n) - n \right) +O(\ln n)$$ Is this correct? Can it be proven if so?

An angle in a triangle satisfying $a^3 + b^3 = c^3$

$\triangle ABC$ is a triangle. Let $|BC|= a$; $|AC|= b$; $|AB|= c$. We know that if: $a^2 + b^2 = c^2$, then angle C is equal to 90°. So, I asked myself the following question: What happens when, instead, we have $$a^3 + b^3 = c^3?$$ I conducted many experiments with GeoGebra which allowed me to conjecture that, in this case, we necessarily have $$78° < C < 90°.$$ Is this true? If so, can we prove this inequality with, perhaps, greater precision?

Signs of polynomials in e and π

I am trying to prove this formula for all (or at least all but finitely many) n: $$ \begin{align} \tag{1} &\operatorname{sign}\!\left[\sum_{j=0}^{n+1} (-1)^j \binom{n+1}{2j} (2\pi)^{2j} \right]\\ &= \operatorname{sign}\!\left[-(e-1)^{n+1} n! + \sum_{k=0}^{n} (e-1)^{\,n-k} \sum_{j=0}^{k} (-1)^j \binom{k}{j} (k+1-j)^n \right] \end{align} $$ The LHS is a polynomial in π, let's call it $P_n(\pi)$. The RHS is a polynomial in e, say $Q_n(e)$. The full derivation is here: https://projecteuclid.org/journals/involve-a-journal-of-mathematics/volume-7/issue-1/Comparing-a-series-to-an-integral/10.2140/involve.2014.7.57.full. The polynomial in π is essentially $\cos(m \cdot \arctan(2\pi))$ scaled by a positive constant, which can be derived using Chebyshev polynomials. The polynomial in e is a negative integer order polylogarithm which can be computed explicitly using Stirling numbers of the second kind, which relates to the inclusion-exclusion principle mentioned by @ThomasAndrews. The idea for this conjecture essentially came from comparing the gamma function $\int_0^\infty t^x e^{-t}dt$ with the related sum $\sum_{k=1}^\infty k^x e^{-k}$. The difference can be written as an infinite series using the Poisson summation formula. It equals $$ \begin{align} -2 \Gamma(x+1) \cdot \sum_{k=1}^{\infty} \frac{ \cos \left((x+1)\arctan(2\pi k)\right) }{ \left(1 + 4\pi^2 k^2\right)^{(x+1)/2} } \end{align} $$ The series converges quickly, so I inserted integer values for x, truncated the sum after the first term and conjectured that this should give the correct sign (and asymptotic behaviour) of the full sum. The polynomials both change signs infinitely often (proven in the paper) and the conjecture would follow from the number $\arctan(2\pi)/\pi$ having finite irrationality measure. In the case where the irrationality measure is infinite (i.e., it's a Liouville number), the polynomial in π could come very close to zero infinitely many times which would make deciding the sign very difficult. I couldn't prove anything about the irrationality measure, however. There's one more thing I looked at, a recursion for the polynomials Q_n, defined as above (where $x=e-1$). They satisfies the recursion \begin{align} Q_{n+1}(x) &= (n+1)(x+1)\,Q_n(x) \\ &\quad - (x^2 + x)\,Q_n'(x) \\ &\quad - (n+1)!\,x^{n+2}. \end{align} This is not a linear recursion because the degree $n+1$ appears explicitely, but it still looks "rigid", in the sense that the sign sequence might be Sturmian, i.e. governed by $\cos(n\cdot c \pi)$ for fixed x and some irrational c.

Conjecture : $\forall n>2, \max_{d \mid (2^n + 3)} v_2(d+9)<3\log(n)$

Edit : $L(b,a,c)=\min(\{x>0 , a^x \equiv b \pmod c \})$ (like discrete log) Let me clarify, why discrete log shows up in this conjecture Since $d \mid 2^n+3$ we'll have $n \equiv L(-3,2,d) \pmod {\text{ord}_d(2)}$ As $n>0$, we'll have $n \ge L(-3,2,d)$ where $d=2^v\lambda-9$ for some odd integer λ So maybe using some lower bound of $L(-3,2,d)$ which involves d and hence v we'll get something like $v=O(\log(n))$, Can someone guide me toward papers involving nice estimates of L ? Let n be a positive integer , we call $\psi(n) = \max \left\{ v_2(d+9) \text{ s.t. } d \mid 2^n + 3 \right\}$ for instance : $2^8+3=7\times 37$ then $\left\{ v_2(\color{blue}d+9) \text{ s.t. } d \mid 2^8 + 3 \right\}=\{ v_2(\color{blue}1+9) , v_2(\color{blue}7+9),v_2(\color{blue}{37}+9),v_2(\color{blue}{7\times 37}+9)\}$ $=\{ 1,4,1,2 \}$, so $\psi(8)=\max\{ 1,4,1,2 \}=4$ my conjecture is : $\forall n>2 , \psi(n)<3\log(n)$ Remark: Here $\log$ denotes the natural logarithm (base e) here's a plot of $\psi(n)$ and $3\log(n)$ for $n\le300$, here's a chart of integers scattered in $\color{red}{\text{red}}$ where ψ is so big than usual, $$\psi(13)=6 < 3\log(13) \approx 7.694$$ $$\psi(22)=8 < 3\log(22) \approx 9.273$$ $$\psi(33)=10 < 3\log(33) \approx 10.489$$ $$\psi(248)=12 < 3\log(248) \approx 16.540$$ $$\psi(269)=14 < 3\log(269) \approx 16.784$$ My attempt : I found $\displaystyle \forall n >8$ we'll have $\displaystyle \psi(n)<\frac{n}{2}$, First note that , $\psi(n)≥1$ since $v_2(1+9)=1$ if $2^n+3 \in \mathbb{P}$ then $\displaystyle \forall n \ge 3 ,\psi(n)=2<\frac{n}{2}$ for $n > 4$ otherwise , take $d \mid 2^n+3$ s.t. $d<2^n+3$ and let $d=2^v\lambda-9$ where $v=v_2(d+9) \ge 1$ and λ an odd integer ≥1 since $\gcd(2^n+3,6)=1$, we'll

have $5d \le2^n+3 \implies 2^v \le 0.2\cdot2^n+9.6$ so $v \le \log_{2}\left(0.2\cdot2^{n}+9.6\right)<n$ for $n \ge 4$ thus $\forall n ≥4 , \psi(n)<n$ now note that $2^v\lambda \equiv 9 \pmod d$ and $2^n \equiv -3 \pmod d$ $\Rightarrow 2^v\lambda \equiv -3\cdot2^n \pmod d \Rightarrow 3\cdot2^{n-v}\equiv -\lambda \pmod d$ (since d is odd and $v<n$) so $2^v\lambda-9 \mid 3\cdot 2^{n-v}+\lambda$, if $2^v\lambda-9=3\cdot 2^{n-v}+\lambda$, I'll show $\displaystyle v<\frac{n}{2}$ we have : $(2^v-1)\lambda = 3(2^{n-v}+3)$ so $\lambda \mid 2^{n-v}+3$ (since $\gcd(\lambda,3)=1$) so $v_2(\lambda+9)\le\psi(n-v)<n-v$ for $n-v \ge 4$ and $2^v\lambda=\lambda+9+3\cdot2^{n-v} \Rightarrow v=v_2(\lambda+9)$ and $2^v \mid 3 \cdot 2^{n-v}$ so $2v \le n$ $\displaystyle \Rightarrow \lambda = \frac{\lambda+9}{2^v}+3\cdot2^{n-2v} \Rightarrow n-2v>0$ since λ and $\displaystyle \frac{\lambda+9}{2^v}$ are odd hence $\displaystyle v<\frac{n}{2}$, now if $n-v\le3$ we have $\lambda \mid 2^{n-v}+3$ $\displaystyle \implies \frac{2^{n-v}+3}{\lambda} \in \{ 1,5,7,11 \}$ since $2^{n-v}+3$ is prime for $n-v \le 3$ and $\displaystyle 2^v=1+\frac{3(2^{n-v}+3)}{\lambda}\le1+3\times 11=34 \Rightarrow v \le 5$ so $n \le 3+v \le 8$, but we're taking $n>8$ otherwise , $2^v\lambda-9<3\cdot 2^{n-v}+\lambda$ we will have $\displaystyle2^v\lambda-9 \le \frac{3\cdot 2^{n-v}+\lambda}{5}$, since $\gcd(3\cdot 2^{n-v}+\lambda,6)=1$ this will lead to $5X^2-46X-3\cdot 2^n \le0$ where $X=2^v$ (we got rid from λ , by using $\lambda \ge 1$) $\displaystyle \Rightarrow X \le \frac{23+\sqrt{529+15\cdot2^n}}{5} \Rightarrow v \le \log_{2}\left(\frac{23+\sqrt{529+15\cdot2^{n}}}{5}\right)<\frac{n}{2}$, for $n \ge 10$ and $\psi(9)=4<4.5 , \psi(10)=3 <5$ so we can take $n>8$ Thus $\displaystyle \forall n >8 , \psi(n) < \frac{n}{2}$ some further questions : Can we further optimize our estimate to ψ ? If so how can we do it ? How far can we generalize this to estimate valuations of shifted divisors ?

Conjecture: The probability that a line through two random points in a prism with convex bases intersects neither base is 1/2.

A line passes through two uniformly random points inside a prism with convex bases. Here is an example with triangular bases. Is the following conjecture true: The probability that the line intersects neither base is $1/2$. I have proven that if the bases are circles, the probability is $1/2$. Simulations suggest that if the bases are triangles or rectangles, the probability is also $1/2$. I am hoping for an intuitive proof based on symmetry, but any proof will be appreciated. (If an intuitive explanation cannot be found, I will add this question to the list.)

A conjecture concerning three-way number partitioning

To start with, apologies for the length of this posting. I have a conjecture that I am interested in proving or disproving. Before I get to the conjecture, I need a fair amount of background material. The starting point for the situation is a multiset of n non-negative ordered numbers: \begin{equation} x_{1} \, \ge \, x_{2} \, \ge \, \ldots \, \ge x_{n} \, > \, 0 \; . \tag{1} \end{equation} I assume $n \ge 4$. I want to partition these numbers into 3 subsets. I will represent this partition by an ordered triplet of the indices $\{1,2, \ldots n\}$: \begin{equation} T \, = \ (P(1), P(2), P(3)) \, . \tag{2} \end{equation} As this is a partition, it has the following two properties: \begin{equation} P(1) \, \cup \, P(2) \, \cup \, P(3) \, = \, \{1, 2, \ldots \, n \} \quad \text{and} \quad P(i) \cap P(j) \, = \, \emptyset, \, i \ne j \tag{3} \end{equation} To prevent repeated partitions, I require the following montonicity property: Monontonic partition A partition will be monotonic when the smallest element in $P(i)$ is always less than the smallest element in $P(j)$, when $i < j$. There are three pairs of subsets that I am interested in: \begin{equation} \Psi \, = \, \{ (1,2), (2,3), (1,3) \} \; . \tag{4} \end{equation} Given a subset $P \subset \{1, 2, \, \ldots \, n\}$, I will use the shorthand $S(P)$ to represent the following sum: \begin{equation} S(P) \, = \, \sum_{i \in P} \, x_{i} \; . \tag{5} \end{equation} I am interested in the following three differences: \begin{equation} D(i,j) \, = \, S(P(i)) - S(P(j))\, = \, \sum_{r\in P(i)} x_{r} \, - \, \sum_{r\in P(j)} x_{r}, \; (i,j) \in \Psi . \tag{6} \end{equation} The objective in considering partitions is to minimize the largest absolute value of the three $D(i,j)$ differences: \begin{equation} J(P(1), P(2), P(3)) \, = \, \max\{ |D(i,j)| \, : \, (i,j) \in \Psi \} \; . \tag{7} \end{equation} In general, without knowing the x_{i}, I cannot know beforehand whether a difference $D(i,j)$ will be positive or negative. However, there is a class of differences, which I call assurdely non-negative (ANN), which can never be negative. ANN difference A difference $D(i,j)$ is assuredly non-negative (ANN), when $D(i,j) \ge 0$, regardless of the x_{i} values. There are conditions that are reasonably easy to compute for testing whether a $D(i,j)$ is ANN or not. (See https://math.stackexchange.com/a/5106854.) Correspondingly, I define an ANN partition. ANN partition A partition $(P(1), P(2), P(3))$ will be called an ANN partition when at least one of the differences $(D(1,2), D(2,3), D(1,3))$ is ANN. Given two partitions $(\bar{P}(1), \bar{P}(2), \bar{P}(3))$ and $(\hat{P}(1), \hat{P}(2), \hat{P}(3))$, it is possible that one dominates the other. Domination Let $(\hat{P}(1), \hat{P}(2), \hat{P}(3))$ and $(\bar{P}(1), \bar{P}(2), \bar{P}(3))$ be two partitions for which it can be proved that $J(\hat{P}(1), \hat{P}(2), \hat{P}(3))$ $\le$ $J(\bar{P}(1), \bar{P}(2), \bar{P}(3))$, regardless of the x_{i} numbers. In such a case I say that partition $(\hat{P}(1), \hat{P}(2), \hat{P}(3))$ dominates partition $(\bar{P}(1), \bar{P}(2), \bar{P}(3))$. Consider two partitions, $\bar{T} = (\bar{P}(1), \bar{P}(2), \bar{P}(3))$ and $\hat{T} = (\hat{P}(1), \hat{P}(2), \hat{P}(3))$, whose associated differences are $\bar{D}(i,j)$ and $\hat{D}(i,j)$ respectively. Partition $\bar{T}$ will be dominated by partition $\hat{T}$, when for each $\hat{D}(i,j), (i,j) \in \Psi$, the following two conditions are met: domination condition when $\hat{D}(i, j) \ge 0$: There exists $(k,\ell) \in \Psi$ such that $\bar{D}(k,\ell) - \hat{D}(i, j)$ is ANN or there exists $(p,q) \in \Psi$ such that $-\hat{D}(i, j) - \bar{D}(p,q)$ is ANN. domination condition when $\hat{D}(i, j) < 0$: There exists $(r,s) \in \Psi$ such that $\bar{D}(r,s) + \hat{D}(i, j)$ is ANN or there exists $(t,u) \in \Psi$ such that $\hat{D}(i, j) - \bar{D}(t,u)$ is ANN. For any given n, the following is an ANN partition, which I will call the base ANN partition:

\begin{equation} P(1) = \{1\}, \quad P(2)= \{2\}, \quad P(3)) = \{3,4, \, \ldots \, n \} \, . \tag{8} \end{equation} For the base partition, the difference $D(1,2) = x_{1} - x_{2}$ is ANN. I believe that I have been able to prove the following: Proposition 1 Apart from the base ANN partition (8), all other ANN partitions are dominated. What I wish to prove/disprove is the following: Conjecture 1 For a partition $(P(1), P(2), P(3))$ to be dominated, at least one of the differences $D(i,j), (i,j) \in \Psi$, must be ANN. In other words, a necessary condition for a partition to be dominated is that it is an ANN partition. I have tested computationally the conjecture and have found it to be true for $5 \le n \le 12$. Example The following table contains three monotonic partitions for $n=6$ and their corresponding differences $D(i,j)$: \begin{equation*} \begin{array}{c|ccc} \text{item} & \text{partition } T_{1} & \text{partition } T_{2} & \text{partition } T_{3} \\ \hline P(1) & \{1,6 \} & \{ 1,6 \} & \{1 \} \\ P(2) & \{2, 3 \} & \{2, 5 \} & \{2, 5 \} \\ P(3) & \{4, 5 \} & \{3, 4 \} & \{3, 4, 6 \} \\ D(1,2) & x_{1} - x_{2} - x_{3} + x_{6} \quad \quad & x_{1} - x_{2} - x_{5} + x_{6} \quad \quad & x_{1} - x_{2} - x_{5} \\ D(2,3) & x_{2} + x_{3} - x_{4} - x_{5} \quad \quad & x_{2} - x_{3} - x_{4} + x_{5} \quad \quad & x_{2} - x_{3} - x_{4} + x_{5} - x_{6}\\ D(1,3) & x_{1} - x_{4} - x_{5} + x_{6} \quad \quad & x_{1} - x_{3} - x_{4} + x_{6} \quad \quad & x_{1} - x_{3} - x_{4} - x_{6} \\ D(i,j) \text{ that are ANN} & D(2,3) & \text{--} & \text{--} \end{array} \end{equation*} Of these three, only T_{1} is an ANN partition. Let $D_{k}(i,j)$ be a difference associated with partition T_{k}. The following table contains the inequalities showing that T_{2} dominates T_{1}: \begin{equation*} \begin{array}{c|c} \text{$D_{2}(i,j)$ that determines } J(T_{2}) & \text{ANN showing } J(T_{2}) \le J(T_{1}) \\ \hline J(T_{2}) = |D_{2}(1,2)|, D_{2}(1,2) \ge 0 & D_{1}(1,3) - D_{2}(1,2) \, = \, x_{2} - x_{4} \ge 0 \\[1ex] J(T_{2}) = |D_{2}(1,2)|, D_{2}(1,2) < 0 & D_{2}(1,2) - D_{1}(1,2) \, = \, x_{3} - x_{5} \ge 0\\[1ex] J(T_{2}) = |D_{2}(2,3)|, D_{2}(2,3) \ge 0 & D_{1}(2,3) - D_{2}(2,3) \, = \, 2x_{3} - 2x_{5} \ge 0\\[1ex] J(T_{2}) = |D_{2}(2,3)|, D_{2}(2,3) < 0 & D_{2}(2,3) + D_{1}(2,3) \, = \, 2x_{2} - 2x_{4} \ge 0 \\[1ex] J(T_{2}) = |D_{2}(1,3)|, D_{2}(1,3) \ge 0 & D_{1}(1,3) - D_{2}(1,3) \, = \, x_{3} - x_{5} \ge 0\\[1ex] J(T_{2}) = |D_{2}(1,3)|, D_{2}(1,3) < 0 & D_{2}(1,3) - D_{1}(1,2) \, = \, x_{2} - x_{4} \ge 0 \end{array} \end{equation*} To show that T_{2} does not dominate T_{3}, I can show that when $J(T_{2}) = |D_{2}(1,2)|$ and $D_{2}(1,2) \ge 0$, none of the six possible expressions given in the conditions for domination are ANN. \begin{equation*} \begin{array}{c|cc} D_{3}(i,j) & D_{3}(i,j) - D_{2}(1,2) & -D_{3}(i,j) - D_{2}(1,2) \\ \hline D_{3}(1,2) & - x_{6} & - 2x_{1} + 2x_{2} + 2x_{5} - x_{6} \\[1ex] D_{3}(2,3) & -x_{1} + 2x_{2} - x_{3} - x_{4} + 2x_{5} - 2x_{6} & -x_{1} + x_{3} + x_{4} \\[1ex] D_{3}(1,3) & x_{2} - x_{3} - x_{4} + x_{5} - 2x_{6} & -2x_{1} + x_{2} + x_{3} + x_{4} + x_{5} \end{array} \end{equation*} Using a similar argument one can show that T_{3} does not dominate T_{2}. For example, it is possible to show that when $J(T_{3}) = |D_{3}(1,2)|$ and $D_{2}(1,2) < 0$, none of the six possible expressions given in the conditions for domination are ANN. EDIT I supply here some progress that I have made. I will start here with one particular case that is indicative of my difficulties. If you are interested in how I arrived at this case, then read until the end. I start with partitions $\hat{T} = (\hat{P}(1), \hat{P}(2), \hat{P}(3))$ and $\bar{T} = (\bar{P}(1), \bar{P}(2), \bar{P}(3))$ and their associated differences $\hat{D}(i,j)$ and $\bar{D}(i,j)$. Given that both $\hat{T}$ and $\bar{T}$ are non-ANN partitions, I want to prove that it is not possible to satisfy the following six conditions: \begin{equation*} \begin{split} \gamma_{84} \, = \, \{ \bar{D}(1,2) \ge_{ANN} \hat{D}(1,2), \quad \bar{D}(1,2) \ge_{ANN} \hat{D}(2,3), \quad \bar{D}(1,2) \ge_{ANN} \hat{D}(1,3), \\ \hat{D}(1,2) \ge_{ANN} \bar{D}(2,3), \quad \hat{D}(2,3) \ge_{ANN} \bar{D}(2,3), \quad \hat{D}(1,3) \ge_{ANN} \bar{D}(2,3) \} \end{split} \end{equation*} (The notation $A \ge_{ANN} B$ means $A-B$ is ANN.) Now for the details. Suppose we are considering the conditions for which $\hat{T}$ dominates $\bar{T}$. Since we cannot assume that any difference is ANN, to fulfill the domination conditions given in the original posting, we must consider the following 6 cases: \begin{equation*} \begin{array}{ccc} \text{(a)} \, \hat{D}(1,2) \ge 0 \quad \quad & \text{(b)} \, \hat{D}(1,2) < 0 \quad \quad & \text{(c)} \, \hat{D}(2,3) \ge 0 \quad \quad \\ \text{(d)} \, \hat{D}(2,3) < 0 \quad \quad & \text{(e)} \, \hat{D}(1,3) \ge 0 \quad \quad & \text{(f)} \, \hat{D}(1,3) < 0 \quad \quad \end{array} \end{equation*} The six possible conditions that ensure that $\hat{D}(1,2)$ will dominate some difference from partition $\bar{T}$ in case (a) are the following: \begin{equation*} \begin{split} \{\bar{D}(1,2) \ge_{ANN} \hat{D}(1,2), \quad \bar{D}(2,3) \ge_{ANN}\hat{D}(1,2), \quad \bar{D}(1,3) \ge_{ANN} \hat{D}(1,2), \\ -\bar{D}(1,2) \ge_{ANN} \hat{D}(1,2), \quad -\bar{D}(2,3) \ge_{ANN}\hat{D}(1,2), \quad -\bar{D}(1,3) \ge_{ANN} \hat{D}(1,2) \} \end{split} \end{equation*} (The notation $A \ge_{ANN} B$ means $A-B$ is ANN.) Of these 6, the following can never be satisfied: \begin{equation*} \begin{split} \bar{D}(2,3) \ge_{ANN}\hat{D}(1,2), \quad -\bar{D}(1,2) \ge_{ANN} \hat{D}(1,2), \\ -\bar{D}(2,3) \ge_{ANN}\hat{D}(1,2), \quad -\bar{D}(1,3) \ge_{ANN} \hat{D}(1,2) \end{split} \end{equation*} Consider condition $\bar{D}(2,3) \ge_{ANN}\hat{D}(1,2)$. In the difference $\bar{D}(2,3) - \hat{D}(1,2)$, the first nonzero will be $-x_{1}$, owing to the monotonicity of the partitions. As such, $\bar{D}(2,3) -\hat{D}(1,2)$ can never be ANN. Similar arguments apply for the other impossible conditions. After removing the 4 conditions that cannot be satisfied, we are left with two valid conditions for case (a): \begin{equation*} \Phi(\text{a}) \, = \, \{\bar{D}(1,2) \ge_{ANN} \hat{D}(1,2), \quad \bar{D}(1,3) \ge_{ANN} \hat{D}(1,2) \} \end{equation*} The corresponding condition sets for cases (b), (c), (d), (e) and (f) are as follows: \begin{equation*} \Phi(\text{b}) \, = \, \{\bar{D}(1,2) \ge_{ANN} \hat{D}(2,3), \quad \bar{D}(2,3) \ge_{ANN} \hat{D}(2,3), \quad \bar{D}(1,3) \ge_{ANN} \hat{D}(2,3) \} \end{equation*} \begin{equation*} \Phi(\text{c}) \, = \, \{\bar{D}(1,2) \ge_{ANN} \hat{D}(1,3), \quad \bar{D}(1,3) \ge_{ANN} \hat{D}(1,3) \} \end{equation*} \begin{equation*} \begin{split} \Phi(\text{d}) \, = \, \{\bar{D}(1,2) \ge_{ANN} -\hat{D}(1,2), \quad \bar{D}(2,3) \ge_{ANN}-\hat{D}(1,2), \quad \bar{D}(1,3) \ge_{ANN} -\hat{D}(1,2), \\ \hat{D}(1,2) \ge_{ANN} \bar{D}(1,2), \quad \hat{D}(1,2) \ge_{ANN} \bar{D}(2,3), \quad \hat{D}(1,2) \ge_{ANN} \bar{D}(1,3) \} \end{split} \end{equation*} \begin{equation*} \begin{split} \Phi(\text{e}) \, = \, \{\bar{D}(1,2) \ge_{ANN} -\hat{D}(2,3), \quad \bar{D}(2,3) \ge_{ANN}-\hat{D}(2,3), \\ \bar{D}(1,3) \ge_{ANN} -\hat{D}(2,3), \quad \hat{D}(2,3) \ge_{ANN} \bar{D}(2,3) \; \} \end{split} \end{equation*} \begin{equation*} \begin{split} \Phi(\text{f}) \, = \, \{\bar{D}(1,2) \ge_{ANN} -\hat{D}(1,3), \quad \bar{D}(2,3) \ge_{ANN}-\hat{D}(1,3), \quad \bar{D}(1,3) \ge_{ANN} -\hat{D}(1,3), \\ \hat{D}(1,3) \ge_{ANN} \bar{D}(1,2), \quad \hat{D}(1,3) \ge_{ANN} \bar{D}(2,3), \quad \hat{D}(1,3) \ge_{ANN} \bar{D}(1,3) \} \end{split} \end{equation*} To obtain all possible combinations of conditions ensuring that $\hat{T}$ dominates $\bar{T}$, we simply form the Cartesian product of these condition sets: \begin{equation*} \Gamma \, = \, \Phi(\text{a}) \, \times \, \Phi(\text{b})\, \times \, \Phi(\text{c}) \, \times \, \Phi(\text{d}) \, \times \, \Phi(\text{e}) \, \times \, \Phi(\text{f}) \; . \end{equation*} In total Γ contains $2 \cdot 3 \cdot 2 \cdot 6 \cdot 4 \cdot 6 = 1728$ tuples. One such tuple is the

following: \begin{equation*} \begin{split} \gamma_{1} \, = \, \{ \bar{D}(1,2) \ge_{ANN} \hat{D}(1,2), \quad \bar{D}(1,2) \ge_{ANN} \hat{D}(2,3), \quad \bar{D}(1,2) \ge_{ANN} \hat{D}(1,3), \\ \bar{D}(1,2) \ge_{ANN} -\hat{D}(1,2), \quad \bar{D}(1,2) \ge_{ANN} -\hat{D}(2,3), \quad \bar{D}(1,2) \ge_{ANN} -\hat{D}(1,3) \} \end{split} \end{equation*} We can express the first and the fourth of these as two ANN expressions: \begin{equation*} \bar{D}(1,2) - \hat{D}(1,2) \; \text{is ANN and } \, \bar{D}(1,2) + \hat{D}(1,2) \; \text{is ANN} \; . \end{equation*} The sum of any two ANN expressions is also an ANN expression. Hence, from the sum of these two we can conclude that $2\bar{D}(1,2)$ (or simply $\bar{D}(1,2)$) is an ANN expression. However, this contradicts the assumption that all $\bar{D}(i,j)$ are non-ANN. Hence, the conditions in γ_{1} can never result in partition $\hat{T}$ dominating $\bar{T}$. The contradiction obtained for tuple γ_{1} is only one of many possible contradictions. I have written messy code to test all 1728 condition tuples for such types of contradictions. Of the 1728 tuples, 1717 yield contradictions that I can detect. However, I cannot produce contradictions for the remaining 11 condition tuples. One of these remaining 11 tuples is what I provided above: \begin{equation*} \begin{split} \gamma_{84} \, = \, \{ \bar{D}(1,2) \ge_{ANN} \hat{D}(1,2), \quad \bar{D}(1,2) \ge_{ANN} \hat{D}(2,3), \quad \bar{D}(1,2) \ge_{ANN} \hat{D}(1,3), \\ \hat{D}(1,2) \ge_{ANN} \bar{D}(2,3), \quad \hat{D}(2,3) \ge_{ANN} \bar{D}(2,3), \quad \hat{D}(1,3) \ge_{ANN} \bar{D}(2,3) \} \end{split} \end{equation*} Note that from the conditions in γ_{84}, it is straightforward to obtain $\bar{D}(1,2) \ge_{ANN} \bar{D}(2,3)$. Several non-ANN partitions exist satisfying this. Here is one example: \begin{equation*} \bar{T}_{84} \, = \, (\bar{P}(1), \bar{P}(2), \bar{P}(3)) \, = \, (\{1, 2 \}, \; \{3, 6, 9 \}, \; \{4, 5, 7, 8 \} \,) \end{equation*} However, I repeat that partition $\bar{T}_{84}$ does not dominate any other non-ANN partition.

Conjecture: Is $n = 9$ the only positive integer for which both $2^n + n^2$ and $2^n - n^2$ are prime?

Conjecture. The only positive integer n such that both $2^n + n^2$ and $2^n - n^2$ are prime is $n = 9$. For $n = 9$: $$2^9 + 9^2 = 512 + 81 = \mathbf{593} \quad \text{(prime)}$$ $$2^9 - 9^2 = 512 - 81 = \mathbf{431} \quad \text{(prime)}$$ Computational Evidence I have verified computationally that $n = 9$ is the only solution with $n \leq 2000$. The table below shows selected candidates $n \equiv 3 \pmod{6}$ (see Corollary below for why only these need be checked): $$\begin{array}{|c|c|c|c|} \hline n & 2^n + n^2 & 2^n - n^2 & \text{Both prime?} \\ \hline 3 & 17 & -1 & - \\ 9 & 593 & 431 & \textbf{Yes} \\ 15 & 32993 & 32543 & \text{No } (32543 = 7 \times 4649) \\ 21 & 2097593 & 2096711 & \text{No } (2096711 = 641 \times 3271) \\ \hline \end{array}$$ Modular Restrictions Claim 1. If n is even and $n \geq 2$, then $2^n + n^2$ is composite. Proof. For even $n = 2k$ with $k \geq 1$, we have $2^n = 4^k$ and $n^2 = 4k^2$, so: $$2^n + n^2 = 4\!\left(4^{k-1} + k^2\right)$$ which is divisible by 4 and greater than 4. $\blacksquare$ Claim 2. If n is odd and $3 \nmid n$, then $3 \mid 2^n + n^2$. Proof. For odd n, we have $2^n \equiv 2 \pmod{3}$. If $3 \nmid n$, then $n^2 \equiv 1 \pmod{3}$. Thus: $$2^n + n^2 \equiv 2 + 1 \equiv 0 \pmod{3}$$ The only case where $2^n + n^2 = 3$ would require $n = 1$, but $2^1 - 1^2 = 1$ is not prime. $\blacksquare$ Corollary. Any solution must satisfy $n \equiv 3 \pmod{6}$. This reduces the search space by a factor of 6. Heuristic Argument For candidates $n \equiv 3 \pmod{6}$, both $2^n + n^2$ and $2^n - n^2$ are approximately 2^n. By the Prime Number Theorem, a number near 2^n is prime with probability $\sim \dfrac{1}{n \ln 2}$. Assuming independence, the probability that both are simultaneously prime is roughly $\dfrac{1}{(n \ln 2)^2}$. Summing over all remaining candidates: $$\sum_{\substack{n \,\equiv\, 3 \pmod{6} \\ n \,>\, 9}} \frac{1}{(n \ln 2)^2} \approx 0.054$$ Since this series converges and the expected number of solutions beyond $n = 9$ is well below 0.06, heuristically we expect at most finitely many solutions - and quite possibly none. Questions Can we prove that $n = 9$ is the only solution? Is there a theoretical obstruction - such as a covering congruence system - that rules out all $n \equiv 3 \pmod{6}$ beyond $n = 9$? Is there a larger solution? The heuristic suggests any additional solution would be a rare exception. Does this problem appear in the literature? It seems natural but I have not found it in standard references on exponential Diophantine equations involving primes. Pointers to related work would be welcome.

Finding the solution for a problem on game between 2 players on colouring a Polygon from SMMC 2017 Session A

The Problem Let us take a regular n-sided polygon, $n \geq 3$, drawn on a piece of paper with all its vertices connected. Two people play a game in which they take turns to colour one of these line segments. Here we consider only the lines between any vertices of this n-sided polygon to be a line segment, i.e., the player can only colour a full diagonal or a full side and not just a segment formed due to the intersection of the diagonals in the polygon. The first player colours line segments blue, while the second player colours line segments red. A player cannot colour a line segment that has already been coloured. A player wins if they are the first to create a triangle in their own colour, whose three vertices are also vertices of the regular pentagon. The game is declared a draw if all ten line segments have been coloured without a player winning. Determine whether the first player, the second player, or neither player can force a win. Comment The original problem only talked about a pentagon, but an interesting variation was put up in the comments of the original's solution, and I found myself with 3 conjectures that are potentially the solution that I cannot think of an approach to prove or, find a way or an example to use to disprove them. Definition(not part of the problem) Before the conjecture, I want to put up 2 definitions that I can reuse in the conjecture: If a player, in his consecutive turns colours 2 line segments that do not share a vertex, that may or may not be intersecting, then let such a sequence of moves be called the 'Duo move'. If a player, in his consecutive turns colours 3 line segments that share 1 single vertex, then let such a sequence of moves be called the 'Trio move'. The Conjectures So here are the conjectures: For all $n \geq 5$, n-sided polygons, the first player can always force a win. Any player who can make the duo move or a trio move first can force a win. For all $n \leq 4$, n-sided polygons, neither player can force a win. My Reasoning for the Cojectures Algorithm for forced wins: For the Duo Move: When we make a duo move, we, as the first player, will have 2 common lines that connect the lines we have already covered as options

for our third turn. So even if the opponent colours one of our options, we will have the third line. And when we colour one of the uncoloured lines, we will have 2 triangles that can be completed with one more turn on the next move, thus forcing a win. However this is only in the case of $n \geq 5$. When we make a trio move, however, it is quite obvious with the following images, as it has been taken from the SMMC solutions page for the pentagon. As you can see, when a trio move happens, we will have 2 triangles forming for us on the next turn, even if one of the three possible triangles due to the 3 covered lines is covered by our opponent. More Comments This is a problem in the Question Paper of the Simon Marais Mathematics Competition 2017, and I came up with these conjectures while solving the problem, and I need help finding a proper proof, or maybe a proper disproof of them.

$\displaystyle \sum_{k=1}^n\mu(k)x^k+1$ is irreducible over $\mathbb{Q}$ iff $M(n)\not=-1$?

Let $n>0$, $\displaystyle M(n)=\sum_{k=1}^n \mu(k)$ where $\mu(k)$ is the Möbius function I was looking for values of n where $P_n(x)=\displaystyle \sum_{k=1}^n\mu(k)x^k+1$ is reducible over $\mathbb{Q}$, using PARI-GP for(n=1,100,l=polisirreducible(sum(k=1,n,moebius(k)*x^k)+1);if(l==0,print(n))) I found $3, 4, 6, 10, 15, 16, 22, 26, 27, 28, 35, \cdots$ which matches exactly the solutions to the equation $M(n) = -1$ Clearly If $M(n)=-1$, $\displaystyle P_n(1)=\sum_{k=1}^n\mu(k)+1=-1+1=0$ so P_n is reducible over $\mathbb{Q}$ but can you show the other way ? In general, how to deal with such similar polynomials like $\displaystyle\sum_{k=0}^nf(k)x^k$ where $f(k)$ is an arithmetic function like $\mu(k),\varphi(k),\chi(k),\cdots$? Thanks for help !

Proving exact formula of a coefficient

Let $$ P_n(X)=\prod_{\substack{\mu_1,\dots,\mu_n\in\{\pm1\}\\ \mu_1\cdots \mu_n=1}} \left(X-\sum_{k=1}^n \mu_k e^{k\pi i/n} \right) $$ be a polynomial of degree $d=2^{n-1}$. Let c_n'' be the coefficient in degree $d-2n$ of P_n. Conjecture. For every $n\ge 4$, $$c_n'' = (-1)^{n+1} 2^{2n-3} \left((n-1)!\right)^2 - \frac{2^{3n-3}(2^{2n}-1)B_{2n}}{n}$$where B_{2n} is the Bernoulli number with $B_2=1/6$. This answer proved $\nu_2(c''_n)\ge 6$, leaving the proof of $c_n'' \neq 0$ open, but validating this conjectured formula would help to show that $c_n'' \neq 0$.

About proof by contradiction of Morley's theorem in Euclidean geometry

I try to find a proof using ad absurdum of Morley's Miracle but find any. I tried also the conjecture : Let ABC be a triangle with angles 3α, 3β, 3γ, and let D, E, F be the intersections of its adjacent trisectors. Let ℓ be any line in the plane. Denote by (D^*, E^*, F^*) the image of (D, E, F) under Steiner symmetrization of DEF with respect to ℓ. Then the lines AD^*, BD^*, CE^*, AE^*, BF^*, CF^* are trisectors of the angles of ABC if and only if ℓ is an axis of symmetry of DEF. But cannot give a response to it . Some remarks : The map $z \mapsto z^3$ on the unit circle, viewed as a three-sheeted covering, has as its ramification curve (in the real plane) a limaçon of Pascal. The Steiner inellipse is to $z \mapsto z^2$ what Morley's triangle is to $z \mapsto z^3$: in both cases, the limaçon of Pascal is the transition curve that encodes the covering. Currently there a path to the Last Fermat theorem. $x^{2/3}+y^{2/3}=1$ The conjecture uses implicitly Morley's theorem. When a line (d) passes through the orthocenter (H) of a triangle, the orthopole (C) of (d), reflected with respect to (d), belongs to the nine-point circle. In this case, the lines joining (H) to the reflections of the vertices with respect to (d) meet the corresponding sides at three points which lie on a line (l) passing through (K). The point (K) is the projection of the circumcenter onto (d). The perpendicular drawn from (H) to (d) meets the circumcircle at two points; one of these points is the focus of the inscribed parabola tangent to (d). If, through the other point, one draws a line parallel to (d), then the reciprocal transversal of the resulting line passes through the point (A). Last page. Do there exist finitely many primes p such that there exists $k \in [1,p]$ with $\mathrm{ord}_p(k) = q$ such that $k^{p-1} \equiv 1 \pmod{p^2}$?

This is extended computational evidence for the Conjecture from this question, focusing on the $n=1$ case. Conjecture A for $n=1$ states: for all sufficiently large primes p with $q \mid p-1$, $$v_p\!\left(\prod_{k=1}^{p} \Phi_q(k)\right) = q-1.$$ Reduction to $v_p(k^{p-1}-1)$. By the Proposition in the linked question, the product receives p-adic contribution only from terms where $\mathrm{ord}_p(k) = q$, and for such k, $v_p(\Phi_q(k)) = v_p(k^{p-1}-1)$. There are exactly $q-1$ residue classes of order q mod p, each appearing exactly once in $[1,p]$, so $$v_p\!\left(\prod_{k=1}^{p}\Phi_q(k)\right) = \sum_{\substack{k=1 \\ \mathrm{ord}_p(k)=q}}^{p} v_p(k^{p-1}-1).$$ Now each term

is at least 1 by Fermat, giving the lower bound at least $q-1$. The conjecture says that for all sufficiently large p, every term is exactly 1 - which is to say no $k \in [1,p]$ with $\mathrm{ord}_p(k) = q$ satisfies $k^{p-1} \equiv 1 \pmod{p^2}$. We therefore check the following equivalent conjecture: For a fixed prime q and sufficiently large primes p, there exists no $k \in [1,p]$ such that $\mathrm{ord}_p(k) = q$ and $k^{p-1} \equiv 1 \pmod{p^2}$. Computational results. We searched all primes $p \equiv 1 \pmod{q}$ up to 10^{12} (for $q=11$) and 10^{11} (for $q=3$): $q=3$: no violations found. $q=11$: two violations, $p = 400263469$ with witness $k = 160169173$, and $p = 9544876463$ with witness $k = 3519317465$. No violations for $p > 9544876463$ up to 10^{12}, consistent with these being the finitely many exceptions below the "sufficiently large" threshold. Heuristic. The probability that a given k of order q satisfies $k^{p-1}\equiv 1\pmod{p^2}$ is heuristically $1/p$. Summing over all $q-1$ such k and all primes $p\leq X$, $$\mathbb{E}[\#\text{ violations up to }X] \;\approx\; \ln\ln X.$$ At $X=10^{12}$: predicted ≈ 3.3, observed 2 for $q=11$. This is the direct analogue of classical Wieferich primes, where only $p=1093$ and $p=3511$ would be known below 6.7×10^{15}. Sharpness. Allowing $k\leq p^{3/2}$ instead of $k\leq p$, violations become dense: a search over $p\in[10^6,10^8]$ finds 1271 violations for $q=3$ and 1100 for $q=11$. The $O(p)$ threshold is sharp. Question. For $q=11$, would $p = 400263469$ and $p = 9544876463$ be the only primes for which some $k \in [1,p]$ with $\mathrm{ord}_p(k) = 11$ satisfies $k^{p-1} \equiv 1 \pmod{p^2}$? More generally, for any fixed prime q, is the set of such exceptional primes finite? Remark. Our conjecture is logically independent of the classical Wieferich problem. For a fixed base $a > 1$, it is an open question whether there are infinitely many primes p with $a^{p-1} \equiv 1 \pmod{p^2}$; the heuristic predicts infinitely many but only finitely many are known for any base. Our conjecture makes no claim about any fixed base. Instead, for each prime p, we ask about the $q-1$ values of $[1,p]$ of order q mod p - a set of bases that changes entirely with p. Whether infinitely or finitely many primes p are Wieferich for some fixed k has no bearing on whether, for large p, the order-q elements of $[1,p]$ happen to include a Wieferich witness. The quantifier structures are different: the Wieferich problem fixes k and varies p; our conjecture fixes p and asks about all $k \in [1,p]$ of a given order simultaneously. Remark (sharpness of the $[1,p]$ threshold). The bound $k \leq p$ in the Conjecture is not arbitrary. The following computational data for $q=11$ shows a sharp transition precisely at $k = p$: For $k \in [1, p]$: searching all $p \equiv 1 \pmod{11}$ up to 10^{12}, only two violations appear, both at $p < 10^{10}$. No violations for $p > 9544876463$. For $k \in [1, p^{11/10}]$: four violations appear in $p \in [10^8, 10^{10}]$, including new ones at $p = 1788375733$ and $p = 8960980403$ that do not violate the Conjecture since $k > p$. For $k \in [1, p^{3/2}]$: 1100 violations in $p \in [10^6, 10^8]$. So violations are essentially absent inside $[1,p]$ for large p, appear almost immediately once k is allowed to exceed p, and become dense at $k \leq p^{3/2}$. The $O(p)$ threshold captures something structurally real, not a coincidence of the search range.

For which composite s does $p^k - s$ hit a prime for small prime p and integer $k\ge 1$?

Let $s \ge 4$ be a composite integer with $s \ne 0 \pmod3$. Computationally, for every such $s \le 2000$, I can find a prime p and integer $k \ge 1$ such that $p^k - s$ is prime (usually with $p \in \{2,3\}$ and small k). Heuristically this seems unsurprising: for fixed small p, the values $p^k - s$ for $k = 1,\dots,20$ give many candidates, each prime with probability $\sim\frac{1}{\log(p^k - s)}$ by PNT, so the expected number of hits is large. My question: Is this a known/named result, or a straightforward consequence of an existing theorem (e.g. related to Bateman-Horn-type heuristics for exponential sequences, or sieve methods)? I haven't found a reference for primality in sequences of the form $({p^k - s})_k$ for fixed p, only for polynomial families. Any pointers to relevant literature would be appreciated. What I've tried: exhaustive verification for $s \le 2000$, and a robustness check (no counterexamples) using digit sums of primes up to $1.5×10^{11}$, though this doesn't extend the range of s tested since digit sums grow only like $O(\log P)$.

Does every odd prime determine a prime in an interval of length $\sqrt{p-2}$?

Let $p \geq 3$ be an odd prime. I would like to know whether the following conjecture is true. Conjecture For every odd prime $p \geq 3$, there exist integers a and b such that: $a+b+3$ is prime; $4a+2b+3=p$ $\gcd(a,b,3)=1$ $b^2\leq 4a$ $a\geq 1$. Here, $\mathbb{P}$ denotes the set of prime numbers. For example: all $$(a,b,p) \in \{(4,-4,3),(1,-1,5),(2,-2,7),(2,0,11)\}$$ work. In each case, all five conditions are satisfied. Equivalent formulation as a prime in a short interval Set $$ q:=a+b+3. $$ Then q is prime. Solving the system $$ q=a+b+3 $$ and $$ p=4a+2b+3 $$ for a and b, we obtain $$ a=\frac{p-2q+3}{2} $$ and $$ b=\frac{4q-p-9}{2}. $$ Since p and q are odd primes, both a and b are integers. The inequality $$ b^2\leq 4a $$ is equivalent to $$ \left(\frac{4q-p-9}{2}\right)^2 \leq 4\left(\frac{p-2q+3}{2}\right). $$ Multiplying by 4 gives $$ \left(4q-p-9\right)^2 \leq 8\left(p-2q+3\right). $$ After simplifying, this becomes $$ \left(4q-p-7\right)^2 \leq 4\left(p-2\right). $$ Therefore, $$ -2\sqrt{p-2} \leq 4q-p-7 \leq 2\sqrt{p-2}. $$ Equivalently, $$ \frac{p+7-2\sqrt{p-2}}{4} \leq q \leq \frac{p+7+2\sqrt{p-2}}{4}. $$ Define $$ L(p):= \frac{p+7-2\sqrt{p-2}}{4} $$ and $$ U(p):= \frac{p+7+2\sqrt{p-2}}{4}. $$ The length of this interval is $$ U(p)-L(p)=\sqrt{p-2}, $$ and its midpoint is $$ \frac{p+7}{4}. $$ Thus, the conjecture is essentially equivalent to the following statement: For every odd prime $p \geq 3$, the interval $$ \left[\frac{p+7-2\sqrt{p-2}}{4}, \frac{p+7+2\sqrt{p-2}}{4} \right] $$ contains a prime. For sufficiently large p, the condition $a\geq 1$ is automatic. Indeed, $$ a=\frac{p-2q+3}{2}\geq 1 $$ is equivalent to $$ q\leq \frac{p+1}{2}. $$ For $p\geq 11$, one has $$ U(p)\leq \frac{p+1}{2}, $$ so every prime $q\in[L(p),U(p)]$ automatically gives $a\geq 1$. The cases $p=3,5,7$ can be checked directly. The condition $$ \gcd(a,b,3)=1 $$ is also automatic. If $3\mid a$ and $3\mid b$, then $$ p=4a+2b+3 $$ and $$ q=a+b+3 $$ would both be divisible by 3. Since both are prime, this would force $$ p=q=3. $$ But then

$$ a+b=0 $$ and $$ 4a+2b=0. $$ Subtracting twice the first equation from the second gives $$ 2a=0, $$ so $a=0$, contradicting $a\geq 1$. Heuristic The interval is centered near $p/4$ and has length approximately $\sqrt{p}$. The prime number theorem therefore suggests that the expected number of primes in the interval is approximately $$ \frac{\sqrt{p}}{\log p}, $$ which tends to infinity as $p\to\infty$. Cramér's conjecture would imply that every sufficiently large interval of this form contains a prime because $$ \left(\log x\right)^2=o\left(\sqrt{x}\right). $$ However, known unconditional bounds for primes in short intervals do not appear to guarantee a prime in every interval of length comparable to $\sqrt{x}$. Questions Is this conjecture already known? Can one prove unconditionally that the interval $$ [L(p),U(p)] $$ contains a prime for every odd prime p? Does the fact that p itself is prime make the problem easier than the general problem of finding primes in every interval of length comparable to $\sqrt{x}$? Does this conjecture follow from a standard conjecture weaker than Cramér's conjecture? Important: What it needs to be proven is that for all primes $p \geq 3$ the interval $[L(p), U(p)]$ contains at least one prime. However, I proved that there are infinitely many primes $p \geq 3$ such that the interval contains at least one prime in $[L(p), U(p)]$.

Possible counterexamples to Kaplansky's zero-divisors conjecture

Kaplansky's conjecture about zero divisors is formulated as follows: If G is a torsion-free group and K is a field, then the group ring $K[G]$ has no zero divisors. Some time ago, I came across the following article: В. Г. Бардаков, М. С. Петухова, “О потенциальных контрпримерах к проблеме делителей нуля”, Вестн. НГУ. Сер. матем., мех., информ., 15:3 (2015), 30-50; J. Math. Sci., 221:6 (2017), 778-797. The article talks about groups that Rips built in the hope that among them there would be a group without torsion, which would serve as a counterexample to the zero-divisor conjecture. I'll describe the construction itself here. For more detailed information, see the article. The group $G = G(\sigma, \tau, \lambda, \mu)$ is generated by $4n$, $n \geq 2$, elements $$ a_1, a_2, \dots, a_n, b_1, b_2, \dots, b_n, c_1, c_2, \dots, c_n, d_1, d_2, \dots, d_n $$ and is defined by the relations $$ a_i c_j = b_{\sigma(i,j)} d_{\tau(i,j)}, $$ $$ a_i d_j = b_{\lambda(i,j)} c_{\mu(i,j)} $$ for all (i, j) and some functions $$ \sigma, \tau, \lambda, \mu : \{1, 2, \dots, n\}^2 \to \{1, 2, \dots, n\} $$ such that their pairs $$ (\sigma, \tau), (\lambda, \mu) : \{1, 2, \dots, n\}^4 \to \{1, 2, \dots, n\}^2 $$ define bijections of the set $\{1, 2, \dots, n\}^2$, i.e., for any pair of indices (i', j') there exists a unique pair of indices (i, j) such that $i' = \sigma(i, j)$, $j' = \tau(i, j)$, and similarly for the functions (λ, μ). Then the ring $K[G]$ has zero divisors: $$ (a_1 + a_2 + \dots + a_n + b_1 + b_2 + \dots + b_n)(c_1 + c_2 + \dots + c_n - d_1 - d_2 - \dots - d_n) = 0. $$ The authors look at this class in the simplest case, $n=2$. For any n, there are $(n^2!)^2$ of such groups. The authors showed that for $n=2$, any group of this class contains a 2-torsion. They also provided a set of groups such that any group $G(\sigma, \tau, \lambda, \mu)$ is isomorphic to some group from this set. Indeed, for $n=2$, it's very easy to check for torsion. Using Tietze transformations, we eliminate the generators $$ a_1 = b_{\sigma(1,1)} d_{\tau(1,1)} c_1^{-1}, \quad a_2 = b_{\sigma(2,1)} d_{\tau(2,1)} c_1^{-1} $$ Then the group $$G(\sigma, \tau, \lambda, \mu)$$ will be generated by 6 elements $$ b_1, b_2, c_1, c_2, d_1, d_2 $$ and defined by 6 relations $$ b_{\sigma(1,1)} d_{\tau(1,1)} c_1^{-1} c_2 = b_{\sigma(1,2)} d_{\tau(1,2)}, $$ $$ b_{\sigma(2,1)} d_{\tau(2,1)} c_1^{-1} c_2 = b_{\sigma(2,2)} d_{\tau(2,2)}, $$ $$ b_{\sigma(1,1)} d_{\tau(1,1)} c_1^{-1} d_1 = b_{\lambda(1,1)} c_{\mu(1,1)}, $$ $$ b_{\sigma(1,1)} d_{\tau(1,1)} c_1^{-1} d_2 = b_{\lambda(1,2)} c_{\mu(1,2)}, $$ $$ b_{\sigma(2,1)} d_{\tau(2,1)} c_1^{-1} d_1 = b_{\lambda(2,1)} c_{\mu(2,1)}, $$ $$ b_{\sigma(2,1)} d_{\tau(2,1)} c_1^{-1} d_2 = b_{\lambda(2,2)} c_{\mu(2,2)}. $$ Next, using the SageMath package, I pretty quickly checked that a group with such relations contains torsion using the $simplified()$ function (it simplifies the presentation). In exactly the same way, by excluding a_1, a_2, a_3 in the case $n=3$, I checked a large number of these groups for torsion, and they all contained 2-torsion, but there were also groups with 3-torsion. But for larger n, I could only check random combinations, and the $simplified()$ function was getting slower and slower. All such groups contain simple torsion of the form $(xy^{-1})^2$ or $(x^{-1}y)^2$. For example, for $n=2$ consider $$σ: [2, 1, 2, 1] \quad τ: [1, 1, 2, 2] \quad λ: [1, 2, 1, 2] \quad μ: [2, 2, 1, 1]$$ For a pair of (i, j) equal to $(1, 1)$, we choose $\sigma(1, 1) = 2$, $\tau(1,1) = 1$, $\lambda(1,1) = 1$, $\mu(1,1) = 2$. For example, for $(2,1)$ we get $\sigma(2,1) = 2$, $\tau(2,1)=2$, $\lambda(2,1)=1$, $\mu(2,1) = 1$ and so for all (i, j). Functions $(i, j) \mapsto (\sigma((i, j)), \tau((i, j)))$ and $(i, j) \mapsto (\lambda((i, j)), \mu((i, j))$ are biective. Probably, in this context, it would be wiser to represent σ, τ, λ, μ as matrices of size $n \times n$, but my code works this way. Next, we build a group G with 6 generating and relations with these indices. I get $G.simplified()$ = Finitely presented group < b_1, c_1, c_2, d_1 | $(c_2^{-1}d_1)^2$, $d_1c_2^{-1}c_1d_1^{-1}c_1c_2^{-1}(d_1c_1^{-1})^2$ >. The presentation is simplified so that it always has a with torsion element. I did very little testing for $n \ge 4$, only random combinations, but almost all of them contain 2-torsion. A year ago we were discussing these examples with a friend, and he doesn't believe at all that they could provide a counterexample. Because of this, I have 2 questions: Question 1: Do you believe that among these groups there could (or could not) be a group without torsion? I'm not asking for a strict justification, any intuitive arguments are welcome. I also want to quote a question from an article posed by Roman Mikhailov: Question 2: Could there be a group among these with non-obvious torsion? (Not with torsion of the type $(xy^{-1})^k$ or $(x^{-1}y)^k$ for $k \ge 2$.)

Do first semiprime $\gcd$ occurrences have twin-prime cofactors?

Conjecture Let $S_1<S_2<S_3<\cdots$ be the sequence of semiprimes. For every prime $p\ge 5$, let k be the smallest index such that $$ \gcd(S_k,\,S_{k+1})=p. $$ Then the two cofactors are twin primes: $$ \frac{S_k}{p},\quad \frac{S_{k+1}}{p}. $$ Searching up to $S_{k+1}\le10^{14}$ gives the following results: $$ \begin{array}{|c|r|r|r|r|} \hline \large p & \large S_k & \large S_{k+1} & \large \frac{S_k}{p} & \large \frac{S_{k+1}}{p}\\ \hline 5 & 3295 & 3305 & 659 & 661\\ 7 & 15659 & 15673 & 2237 & 2239\\ 11 & 99121 & 99143 & 9011 & 9013\\ 13 & 1036061 & 1036087 & 79697 & 79699\\ 17 & 33607963 & 33607997 & 1976939 & 1976941\\ 19 & 17654933 & 17654971 & 929207 & 929209\\ 23 & 80419201 &

Does every triangle satisfy $\frac{1}{R}\left(\frac{a}{A}+\frac{b}{B}+\frac{c}{C}\right)+\frac{A^2+B^2+C^2}{\pi^2} \ge 5$

Let a, b, c be the sides of a triangle and A,B,C be the corresponding opposite angles and R be its circumradius. Experimental data shows that π^2 is the largest i.e. optimal constant for which the inequality $$ \frac{1}{R}\left(\frac{a}{A} + \frac{b}{B} + \frac{c}{C}\right) + \frac{A^2 + B^2 + C^2}{\pi^2} \ge 5. $$ for all triangles. Can this be proved? Update: We have a slightly stronger result. Let $4 <x \le 5$ then $$ \frac{1}{R}\left(\frac{a}{A} + \frac{b}{B} + \frac{c}{C}\right) + \frac{x-4}{\pi^2}\left(A^2 + B^2 + C^2\right) \ge x. $$ Related question. Update: Unfortunately, the question was closed. Reason: " ...why the question is relevant to you and our community. Some forms of context include: background and motivation, relevant definitions, source, possible strategies, your current progress, why the question is interesting or important, etc." So my honest answers are as follows: Motivation: The only motivation for me the beauty of math; I find an inequality not because I expect it to be useful or because it came out of a deeper theory etc. It may not be interesting/beautiful for some, but interest is relative and to me this is. Many of us do math just for the beauty of it, it does not have to need more motivation than this. Why is it relevant for the community: It is not a homework question; it is also not a deep research level MathOverflow type of question. It is a perfect example of a new inequality coming out of experimentation, so where else would it belong? Progress: I have discovered a plausible inequality which did not exist few hours back and I have done an extensive experimental verification. If you are of the type who only consider progress as only rigorous progress towards a proof, then I can't help it; to me experimental conjectures is also progress.

How large can the area be of a triangle whose side lengths are the angles of another triangle?

Let a,b,c be the side lengths of an acute triangle, with opposite angles A,B,C, and let K_a denote its area. Since the triangle is acute, the angles A,B,C themselves satisfy the triangle inequalities, and hence may be regarded as the side lengths of a second triangle. Let K_A denote the area of this angled triangle. This suggests the natural question: $$ \boxed{\text{How large can }K_A\text{ be relative to }K_a\text{?}} $$ More specifically, is there a sharp inequality relating the normalized areas of the original triangle and its angle triangle? Numerical evidence suggests that $$ \frac{K_A}{K_a} \le \frac{\pi^2}{(a+b+c)^2}. $$ The constant π^2 is best possible, and equality holds precisely for equilateral triangles. Furthermore, if the original triangle is inscribed in a unit circle (equivalently, its circumradius is $R=1$), then the stronger universal bound $$ \frac{K_A}{K_a}<\frac{\pi}{8} $$ holds. The constant $\pi/8$ and π^2 are best possible. Can this be proved?

Does the interval $(n^2, 4n^2)$ always contain a Mersenne prime exponent?

I have been analyzing the exponents p of known Mersenne primes $(2^p - 1)$ and noticed a pattern. I am conjecturing the following: For every $n \ge 1$, there exists a Mersenne prime exponent p such that: $n^2 < p < 4n^2$ This holds true for all 52 currently known Mersenne primes. The tightest squeeze occurs between $p = 127$ and $p = 521$: For $n = 11$, the interval is $(121, 484)$, catching $p = 127$. For $n = 12$, the interval is $(144, 576)$, catching $p = 521$. My Question: A formal proof is impossible right now since we don't even know whether or not there are infinitely many Mersenne primes. But from a probabilistic standpoint, does the Lenstra-Pomerance-Wagstaff heuristic suggest this pattern should hold globally, or is a massive gap statistically guaranteed to ruin it for a very large n?

Bijection related to formula for number of k length compositions of positive integer n and subsets of a set

From the book Enumerative Combinatorics 2nd ed. by R.P.Stanley, top of page 25 How does he come up with that $\binom{n-1}{k-1}$ answer and what does it have to do with bijection and maybe a precise answer as to what does bijection and it's inverse really mean ? I understand for example $(1+x)^n=\sum_{k=0}^n\binom {n}{k}x^k$ and for example that the number of solutions in k non negative integers to $n_1+n_2+...+n_k=n$ is $\binom{n+k-1}{k-1}$ so the number of solutions in strictly positive integers to $n_1+n_2+...+n_k=n+k$ is the same $\binom{n+k-1}{k-1}$ so then I could just put the

number of solutions to $n_1+n_2+...+n_k=n$ would just be to replace the n+k-1 in the first arg. of $\binom{n+k-1}{k-1}$ by just $n-1$ and would get his answer of $\binom{n-1}{k-1}$ but something tells me that is not a valid maneuver so not a valid way of proving it but just a coincidence ? And besides even if it is valid have not done it by method of bijection related to number of subsets of a set which is what he proclaims to be the way of envisioning such a conclusion since he states on the prior page 24 "There is a close connection between subsets of a set and compositions of a nonnegative integer." So does anyone have a clear way of describing all this and related subset of a set bijection ?

State of Baranovsky conjecture

Vladimir Baranovsky in his paper "The Variety of Pairs of Commuting Nilpotent Matrices is Irreducible", published in Transformation Groups, Vol 6, No.1, pages 3-8, 2001, posts a conjecture that all irreducible components of $\mathcal{N}_2(\mathfrak{g})$ (variety of nilpotent pairs of elements of complex semisimple Lie algebra $\mathfrak{g}$) have maximal dimension $\dim(\mathfrak{g})$, see end of Section 2 of the paper. He proves it for $\mathfrak{sl}_n$, i.e. for simple Lie algebras of type A. Now I wonder - Baranovsky paper is 25 years old and in meantime commuting nilpotent varieties got serious manpower. So, what is the state of his conjecture now?

A conjectural closed form for $\sum\limits_{n=0}^\infty\frac{n!\,(2n)!}{(3n+2)!}$

Let $$S=\sum\limits_{n=0}^\infty\frac{n!\,(2n)!}{(3n+2)!},\tag1$$ its numeric value is approximately $S \approx 0.517977853388534047...$${}^{[more\ digits]}$ S can be represented in terms of the generalized hypergeometric function: $$S={}_3F_2\left(\frac12,1,1;\ \frac43,\frac53;\ \frac4{27}\right)\cdot\frac12.\tag2$$ Let σ be the closed-form expression constructed from integers and elementary functions as follows: $$\sigma=3\,\alpha\,\ln(2\,\alpha+1)-\sqrt{\beta\,}\arccos\gamma,\tag3$$ where $$\alpha=\frac{\sqrt[3]{3\,}}{6\,\sqrt[3]{2\,}}\left(\sqrt[3]{9-\sqrt{69}}+\sqrt[3]{9+\sqrt{69}}\right),\tag4$$ $$\beta=\frac1{4\,\sqrt[3]{2\,}}\left(\sqrt[3]{25+3\,\sqrt{69}}+\sqrt[3]{25-3\,\sqrt{69}}\right)-\frac12,\tag5$$ $$\gamma=\frac1{6\,\sqrt[3]{2\,}}\left(\sqrt[3]{57\,\sqrt{69}-459}-\sqrt[3]{57\,\sqrt{69}+459}\right)+\frac12\tag6$$ are the unique real roots of the following cubic equations: $$8\,\alpha^3-2\,\alpha-1=0,\tag7$$ $$64\,\beta^3+96\,\beta^2+36\,\beta-23=0,\tag8$$ $$8\,\gamma^3-12\,\gamma^2+16\,\gamma+11=0.\tag9$$ Equivalently, $$\sigma = \frac{3\,p}{2}\,\ln\big(p+1\big)-\frac{1}{2}\sqrt{\frac{3-p}{p}}\arccos\Big(\frac{p-6}{6p+2}\Big)\tag{10}$$ where p is the plastic constant or the real root of $$p^3-p-1=0\tag{11}$$ It can be numerically checked that the following inequality holds: $$\Big|S-\sigma\Big|<10^{-10^5},\tag{12}$$ I conjecture that the actual difference is the exact zero, and thus S has an elementary closed form: $$\sum\limits_{n=0}^\infty\frac{n!\,(2n)!}{(3n+2)!}\stackrel?=3\,\alpha\,\ln(2\,\alpha+1)-\sqrt{\beta\,}\arccos\gamma,\tag{13}$$ I am asking for you help in proving this conjecture.

A conjecture $\int_{-\infty}^\infty\frac{\arctan e^x}{\cosh x}\cdot\frac{\tanh\frac{x}2}{x}dx\stackrel?=\frac\pi2\ln2$

I need to find a closed form for this integral: $$\mathcal{I}=\int_{-\infty}^\infty\frac{\arctan e^x}{\cosh x}\cdot\frac{\tanh\frac{x}2}{x}dx.$$ A numerical integration results in an approximation $\mathcal{I}\approx1.0887930451518...$, and WolframAlpha suggests a possible closed form for this number: $$\mathcal{I}\stackrel?=\frac\pi2\ln2$$ Is it the correct value of this integral? If so, how to prove it?

What are the recent advancements in mathematics that an undergraduate can understand?

I am an undergraduate student of mathematics. I am interested to know the conjectures that are proved in the last, say 5 or 10 years. Or any other development. Preferably in pure mathematics. One of the motives to ask this question is to get a feel for the cutting edge research areas. (If you feel this is too broad, please suggest me in comments to improve this question.) EDIT: I am interested to understand (not just know the statement of) the theorems. In your answers, you could just state the theorems, with references where I can research. If proofs are also provided, that would of course be acknowledged with deeper gratitude.

Totient summatory function

Let $\Phi(n) = \sum_{k=1}^n \phi(k)$ be the totient summatory function. Here is an interesting conjecture I've made: The ratio $\Phi(n^2)/\Phi(n)$ is an integer only for $n=1,2,3,5$ and 6. I made a program that shows that these are only solution for about $n<3000$. Is there some way to prove or disaprove it? Eventually, what about the general case: what conditions should satisfy numbers n and m so that ratio of their totient summatory functions is integer? Is there some paper that deals with it?

What's wrong with my conjecture?

I was doing math homework, and I formulated the following conjecture from one of the questions: If $f(x)$, $g(x)$ and $h(x)$ are continuous functions and the equations $f(x) = h(x)$ and $g(x) = h(x)$ both have only one root, then the equation $f(x) = g(x)$ has only one root. So can anyone find a counterexample? I can't think of one, but maybe that's because I haven't read Counterexamples in Analysis yet.

V3-019483 | MSE-538564

Conjecture $\int_0^1\frac{dx}{\sqrt[3]x\,\sqrt[6]{1-x}\,\sqrt{1-x\left(\sqrt{6}\sqrt{12+7\sqrt3}-3\sqrt3-6\right)^2}}=\frac\pi9(3+\sqrt2\sqrt[4]{27})$

Let $$\alpha=\sqrt{6}\ \sqrt{12+7\,\sqrt3}-3\,\sqrt3-6\,=\,\big(2+\sqrt{3}\big) \big(\sqrt{2}\ \sqrt[4]{27}-3\big)\,=\,\frac{3\sqrt{3}}{3+\sqrt2\ \sqrt[4]{27}}.\tag1$$ Note that α is the unique positive root of the polynomial equation $$\alpha^4+24\,\alpha^3+18\,\alpha^2-27=0.\tag2$$ Now consider the following integral: $$I=\int_0^1\frac{dx}{\sqrt[3]x\ \sqrt[6]{1-x}\ \sqrt{1-x\,\alpha^2}}.\tag3$$ I have a conjectured elementary value for it $$I\stackrel?=\frac\pi9\Big(3+\sqrt2\ \sqrt[4]{27}\Big)=\color{blue}{\frac{\pi}{\sqrt{3}\,\alpha}}.\tag4$$ Actually, the integral

I can be evaluated in an exact form using Mathematica or manually, using formula DLMF 15.6.1: $$I=\frac{4\,\sqrt\pi}{\sqrt3}\cdot\frac{\Gamma\left(\frac56\right)}{\Gamma\left(\frac13\right)}\cdot{_2F_1}\left(\frac12,\frac23;\ \frac32;\ \alpha^2\right),\tag5$$ but I could not find a way to simplify this result to (4). So, my conjecture can be restated in a different form: $${_2F_1}\left(\frac12,\frac23;\ \frac32;\ \alpha^2\right)\stackrel?=\frac{\sqrt2+\sqrt[4]3}{4\,\sqrt[4]{27}}\cdot\frac{\Gamma\left(\frac13\right)}{\Gamma\left(\frac56\right)}\cdot\sqrt\pi\tag6$$ or $$\sum_{n=0}^\infty\frac{\Gamma\left(n+\frac23\right)}{(2\,n+1)\,\Gamma(n+1)}\alpha^{2\,n}\stackrel?=\frac{3+\sqrt2\,\sqrt[4]{27}}{18}\cdot\frac{\pi^{3/2}}{\Gamma\left(\frac56\right)}.\tag7$$ The conjecture can also be given in terms of the incomplete beta function: $$B\left(\alpha^2;\ \frac12,\frac13\right)\stackrel?=\frac{\sqrt\pi}2\cdot\frac{\Gamma\left(\frac13\right)}{\Gamma\left(\frac56\right)}.\tag8$$ Question: Is the conjecture indeed true? Note: It holds numerically up to at least 10^4 decimal digits. Conjecture 2 Let $$ {\small \begin{multline} \beta=\frac{21}4+\frac{9\,\sqrt5}4-\frac{15}8\sqrt{750-330\,\sqrt5}-\frac{33}8\sqrt{150-66\,\sqrt5} \\ + \frac12\sqrt{3\left(165+75\,\sqrt5-46\,\sqrt{750-330\,\sqrt5}-103\,\sqrt{150-66\,\sqrt5}\right)}. \end{multline}}\tag9$$ Added later: We can simplify it to $$ \small\beta=\frac 3 4 \left(7+3 \sqrt 5-\sqrt[4] 5 \sqrt{66+30 \sqrt 5}\right)+\frac 1 2 \sqrt{495+225 \sqrt 5-3 \sqrt{6 \big(8545+3821 \sqrt 5\big)}}.\tag{$9'$} $$ I conjecture that: $$\int_0^1\frac{dx}{\sqrt[3]x\ \sqrt[6]{1-x}\ \sqrt{1-x\,\beta^2}}\stackrel?=\color{blue}{\frac{2\,\pi}{5\,\sqrt3\,\beta}}.\tag{10}$$ I can imagine that if these conjectures are true, then there are generalizations for some other algebraic numbers.

Conjecture: $\int_0^1\frac{3x^3-2x}{(1+x)\sqrt{1-x}}K\big(\!\frac{2x}{1+x}\!\big)\,dx\stackrel?=\frac\pi{5\sqrt2}$

$$\int_0^1\frac{3x^3-2x}{(1+x)\sqrt{1-x}}K\left(\frac{2x}{1+x}\right)\,dx\stackrel?=\frac\pi{5\sqrt2}$$ The integral above comes from the evaluation of the integral $A=\int_0^{\pi/2}\frac{f(\theta)}\pi\,d\theta$, where $$f(\theta)=\int_0^\pi\frac{(3\sin^2\theta-2)\sin\theta\,d\phi}{\sqrt{2+2\sin\theta\cos\phi}}=\frac{\sqrt2(3\sin^2\theta-2)}{\csc\theta\sqrt{1+\sin\theta}}\int_0^{\pi/2}\left(1-\frac{2\sin\theta}{1+\sin\theta}\sin^2\gamma\right)^{-1/2}d\gamma,$$ where $\gamma=\phi/2$, and the right side integral is

$K\big(\!\frac{2\sin\theta}{1+\sin\theta}\!\big)$ by definition. After substitutions $x=\sin\theta$ and $y=\frac{2x}{1+x}$ we get $$\begin{align}A&=\frac{\sqrt2}\pi\int_0^1\frac{3x^3-2x}{(1+x)\sqrt{1-x}}K\left(\frac{2x}{1+x}\right)\,dx\\ &=\frac1\pi\int_0^1\frac{y^3+8y^2-8y}{(2-y)^3\sqrt{y^2-3y+2}}K(y)\,dy\stackrel ?=\frac15,\end{align}$$ where the integral has been numerically evaluated to suggest the analytic result on the right to several thousand digits. Is there any way to prove this equality, and are there any generalizations of this conjecture to include other parameters? P.S. Not that it's overly relevant to the question, but for the interested reader, the original integral comes from the following physics problem: [Morin Intro to Classical Mechanics, Ex. 10.12] The earth bulges slightly at the equator, due to the centrifugal force in the earth's rotating frame. The goal of this exercise is to find the shape of the earth, first incorrectly, and then correctly. (a) The common incorrect method is to assume that the gravitation force from the slightly nonspherical earth points toward the center, and to then calculate the equipotential surface (incorporating both the gravitational and centrifugal forces). Show that this method leads to a surface whose height (relative to a spherical earth of the same volume) is given by $h(\theta)=R\big(\!\frac{R\omega^2}{6g}\!\big)(3\sin^2\theta-2)$, where θ is the polar angle (the angle down from the north pole), and R is the radius of the earth. (b) The above method is incorrect, because the slight distortion of the earth causes the gravitational force to not point toward the center of the earth (except at the equator and the poles). This tilt in the force direction then changes the slope of the equipotential surface, and it turns out (although this is by no means obvious) that this effect is of the same order as the slope of the surface found in part (a). Your task: Assuming that the density of the earth is constant, and that the correct height takes the form of some constant factor f times the result found in part (a), show that $f=5/2$. Do this by demanding that the potential at a pole equals the potential at the equator.

Lines formed from vertices of n-gons equate to triangular numbers.

Noticed something neat tonight! The number of unique lines you can form by connecting the vertices of an n-gon is equal to the (n-1)th triangular number. (e.g. in a square all 4 veritices make 4 lines (4 sides to a square), and then I can also connect any verticie to another verticie that is not directly to the left or right, assuming that it hasn't already been connected to that one earlier. So on a square the top right can connect to the bottom left (later on the bottom left can't connect to the top right because it already has), and the top left and connect to the bottom right. 6 unique lines (the 3rd triangular number is 6!) This works for any n-gon too!) I'm wondering if this property has already been known, I couldn't find anything about it online. Also, if so, does it have a name? I can't think of any real application for it other than, if this is held to be true than those who believe a digon is a circle/ellipsoid/ovaloid would be wrong (and it is currently widely held that a digon is a circle/ellipsoid/ovaloid), because then the 1st triangle-number would be "2", but if a digon was rather just a straight line with 2 end points, then the first triangular number would be "1" (which it is!) A digon would be two lines (NOT CURVES) that overlap and form a closed polygon with area 0 and perimeter 2*s.

An integral $\int_0^\infty P_s(x-1)\,e^{-x}\,dx$ involving Legendre functions

Let $P_s(x)$ denote the Legendre functions of the 1^{st} kind, i.e. the Legendre polynomial generalized to an arbitrary (not necessarily integer) order s. It can be expressed using the hypergeometric function: $$P_s(x)={_2F_1}\left(-s,s+1;\ 1;\ \frac{1-x}2\right).\tag1$$ Let's consider the definite integral $$\mathcal{J}(s)=\int_0^\infty P_s(x-1)\,e^{-x}\,dx.\tag2$$ It evaluates to integer values when $s\in\mathbb{Z}^+$. Using a computer-assisted search for the general term formula, I discovered the following conjecture, that I haven't yet been able to prove: $$\mathcal{J}(s)\stackrel?=\left(K_{3/2}(1)\cdot I_{s+1/2}(-1)-I_{3/2}(-1)\cdot K_{s+1/2}(1)\right)\sqrt{-1},\tag3$$ where $I_\nu(z)$ and $K_\nu(z)$ are the modified Bessel functions of the 1^{st} and 2^{nd} kind. Unfortunately, it only seems to hold for $s\in\mathbb{Z}^+$, and does not generalize to non-integer values of s. Can we prove the conjecture (3)? Can we find a more general formula that holds not only for integer values of s? Can we find (or at least conjecture) a closed form for $\mathcal{J}(1/2)$?

Conjectured closed form for $\int_0^1x^{2\,q-1}\,K(x)^2dx$ where $K(x)$ is the complete elliptic integral of the 1st kind

I am interested in a general closed-form formula for integrals of the following form: $$\mathcal{J}_q=\int_0^1x^{2\,q-1}\,K(x)^2dx,\tag0$$ where $K(x)$ is the complete elliptic integral of the 1st kind: $$K(x)={_2F_1}\left(\frac12,\frac12;\ 1;\ x^2\right)\frac\pi2\\=\int_0^{\pi/2}\frac{d\phi}{\sqrt{1-x^2\sin^2\phi}}=\int_0^1\frac{dz}{\sqrt{1-x^2z^2\vphantom{|^2}}\sqrt{1-z^2\vphantom{|^2}}}.\tag1$$ I could not find a suitable integral in DLMF or Gradshteyn-Ryzhik or Prudnikov tables of integrals. Mathematica was not able to evaluate it either, even when the parameter q was fixed to an integer (Note: In Mathematica you would write EllipticK[x^2] for $K(x)$ because of a different convention for the modulus parameter). But, numerical integration and lookups in WolframAlpha and ISC+ suggest that there are closed forms for (at least some) postitive integer values of the parameter q. For example, $$\mathcal{J}_1\stackrel?=\frac{7\,\zeta(3)}4,\ \mathcal{J}_2\

stackrel?=\frac{7\,\zeta(3)}8+\frac14,\\\mathcal{J}_3\stackrel?=\frac{77\,\zeta(3)}{128}+\frac{17}{64},\
\mathcal{J}_4\stackrel?=\frac{119\,\zeta(3)}{256}+\frac{881}{3456},\tag2$$ where $\zeta(3)$ is the Apéry constant. It looks that the general formula for postitive integer values of q is $$\mathcal{J}_q\stackrel?=a_q\,\zeta(3)+b_q,\tag3$$ where $a_q,\,b_q$ are some rational coefficients. I tried to find general formulae for these coefficients, and actually discovered plausible candidates for both. Conjecturally, a_q can be expressed in terms of a generalized hypergeometric function: $$a_q\stackrel?=\frac{7\,\pi}4\cdot\frac{{_4F_3}\left(\begin{array}{c}\frac12,\,\frac12,\,1-q,\,1-q\\1,\,\frac32-q,\,\frac32-q\end{array}\middle|\ 1\right)}{\Gamma\left(\frac32-q\right)^2\ \Gamma(q)^2}.\tag4$$ Somewhat suprisingly, this scarish expression seems to evaluate only to rationals for all $q\in\mathbb{Z}^+$. For b_q I found only a conjectural recurrence relation: $$b_1\stackrel?=0,\ b_2\stackrel?=\frac14,\ b_q\stackrel?=\frac{2\,(2\,q-3)\,\left(2\,q^2-6\,q+5\right)\cdot b_{q-1}-4\,(q-2)^3\cdot b_{q-2}+1}{4\,(q-1)^3},\tag5$$ but I could not find a general term formula for it. Can we prove that the closed forms shown in (2) are correct? Can we prove that the formula (3) holds for all $q\in\mathbb{Z}^+$ with some rational coefficients $a_q,\,b_q$? Are my conjectured formulae for these coefficients $(4),\,(5)$ correct? Can the formula (4) be expanded in terms of simpler functions? Is there a general term formula for (5)? Can we find (or at least conjecture) a general closed-form formula for $\mathcal{J}_q$ where q is not necessarily an integer?

open conjectures in real analysis targeting real valued functions of a single real variable

I am hoping that this question (if in acceptable form) be community wiki. Are there any open conjectures in real analysis primarily targeting real valued functions of a single real variable ? (it may involve other concepts but primarily targeting these type of functions and no involvement of number theory). Its not that i am going to attack them right away (not due to lack of interest but time) but am just curious to know them. Also how difficult it is get a new result in this area ?

Conjecture $_2F_1\left(\frac14,\frac34;\,\frac23;\,\frac13\right)=\frac1{\sqrt{\sqrt{\frac4{\sqrt{2-\sqrt[3]4}}+\sqrt[3]{4}+4}-\sqrt{2-\sqrt[3]4}-2}}$

Using a numerical search on my computer I discovered the following inequality: $$\left|\,{_2F_1}\left(\frac14,\frac34;\,\frac23;\,\frac13\right)-\rho\,\right|<10^{-20000},\tag1$$ where ρ is the positive root of the polynomial equation
$$12\,\rho^8-12\,\rho^4-8\,\rho^2-1=0,\tag2$$ that can be expressed in radicals: $$\rho=\frac1{\sqrt{\sqrt{\frac4{\sqrt{2-\sqrt[3]{4\vphantom{\large1}}}}}+\sqrt[3]{4}+4}-\sqrt{2-\sqrt[3]4}-2}}.\tag3$$ Based on this inequality I conjecture that the actual difference is the exact zero, i.e.

$$\color{#808080}{_2F_1\left(\frac14,\frac34;\,\frac23;\,\frac13\right)=\rho}.\tag4$$ I looked up in DLMF and MathWorld, but did not find a known special value with exactly these parameters. It also appears that CAS like Maple or Mathematica do not know this identity. Could you please suggest any ideas how to prove the conjecture (4)? Update: I can propose even more general conjecture: $$\color{#808080}{27\,(x-1)^2\cdot{_2F_1}\left(\tfrac14,\tfrac34;\tfrac23;x\right)^8+18\,(x-1)\cdot{_2F_1}\left(\tfrac14,\tfrac34;\tfrac23;x\right)^4-8\cdot{_2F_1}\left(\tfrac14,\tfrac34;\tfrac23;x\right)^2=1}$$

Why is $2^a > a^3$?

I found this rather interesting and maybe, a bit too obvious for some people property about 2 raised to some power. $2^a > a^3$, if $a=0,a=1 \text{ or } a\ge 10$.($a \in N$) I seem to get a bit of intuition as to why this happens(although the intuition is in "micro units of intuition"). Somebody please provide me some intuition regarding it the mathematical/logic way.

If AC is false , is this statement about the halting problem true?

Assume AC is false. (AC = axiom of choice) Let n,m be positive integers. Let $f: \Bbb N \rightarrow \Bbb N$ and $f(m)=m$. Let $g(n,m)=1$ if the iterations $f(n),f(f(n)),...$ converges to m. If $g(n,m)=1$, let $G(n,g)=x$ be the (min) amount of iterations needed to arrive at m. Statement : If one can prove that $g(n,m)=1$ for all n then one can prove an upper boundary $T(n)$ for $G(n,g)$. For example if one could prove Collatz : $g(n,1)=1$ is true for all n <=> Collatz is true. $\implies G(n,g) < T(n)$ and $T(n)$ equals (for example) $2^{2^{2^n}}$ This statement comes from someone I know, and I was not able to find a counterexample. Im not sure if this statement is a named conjecture or theorem yet. And I do not know if its true of course. I do know however that ZFC is required to prove Goodstein's theorem and there is no upper bound known for $G(n,g)$ here. So I think if AC is true then the statement is false. I considered this statement to be an axiom too , but that would mean it cannot be proved or disproved which I doubt. But who knows.

Proof envolving center of a group and conjugacy classes

I need to prove that every group G of order 9 is abelian. So, this is what I've done so far: There are three options for $[G:Z(G)]$: $[G:Z(G)]=1$, in this case we are done, since $G=Z(G)$ and that means G is abelian. $[G:Z(G)]=3$, in this case, we have that $G/Z(G)$ is cyclic, and that implies that G is abelian (I proved it earlier). $[G:Z(G)]=9$, since this means that $Z(G)=\left\{e\right\}$, we have that: $|G|=|Z(G)|+\sum_{x\notin Z(G)}|[x]|$ (while $[x]$ means the conjugacy class represented by x) and then $\sum_{x\notin Z(G)}|[x]|=8$, but I couldn't find the contradiction here. Any help would be appreciated.

Are $ut + 1$ and $ut + t + 1$ both prime for some t for any u?

Conjecture : For any natural number u, there is a natural number t such that $ut + 1$ and $ut + t + 1$ are both prime. So we get a solution of the equation $$au - b(u+1) = -1$$ with prime numbers a and b by setting $a := ut + t + 1 , b := ut + 1$: $$(ut+t+1)u - (ut+1)(u+1) = u^2t+ut+u-u^2t-ut-u-1 = -1$$ Motivation : If the conjecture is true, then for any natural number n, there is a pair $(a,a+1)$ of consecutive squarefree numbers with exactly n distinct prime factors. I checked the conjecture with PARI and for $u\le10^6$, it is true. The largest number t necessary to produce the prime pair is 3420 for the number

829123 upto $u = 10^6$

All about a failed conjecture.

Some months ago I made the following conjecture - Let $d(n)$ denote the number of divisors of $n $. Then let N be a number such that $d(N)$ divides N . Also let $I= \frac{N}{d(N)}$ which is defined as the "Index of Beauty of N ". Then, For every number I there exists a number N such that I is the index of beauty of N. This conjecture was proved false by Greg Martin here. He said that it can be showed by exaustive computation that the following I fail the conjecture under 1000 are $\{18, 27, 30, 45, 63, 64, 72, 99, 105, 112, 117, 144, 153, 160, 162, 165, 171, 195, 207, 225, 243, 252, 255, 261, 279, 285, 288, 294, 320, 333, 336, 345, 352, 360, 369, 387, 396, 405, 416, 423, 435, 441, 465, 468, 477, 490, 504, 531, 544, 549, 555, 567, 576, 603, 608, 612, 615, 616, 625, 639, 645, 657, 684, 705, 711, 726, 728, 735, 736, 747, 792, 795, 801, 810, 828, 840, 873, 880, 885, 891, 909, 915, 927, 928, 936, 952, 960, 963, 981, 992\}$ Now what I am interested is that sequence of I that fails. (i) Is this sequence infinite?How? (ii)Is there any approximation which can tell the number of such failed I less than a fixed x (iii)If the sequence is infinite then are there canonical forms in which all of the values are in our list.

Symmetry of bicycle-lock numbers

Suppose you have a combination bicycle lock of this sort: with n dials and k numbers on each dial. Let $m(n,k)$ denote the minimum number of turns that always suffice to open the lock from any starting position, where a turn consists of rotating any number of adjacent rings by one place. For example $m(2,10)=6$ and $m(3,10)=10$. I have found an efficient algorithm to compute these numbers, which reveals a symmetry I can’t currently explain: $m(n, k+1) = m(k, n+1)$ This is such a striking symmetry that I guess it has a simple explanation. Can anyone find one? Here’s the table of values for small n and k, exhibiting the conjectured symmetry: n\k| 2 3 4 5 6 7 8 9 10 ---+---------- 1 | 1 1 2 2 3 3 4 4 5 2 | 1 2 2 3 4 4 5 6 6 3 | 2 2 4 4 6 6 8 8 10 4 | 2 3 4 6 6 8 9 10 12 5 | 3 4 6 6 9 9 12 12 15 6 | 3 4 6 8 9 12 12 15 16 7 | 4 5 8 9 12 12 16 16 20 8 | 4 6 8 10 12 15 16 20 20 9 | 5 6 10 12 15 16 20 20 25 10 | 5 7 10 12 15 18 20 24 25

Closed form for $\int_{-1}^1\frac{\ln\left(2+x\,\sqrt3\right)}{\sqrt{1-x^2}\,\left(2+x\,\sqrt3\right)^n}dx$

I'm trying to find a closed form for the following integral: $$\mathcal{J}(n)=\int_{-1}^1\frac{\ln\left(2+x\,\sqrt3\right)}{\sqrt{1-x^2}\,\left(2+x\,\sqrt3\right)^n}dx\tag1$$ I have conjectured values of $\mathcal{J}(n)$ (supported by numerical inegration) for some integer values of n: $$\begin{align}&\mathcal{J}(1)\stackrel?=-\pi\ln\left(\frac32\right),\\&\mathcal{J}(2)\stackrel?=-\pi\left(1+2\ln\left(\frac32\right)\right),\\&\mathcal{J}(3)\stackrel?=-\pi\left(\frac{15}4+\frac{11}2\ln\left(\frac32\right)\right),\\&\mathcal{J}(4)\stackrel?=-\pi\left(\frac{77}6+17\ln\left(\frac32\right)\right).\end{align}\tag2$$ These values suggest that a general form for $n\in\mathbb{N}$ is $$\mathcal{J}(n)\stackrel?=-\pi\left(a_n+b_n\ln\left(\frac32\right)\right),\tag3$$ where a_n, b_n are some rational coefficients. Moreover, I conjecture that $$b_n\stackrel?={}_2F_1\left(1-n,n;\,1;\,-\frac12\right).\tag4$$ Are my conjectures true? Can we find a formula or recurrence relation for a_n? Can we find a general formula for $\mathcal{J}(z)$ for non-integer values of z?

Conjecture: When does $n=ab$, with $a\leq b\leq 2a$?

I conjecture that if this occurs, a and b are unique. Obviously if n is an odd prime, this does not occur, and if $n=a^2$, it does. In any case, what is the set of numbers such that this sort of factorization exists? For example, $510=17\cdot30$, and $17\leq 30\leq 34$. An equivalent formulation is that the set $S_n=\{(x,\frac nx)\mid\sqrt{\frac n2}\leq x\leq\sqrt{2n}\}$ has at most one integral point (ie., $|S_n\cap \mathbb Z\times\mathbb{Z}|\in\{0,1\}~\forall n$).

Conjectured closed form of $G^{2~2}_{3~3}\left(1\middle|\begin{array}c1,1;b+1\\b,b;0\end{array}\right)$

In my answer to this question, I come across the following case of the Meijer G-function: $$F(b)=G^{2~2}_{3~3}\left(1\middle|\begin{array}c1,1;b+1\\b,b;0\end{array}\right), b>0$$ and based on my experiments, $F(b)$ have the following closed form: $$F(b) \stackrel?=\frac{\Gamma(b)}{b}\left(-\gamma-\psi(b)+\frac{2^{1-b}}{b}{_2F_1}\left(\begin{array}c1,1\\b+1\end{array}\middle|-1\right)+b{_3F_2}\left(\begin{array}c1,1,b+1\\2,2\end{array}\middle|-1\right)\right)$$ Is there any chance of proving this? Edit: Using the definition of the Meijer G-Function, $F(b)$ have the integral representation: $$F(b)=\frac{1}{2\pi}\int^{+\infty}_{-\infty}\frac{\Gamma(\tfrac{b}{2}+ix)\Gamma(\tfrac{b}{2}-ix)}{\tfrac{b^2}{4}+x^2}dx.$$ Edit 2: I've found a further generalization: $$F(b,z)=G^{2~2}_{3~3}\left(z\middle|\begin{array}c1,1;b+1\\b,b;0\end{array}\right)=\frac{1}{2\pi}\int^{+\infty}_{-\infty}\frac{\Gamma(\tfrac{b}{2}+ix)\Gamma(\tfrac{b}{2}-ix)}{\tfrac{b^2}{4}+x^2}e^{(b/2+ix)\log z}dx\\ \stackrel?=\frac{\Gamma(b)z^b}{b}\left(-\log z-\gamma-\psi(b)+\frac{(z+1)^{1-b}}{b}{_2F_1}\left(\begin{array}c1,1\\b+1\end{array}\middle|-z\right)+bz~{_3F_2}\left(\begin{array}c1,1,b+1\\2,2\end{array}\middle|-z\right)\right), b\not\in\{0,-1,-2,\dots\},z\neq0,-1.$$ Edit 3: Further simplified the ${_2F_1}$ part.

Prove that $\lim\limits_{x\to\infty} \frac{\Gamma(x+1,x(1+\epsilon))}{x\Gamma(x)}=0$.

I conjecture that for any $\epsilon>0$, we have $$ \lim_{x\to\infty} \frac{\Gamma(x+1,x(1+\epsilon))}{x\Gamma(x)}=0 $$ where $\Gamma(x,a) = \int_a^\infty t^{x-1}e^{-t} \mathrm{d}t$ denotes the incomplete Gamma function, and $\Gamma(x) = \Gamma(x,0)$ is the Gamma function. I'm also happy with the weaker conjecture $$ \lim_{x\to\infty} \frac{\int_{x(1+\epsilon)}^\infty t^{x-1}\log(1+t)e^{-t} \mathrm{d}t}{x\Gamma(x)}=0 $$ but I doubt that it is any easier. Any clues? NB: the stronger conjecture is obtained from the weaker conjecture by upper-bounding $\log(1+t)$ by t

I have a conjecture on local max/min , can any of you propose a contradiction?

If f is a non-piecewise function defined continuous on an interval I, and within that interval I, there exists a value x, such that $f`(x)$ (derivative of f) does not exist , then at that value x, is a local $\max/\min$ value.

Measure Theory Conjecture

While I was doing some math here, I made this conjecture. Let $f_n:X\rightarrow \mathbb{R}$ be a sequence of measurable functions from the measure space $(X,\mathcal{A},\mu)$ to the measurable space $(\mathbb{R},\mathcal{B}(\mathbb{R}))$, and let $\mu:\mathcal{A}\rightarrow[0,\infty]$ be a positive measure. Consider that for all $\varepsilon > 0$, the sets $A_n = \{x\in X: \ |f_n(x)| > \varepsilon\}$ are such that $$\limsup_{n\to\infty}\mu(A_n) = 0.$$ Then its true that $f_n\to0$, μ-almost everywhere. The thing is, I think it is true but I don't know how to prove it. You can consider μ as a probability measure if it makes more easier to prove. Thank you.

Infinitely many primes of the $\sum_{i=0}^{a} n^{i}+m\cdot\sum_{i=0}^{b} n^{i}$ form?

How to show that there is infinitely many prime numbers of the form: $p=\sum_{i=0}^{a} n^{i}+m\cdot\sum_{i=0}^{b} n^{i}$ where: $m\in \mathbb{Z}^{*}$, $a,b,n\in \mathbb{N}$, $\gcd(a+1,b+1)=1$ For example: $\sum_{i=0}^{6} 10^{335\cdot i}+8648\cdot \sum_{i=0}^{4} 10^{335\cdot i}$ is prime number.

If $\gcd(a,b)=1$, and a is even and b is odd then $\gcd(2^{a}+1,2^{b}+1)=1$?

How to prove that: $\gcd(a,b)=1 \Rightarrow \gcd(2^{a}+1,2^{b}+1)=1$,where a is even and b is odd natural number For example: $\gcd(2^8+1,2^{13}+1)=1 , \gcd(2^{64}+1,2^{73}+1)=1$ I know that Knuth showed that: $\gcd(2^{a}-1,2^{b}-1)=2^{\gcd(a,b)}-1$ so: $\gcd(a,b)=1\Rightarrow \gcd(2^{a}-1,2^{b}-1)=1$ but I don't see whether this fact is useful.

Prove that there exists an m such that for any $n>m$ there exists at least one prime between c_n and n

Let c_n be the n-th composite. Then the problem is to prove that- $\pi(c_n)-\pi(n)>0$ $\forall n>m$ I have tried to progress in the problem using an elementary approach. So far I have been able to prove the following trivial results- For any $n>7$ the composite c_n satisfies the inequality $2n>c_n>n$. $\pi(c_n)=c_n-n-1$ $\pi(x)\geq \pi(p)$ $\iff$ $x \geq p$. Where p is a prime. Notice that when the R.H.S always implies L.H.S. To prove the converse we note that $\pi(x) > \pi(p)$ $\implies$ $x>p$. The problem occurs when $\pi(x) = \pi(p)$. In that case if $x<p$ then it would imply that $\pi(x) < \pi(p)$, contradicting our hypothesis. Hence proved. The $\pi(c_n)$-th prime is strictly less then c_n for any $n>7$. $c_n$$_-$$_\pi$$_($$_n$$_)$$_-$$_1$ $=$ $n-1$ $\iff$ n is a prime and $c_n$$_-$$_\pi$$_($$_n$$_)$$_-$$_1$ $=$ n $\iff$ n is a composite. Using 5 it can be proved that c_n $\geq$ $n+\pi(n)+1$. But what I want is strict inequality. I have proved that the function $\Psi(n)=c_n-n-\pi(n)-1$ is increasing between two consecutive primes. Notice that the statement of the problem is equivalent to the following statement- Prove that the $\pi(c_n)$-th prime is strictly greater then n for any $n > m$. Actually I have borrowed the problem from the AoPS site. For the actual post see http://www.artofproblemsolving.com/Forum/viewtopic.php?f=52&t=588724.

Tangent at average of two roots of cubic with one real and two complex roots

I was able to easily prove that the tangent at the average of two roots of a real cubic polynomial passed through the third root of the function. But I have only done this for functions with three distinct real roots using $y = (x-a) (x-b) (x-c)$ as the function. I calculated the derivative of the function in terms of (x= midpoint of a and b) and then just subbed in ($x = c$) in the equation of the tangent that I worked out to prove this conjecture. BUT!! Now, I am trying to prove the same for cubics with one real and two complex roots. I am using $y = (x -d) (x-(a+bi) (x- (a-bi))$ where d is the one real root. So far, I have found the derivative of this to be \begin{align} dy/dx &= 2(x-d)(x-a) + (x-a-bi)(x-a+bi)\\ &= 2(x-d)(x-a) + x^2 + a^2 - bi^2\\ &= 2(x-a) (x-d) (x^2 + a^2 + b^2) \end{align} The average of the two roots I have used is $((a+bi/2) + (a - bi/2))/2 = a$ I have already proved it for this average of roots! But!! I also tried the other possible average of roots $((d + a +bi)/2)$ where the Point of contact I used is $((a+bi+d)/2), -((a+bi-d)/2)^3$ Why is that the equation of the tangent I worked out for this second possible pair of roots using ($m =ystep/xstep$) is not equalling zero when I sub in the third root into the equation of tangent I am getting?? Maybe I have calculated some things wrong? Can you please help me prove the conjecture? Plus, another mini question: Can cubic polynomials be non-real? because when we say all cubic polynomials must have at least one real root, it implies that the cubic is real. So can I say that a cubic with an imaginary coefficient is non-real? I won't try to prove this conjecture for non-real cubics though. Can you please help me?! I would really appreciate even a bit of help Sorry and Thanks!! =)

Equal perimeters of squares and right angled isosceles triangles

Consider a square ABCD having length l and breadth. Now start folding the sides AB and AC so that the figure becomes something like this $$$ All the vertical and horizontal folds/stairs are equal in length. The perimeter of the figure is equal to the the perimeter of the square. As we increase the number of divisions, the length of each fold/stair decreases. Let the number of stairs/folds be n. As $n\rightarrow\infty$ the figure becomes a right angled isosceles triangle BCD. The perimeter of triangle BCD should be equal to the perimeter of square ABCD since as we increase the number of folds/stairs the perimeter remains the same. Can anyone please correct me where I have gone wrong?

Find all n so that c_n $>$ $\pi(n^2)$

Find all n $\in$ $\mathbb{N}$ so that p_{c_n} $>$ n^2 where p_n denotes the n-th prime and c_n, the n-th composite. I have tried doing the problem using The stronger version of Roger's Theorem, i.e., by the inequality, $$\ln n + \ln \ln n > \dfrac {p_n}{n} > \ln n + \ln \ln n - 1$$ but in vain. I think that the problem is true for all sufficiently large values of n. Even a proof of only this claim will also be appreciated.

Low Level Books on Conjectures/Famous Problems

I am currently an undergraduate math/CS major with coursework done in Linear Algebra, Vector Calculus (that covered a significant amount of Real 1 material), Discrete Math, and about to take courses in Algebra and Real Analysis 1. I was wondering if there are any books about famous problems (Riemann, Goldbach, Collatz, etc) and progress thus far that are accessible to me. If possible, I would prefer them to have more emphasis on the math rather than the history. As an example, I enjoyed reading Fermat's Enigma by Simon Singh but was disappointed in how it glossed over most of the math. If there are any suggestions I would greatly appreciate it.

Intuitively, what separates Mersenne primes from Fermat primes?

A Mersenne prime is a prime of the form 2^n-1. A Fermat prime is a prime of the form 2^n+1. Despite the two being superficially very similar, it is conjectured that there are infinitely many Mersenne primes but only finitely many Fermat primes. Is there an intuition that can help me appreciate the nature of that seemingly paradoxical difference?

A conjecture of parallelogram inside convex and central symmetric curve

Assume Q is a convex central symmetric curve, whose area is $\displaystyle S$. The area of the maximum parallelogram inside Q is $\displaystyle S'$. How to prove the conjecture that $\displaystyle \frac{S'}{S} \ge \frac{2}{\pi}=0.6366\dots$? For example, If Q is an ellipse, $\displaystyle S'=2ab$, $\displaystyle S=\pi ab$. If Q is a regular hexagon, $\displaystyle \frac{S'}{S}= \frac{2}{3}$. It's trivial that $\displaystyle \frac{S'}{S} \ge \frac{1}{2}$, and I know how to prove $\displaystyle \frac{S'}{S} \ge \frac{4}{4+\pi}=0.56\dots$ From many reason, I believe this conjecture is true. Denote MAP="Maximum Area Parallelogram": For any Q and any direction θ, let $P(Q,\theta)$ be the area of MAP which have a corner in this direction. $S'=\max\{P(Q,\theta)\}$. In order to make $\frac{S'}{S}$ smallest, We need keep the largest one of $\{P(Q,\theta)\}$ small while S is a constant. Ellipse just keeps everyone in $\{P(Q,\theta)\}$ average. This is very special, I don't think there will be other curve having this property. On the other hand, distribute equally always lead to the min-max in our knowledge. About the $\frac{4}{4+\pi}$ lowerbound, the idea is as follows: First, use polar function $r(\theta)$ to describe the curve. The condition is that $r(a)r(b)\sin|a-b|\leq C$, and we want to bound is $S=\int_{\theta}{r(\theta)}^2$. Second, Without lose of generality, We assume $r(0)=r(90)=1,C=1$, and assume Q is in the boundary of $Z=\{(x,y)|-1\leq x,y\leq 1\}$. Third, let $a=r(\theta)$ and $b=r(\theta+90)$ and find a bound for (a^2+b^2) by Cauchy-Inequality. and it will give a bound for the area S.

Interesting Property of Numbers in English

I was playing with the letters in numbers written in English and I found something quite funny. I found that if you count the number of letters in the number and write this as a number and then count the number of letters in this new number and keep repeating the process, you will arrive at the number 4. I've confirmed this (using a computer program) for all numbers up to 999999 and was wondering if there's a way to prove this or to find a counter example for which it does not hold. Just to give an example of the above statement, let's start with thirty seven (I chose this randomly) Thirty seven has 11 letters in it, Eleven has 6 letters in it, Six has three letters in it, Three has 5 letters in it, Five has 4 letters in it. It may look like I just picked this number, so let me show this for another random number, say 999. Nine hundred and ninety nine has 24 letters in it, Twenty four has 10 letters in it, Ten has 3 letters in it, Three has 5 letters in it, Five has 4 letters in it. What are your thoughts on how to prove this? (Just a note: I only confirmed this for numbers written in the standard British way of writing numbers - for example 101 is one hundred and one)

A Conjecture on The Generalization of Quadratic Reciprocity Law

Is there any way to prove the following conjecture regarding the Generalization of Quadratic Reciprocity Law. The statement being, $$ \left(\dfrac{a_1}{a_2}\right)\left(\dfrac{a_2}{a_3}\right) \ldots\left(\dfrac{a_n}{a_1}\right)=(-1)^{\left(\frac{a_1-1}{2}\right) \left(\frac{a_2-1}{2}\right) \ldots \left(\frac{a_n-1}{2}\right)}$$ where the symbols are Jacobi Symbols and $\operatorname{gcd}(a_i,a_j)=1$ for $i\neq j$ and $a_i>1$ forall i satisfying $1 \leq i \leq n$. One of my friend told me that the argument for $n=3$ and when all a_i are distinct primes, is a modification of the Eisenstein's argument for proving the Quadratic Reciprocity Law itself. Instead of considering a planer rectangle as in Eisenstein's Proof of Quadratic Reciprocity Law if we consider a cuboid and count the number of points (x,y,z) (where x,y and z are all integers) that is within this cuboid and not on any outer surface, then the proof would be done. And when the result is proved for primes it can be proved in general also. However the problem is that in this scheme we can't visualize an n-dimensional rectangle and thus can't forward his argument to n dimensions, though we think that it can be generalized. Is there any way to help visualizing it or is there any way to prove the result in a simpler way?

At most n functions satisfy $f(x)=\bigl(x-f(a_1)\bigr)\bigl(x-f(a_2)\bigr)\dots\bigl(x-f(a_n)\bigr)$?

Some background: I was trying to solve the functional equation $f\bigl(f(x)\bigr)=\sin x$. I realized that $f(\pi n)$ is a root of f for all integers n, because $f\bigl(f(\pi n)\bigr)=\sin(\pi n)=0$. Thus, we can write f as $f(x)=A\bigl(x-f(0)\bigr)\bigl(x-f(\pi)\bigr)\bigl(x-f(-\pi)\bigr)\dots$. The problem now is to find all functions f that solve this. I couldn't even begin on this, so I decided to try letting the constant A equal 1, and to try some simpler versions first. E.g. For $f(x)=x-f(0)$ we find the unique solution $f(x)=x$; for $f(x)=\bigl(x-f(0)\bigr)\Bigl(x-f\left(\sqrt{2}\right)\Bigr)$ we find two solutions, namely $f(x)\in \left\{x^2-1,x^2-2\left(\sqrt{2}-1\right)x\right\}$. I solved many more examples, and then conjectured that: Let $a_i\in \mathbb{C}$ for $i=1,2,\dots,n$. Prove that the functional equation $f(x)=\bigl(x-f(a_1)\bigr)\bigl(x-f(a_2)\bigr)\dots\bigl(x-f(a_n)\bigr)$ has exactly n distinct solutions. Finally, I realized that if this is proved, then it would "follow" (I don't know if this is rigorous but I hope someone knows how to make it rigorous) that our original functional equation $f(x)=\bigl(x-f(0)\bigr)\bigl(x-f(\pi)\bigr)\bigl(x-f(-\pi)\bigr)\dots$ (I put $A=1$) has infinitely many solutions. Thanks for reading.

Can decimals/fractions be odd or even?

At school I asked the question and I kept wondering "Can fractions or decimals be odd or even?"

A variation of Fermat's little theorem in the form $a^{n-d}\equiv a$ (mod p).

Fermat's little theorem states that for n prime, $$ a^n \equiv a \pmod{n}. $$ The values of n for which this holds are the primes and the Carmichael numbers. If we modify the congruence slightly, $$ a^{n - 1} \equiv a \pmod{n}, $$ the values of n for which it holds are listed in A216090: 1, 2, 6, 10, 14, 22, 26, 30, 34, 38, 46, ... More generally, we can examine the values of n where $$ a^{n - d} \equiv a \pmod{n} $$ for all a and a given d. $d = 0$ gives the primes/Carmichael numbers, $d = 1$ gives the sequence A216090, and $d = 2$ gives the sequence 1, 2, 3, 15, 21, 33, 39, 51, 57, 69, 87, ... For $d = 3$, the sequence grows much more rapidly: 1, 2, 4, 6, 154, 4774, 23254, 179014, 187054, 1066054, 1168654, ... But for $d = 4$, the growth slows down again: 1, 2, 3, 5, 65, 85, 145, 165, 185, 205, 265, ... The first few d values which give fast-growing sequences for n are 3, 7, 8, 11, 15, 17, 19, 23, 24, and 26. In general, the sequence seems to grow particularly quickly when $d + 1$ is not squarefree. I've proven this generalization of Korselt's criterion that characterises the possible n values for a given d: Theorem (Generalized Korselt's criterion). Let d be an arbitrary integer, and n a positive integer such that and $n \ge d + 1$. Then $a^{n - d} \equiv a \pmod{n}$ for all $a \in \mathbb{Z}$ if and only if either $n = 1$ or 2; $n = d + 1$; or n is squarefree, and for each of n's prime divisors p_i, $(p_i - 1) \vert (n - d - 1)$. Additionally, I've observed the following pattern that would explain why the squarefreeness of $d + 1$ matters: Conjecture. When $d + 1$ is squarefree, many prime multiples of $d + 1$ are valid values for n. But if $d + 1$ is not squarefree, no multiples of it (except possibly itself) are feasible values for n. In either case, valid n values which are not multiples of $d + 1$ are much less abundant. Any ideas how to tackle this conjecture, or at least make it more explicit?

A conjecture concerning primes and algebra

A monoid morphism $\psi:\mathbb Z_+\!\!\rightarrow\mathbb Z_+$ is defined by an arbitrary function $f:\mathbb Z_+\!\!\rightarrow\mathbb Z_+$ and defines a group homomorphism $\varphi:\mathbb Q_+\!\!\rightarrow\mathbb Q_+$: $\psi(a\cdot b)=\psi(a)\cdot\psi(b)\Rightarrow\psi(\prod p_i^{n_i})=\prod\psi(p_i)^{n_i}$, so any function $i\mapsto \psi(p_i)$ defines ψ. Further, since $\varphi(\frac{1}{n})=\frac{1}{\varphi(n)}$ a function f uniquely defines the group

homomorphism φ. For fun I intend to study the group homomorphism generated by the identity function $i\mapsto\omega(p_i)=i$. Then $\omega:\mathbb Z_+\!\!\rightarrow\mathbb Z_+$ seems to be an algebraic analogue to the analytic approach with $\pi(N)$ since also ω is a left inverse to the prime number function p_n. In the diagram ω is the blue curve and π the red and one can see (especially if the picture is loaded and viewed in a larger scale) that $\omega(1)>\pi(1),\; \omega(35)>\pi(35)$ and $\omega(49)>\pi(49)$. Of course ω and π coincide for all primes, but also for other values as $91,\;95$ and 133. However, I have tested all values less than 2^{16} and $\omega(N)\leq\pi(N)$ for $N>49$ in this interval. I have no idea how to prove the conjecture (if possible) but I will try to construct a program that (in principle) can test any interval of integers. Edit: I realize now that it is virtually impossible to make such a program, but with help of arrays of primes my program have tested all values $< 1\,000\,000$ and the only numbers for which $\omega(N)\geq\pi(N)$ (italic numbers stands for '$>$') are: $\mathit{1},\,9,\,15,\,21,\,25,\,\mathit{35},\,39,\,\mathit{49},\,57,\,65,\,91,\,95,\,133$. Conjecture: For $N=\prod p_k^{n_k}>49$ it holds that $\prod k^{n_k}\leq\pi(N)$. Thoughtful: from an analytic point of view ω seems to be very irregular, but algebraically it is an almost canonical morphism.

V3-019748 | OC-3020

Universal Structure of Graph Product Kernels | main.tex:1136-1137

定位：main.tex:1136-1137。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Ian J. Leary; Nansen Petrosyan | 2026-05-08

仅定位元数据，没有正文 | 原始来源 | metadata only; original license: arxiv_nonexclusive_distrib

V3-019749 | OC-3098

Positive density for Sun's 2^k+m conjecture | main.tex:90-93

定位：main.tex:90-93。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Songlin Han; Jinbo Yu | 2026-05-15

仅定位元数据，没有正文 | 原始来源 | metadata only; original license: arxiv_nonexclusive_distrib

V3-019750 | OC-323

On certain subspaces of 2-configuration spaces of graphs | paper1Final.tex:2730-2732

定位：paper1Final.tex:2730-2732。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Byung Hee An; Sangrok Oh | 2026-02-17

仅定位元数据，没有正文 | 原始来源 | metadata only; original license: arxiv_nonexclusive_distrib

V3-019751 | OC-3384

Rigidity in the Positive Mass Theorem with C^0 Decay | main.tex:166-168

定位：main.tex:166-168。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Liam Mazurowski; Xuan Yao | 2026-05-28

仅定位元数据，没有正文 | 原始来源 | metadata only; original license: arxiv_nonexclusive_distrib

V3-019752 | OC-34

Beyond singular value gaps in randomized subspace approximation | WangTownsendSIMAX.tex:1052-1058

定位：WangTownsendSIMAX.tex:1052-1058。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Christopher Wang; Alex Townsend | 2026-03-01

仅定位元数据，没有正文 | 原始来源 | metadata only; original license: arxiv_nonexclusive_distrib

V3-019753 | OC-3414

Dual Chow polynomials of matroids and posets | main.tex:2354-2356

定位：main.tex:2354-2356。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Giovanni Caiolo; Luis Ferroni; Elena Hoster | 2026-05-27

仅定位元数据，没有正文 | 原始来源 | metadata only; original license: arxiv_nonexclusive_distrib

V3-019754 | OC-3431

Homological Nielsen realization for the manifolds $\#_n \mathbb{CP}^2$ | final_draft.tex:879-881

定位：final_draft.tex:879-881。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Ethan Pesikoff | 2026-05-26

仅定位元数据，没有正文 | 原始来源 | metadata only; original license: arxiv_nonexclusive_distrib

V3-019755 | OC-3435

Explicit class of finite-dimensional polynomial algebras with Wronskians over $\mathbb{R}^d$ as N-ary Lie brackets: beyond $\mathfrak{sl}(2)$ | FinDim220526.tex:2077-2079

定位：FinDim220526.tex:2077-2079。发布数据中的猜想候选；本卷仅提供论文与源码位置。

仅来源定位 | source_machine_label_real_open_conjecture | Markuss G. Ķēniņš; Arthemy V. Kiselev | 2026-05-26

C04 图论论文定位 | 372 条

V3-019937 | GAX-AX_3_coloring_diameter_2_quasipolynomial

Faster 3-colouring algorithm for graphs of diameter 3 | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Carla Groenland; Hidde Koerts; Sophie Spirkl | 2026-01-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019938 | GAX-AX_4_colorability_fixed_surface_complexity

Three-coloring triangle-free graphs on surfaces IV. Bounding face sizes of 4-critical graphs | 4-colorability on Fixed Surfaces (Open Step in Thomassen's Program)

论文中定位：4-colorability on Fixed Surfaces (Open Step in Thomassen's Program)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Daniel Kral; Robin Thomas | 2020-08-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019939 | GAX-AX_4_colorability_fixed_surface_polynomial_time

Three-coloring triangle-free graphs on surfaces I. Extending a coloring to a disk with one triangle | Open Problem: polynomial-time 4-colorability on fixed surfaces

论文中定位：Open Problem: polynomial-time 4-colorability on fixed surfaces；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Dan Kral; Robin Thomas | 2016-03-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019940 | GAX-AX_5_coloring_p4_rp3_free_complexity

Complexity dichotomy for List-5-Coloring with a forbidden induced subgraph | Open Problem: 5-Coloring complexity for H-free graphs with a P4 component

论文中定位：Open Problem: 5-Coloring complexity for H-free graphs with a P4 component；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Sepehr Hajebi; Yanjia Li; Sophie Spirkl | 2022-08-30

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019941 | GAX-AX_active_clustering_clique_algorithm_optimal

Active clustering for labeling training data | Conjecture 5

论文中定位：Conjecture 5；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Quentin Lutz; Élie de Panafieu; Alex Scott; Maya Stein | 2021-10-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019942 | GAX-AX_additive_chi_approx_kk_minor_free

Additive non-approximability of chromatic number in proper minor-closed classes | Open question: better additive approximation for K_{4k_0+1}-minor-free graphs

论文中定位：Open question: better additive approximation for K_{4k_0+1}-minor-free graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Ken-ichi Kawarabayashi | 2017-07-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019943 | GAX-AX_additive_chi_approx_minor_closed_triangle_free

Additive non-approximability of chromatic number in proper minor-closed classes | Open question: additive approximation for triangle-free graphs

论文中定位：Open question: additive approximation for triangle-free graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Ken-ichi Kawarabayashi | 2017-07-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019944 | GAX-AX_annulus_digraph_winding_one_crossing_free

When all directed cycles have length three | Conjecture 1.2

论文中定位：Conjecture 1.2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Paul Seymour | 2025-02-09

V3-019958 | GAX-AX_c4_free_counting_petersen_dodecahedron

Which graphs can be counted in C_4-free graphs? | Open Problem 2.17

论文中定位：Open Problem 2.17；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Benny Sudakov; Yufei Zhao | 2021-06-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019959 | GAX-AX_c5_free_triangle_removal_exponent

The regularity method for graphs with few 4-cycles | Optimality of the $o(n^{3/2})$ bound in Corollary 1.4

论文中定位：Optimality of the $o(n^{3/2})$ bound in Corollary 1.4；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Benny Sudakov; Yufei Zhao | 2021-09-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019960 | GAX-AX_c_closed_graphs_maximal_cliques_exponent

Finding Cliques in Social Networks: A New Distribution-Free Model | Open Problem (exact exponent for maximal cliques in c-closed graphs)

论文中定位：Open Problem (exact exponent for maximal cliques in c-closed graphs)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Tim Roughgarden; C. Seshadhri; Fan Wei; Nicole Wein | 2018-04-20

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019961 | GAX-AX_capture_time_higher_genus_bounds

Topological directions in Cops and Robbers | Capture time bounds for higher genus graphs

论文中定位：Capture time bounds for higher genus graphs；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Anthony Bonato; Bojan Mohar | 2018-04-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019962 | GAX-AX_capture_time_planar_linear_tightness

Topological directions in Cops and Robbers | Tightness of linear capture time bound for planar graphs

论文中定位：Tightness of linear capture time bound for planar graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Anthony Bonato; Bojan Mohar | 2018-04-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019963 | GAX-AX_chi_bounded_not_polynomially_chi_bounded

Graphs of bounded cliquewidth are polynomially $χ$-bounded | Open problem: χ-bounded vs. polynomially χ-bounded

论文中定位：Open problem: χ-bounded vs. polynomially χ-bounded；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Michał Pilipczuk | 2020-07-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019964 | GAX-AX_chromatic_threshold_digraph_cycle_orientations

Orientations of cycles in digraphs of high chromatic number and high minimum out-degree | Question 1.2

论文中定位：Question 1.2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Hidde Koerts; Benjamin Moore; Sophie Spirkl | 2025-03-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019965 | GAX-AX_chromatic_threshold_digraph_fixed_subdigraph

Orientations of cycles in digraphs of high chromatic number and high minimum out-degree | Question 4.1

论文中定位：Question 4.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Hidde Koerts; Benjamin Moore; Sophie Spirkl | 2025-03-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019966 | GAX-AX_chromatic_threshold_digraph_minimum_epsilon

Orientations of cycles in digraphs of high chromatic number and high minimum out-degree | Question 4.2

论文中定位：Question 4.2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Hidde Koerts; Benjamin Moore; Sophie Spirkl | 2025-03-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019967 | GAX-AX_chromatic_threshold_odd_cycles_undirected

Orientations of cycles in digraphs of high chromatic number and high minimum out-degree | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Hidde Koerts; Benjamin Moore; Sophie Spirkl | 2025-03-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019968 | GAX-AX_circular_drawing_digraph_forbidden_characterization

When all directed cycles have the same weight | Open Question on Circular Drawing Characterisation

论文中定位：Open Question on Circular Drawing Characterisation；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Eli Berger; Daniel Carter; Paul Seymour | 2026-01-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019969 | GAX-AX_clean_classes_finite_family_characterization

Induced subgraphs and tree-decompositions VII. Basic obstructions in H-free graphs | Question: finite families yielding clean H-free classes

论文中定位：Question: finite families yielding clean H-free classes；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tara Abrishami; Bogdan Alecu; Maria Chudnovsky; Sepehr Hajebi; Sophie Spirkl | 2023-11-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019970 | GAX-AX_clique_chromatic_dense_gnp_tight_constant

Clique coloring of dense random graphs | Informal Conjecture on Tight Constant for Clique Chromatic Number

论文中定位：Informal Conjecture on Tight Constant for Clique Chromatic Number；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Michael Krivelevich | 2017-11-05

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019971 | GAX-AX_clique_width_h1_h2_free_boundedness

Graph Isomorphism for (H_1,H_2)-free Graphs: An Almost Complete Dichotomy | Open Cases: Clique-Width Classification for (H_1,H_2)-Free Graphs

论文中定位：Open Cases: Clique-Width Classification for (H_1,H_2)-Free Graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Nicolas Bousquet; Konrad K. Dabrowski; Matthew Johnson; Daniël Paulusma; Théo Pierron | 2019-09-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019972 | GAX-AX_cluster_vertex_deletion_2_approximation

Improved approximation algorithms for hitting 3-vertex paths | 2-Approximation Conjecture for Cluster-VD

论文中定位：2-Approximation Conjecture for Cluster-VD；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Samuel Fiorini; Gwenaël Joret; Oliver Schaudt | 2019-02-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019973 | GAX-AX_coarse_menger_bounded_genus

Asymptotic structure. V. The coarse Menger conjecture in bounded path-width | Informal conjecture: coarse Menger for bounded genus

论文中定位：Informal conjecture: coarse Menger for bounded genus；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tung Nguyen; Alex Scott; Paul Seymour | 2025-09-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019974 | GAX-AX_coarse_menger_bounded_genus_surfaces

Asymptotic structure. VI. Distant paths across a disc | Conjecture 1.2 (Coarse Menger conjecture for surfaces)

论文中定位：Conjecture 1.2 (Coarse Menger conjecture for surfaces)；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tung Nguyen; Alex Scott; Paul Seymour | 2025-09-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019975 | GAX-AX_coarse_menger_distance_2_paths

Asymptotic structure. IV. A counterexample to the weak coarse Menger conjecture | Open case: Coarse Menger Conjecture for c=2

论文中定位：Open case: Coarse Menger Conjecture for c=2；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tung Nguyen; Alex Scott; Paul Seymour | 2025-08-20

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019976 | GAX-AX_coarse_treewidth_additive_quasi_isometry

Asymptotic structure. I. Coarse tree-width | Open question on Theorem 1.2 with $L=1$

论文中定位：Open question on Theorem 1.2 with $L=1$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tung Nguyen; Alex Scott; Paul Seymour | 2025-09-05

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019977 | GAX-AX_coherent_ideal_forest_filleting

Pure pairs. II. Excluding all subdivisions of a graph | Conjecture 2.4

论文中定位：Conjecture 2.4；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2020-06-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019978 | GAX-AX_complete_topological_graph_linear_disjoint_edges

A structure theorem for pseudo-segments and its applications | Optimal disjoint-edges bound in complete simple topological graphs

论文中定位：Optimal disjoint-edges bound in complete simple topological graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Janos Pach; Andrew Suk | 2023-12-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019979 | GAX-AX_cone_crossing_number_2_page_redrawing

The crossing number of the cone of a graph | Problem 4

论文中定位：Problem 4；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Carlos A. Alfaro; Alan Arroyo; Marek Derunár; Bojan Mohar | 2016-08-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019980 | GAX-AX_cone_crossing_number_minimum_function

The crossing number of the cone of a graph | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Carlos A. Alfaro; Alan Arroyo; Marek Derunár; Bojan Mohar | 2016-08-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019981 | GAX-AX_cone_crossing_number_simple_graphs_asymptotics

The crossing number of the cone of a graph | Conjecture on $f_s(k)$ asymptotics

论文中定位：Conjecture on $f_s(k)$ asymptotics；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Carlos A. Alfaro; Alan Arroyo; Marek Derunár; Bojan Mohar | 2016-08-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019982 | GAX-AX_connectivity_code_torus_product_cycles

Connectivity Graph-Codes | Open Problem: m(C_t × C_s) for all t, s

论文中定位：Open Problem: m(C_t × C_s) for all t, s；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon | 2023-09-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019983 | GAX-AX_constricting_hole_lengths_bounded_gaps

Induced subgraphs of graphs with large chromatic number. IV. Consecutive holes | Conjecture 1.5

论文中定位：Conjecture 1.5；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2018-02-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019984 | GAX-AX_constricting_hole_lengths_density_zero

Induced subgraphs of graphs with large chromatic number. IV. Consecutive holes | Problem 1.6

论文中定位：Problem 1.6；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2018-02-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019985 | GAX-AX_controlled_triangle_free_chromatic_4_hole

Induced subgraphs of graphs with large chromatic number. IV. Consecutive holes | Informal Question (on 2.1 for $\ell = 4$)

论文中定位：Informal Question (on 2.1 for $\ell = 4$)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2018-02-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019986 | GAX-AX_convex_drawings_vs_pseudocircular_drawings

Topological Drawings meet Classical Theorems from Convex Geometry | Open problem: convex drawings vs. pseudocircular drawings

论文中定位：Open problem: convex drawings vs. pseudocircular drawings；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Helena Bergold; Stefan Felsner; Manfred Scheucher; Felix Schröder; Raphael Steiner | 2024-07-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019987 | GAX-AX_convex_unit_distance_realization_gk

Convexly independent subsets of Minkowski sums of convex polygons | Open Question on Convex Unit Distance Realization of Graphs G_k

论文中定位：Open Question on Convex Unit Distance Realization of Graphs G_k；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Mateusz Skomra; Stéphan Thomassé | 2021-06-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019988 | GAX-AX_cop_number_genus_sqrt_g_growth

Notes on Cops and Robber game on graphs | Conjecture 8

论文中定位：Conjecture 8；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bojan Mohar | 2017-10-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019989 | GAX-AX_cop_number_outerplanar_classification

Topological directions in Cops and Robbers | Classification of outerplanar graphs by cop number

论文中定位：Classification of outerplanar graphs by cop number；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Anthony Bonato; Bojan Mohar | 2018-04-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019990 | GAX-AX_cop_number_planar_classification

Topological directions in Cops and Robbers | Classification of planar graphs by cop number

论文中定位：Classification of planar graphs by cop number；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Anthony Bonato; Bojan Mohar | 2018-04-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019991 | GAX-AX_cop_number_riemannian_surfaces_area_supremum

Notes on Cops and Robber game on graphs | Question (Riemannian surfaces): supremum of cop number for geometrically bounded surfaces

论文中定位：Question (Riemannian surfaces): supremum of cop number for geometrically bounded surfaces；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bojan Mohar | 2017-10-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019992 | GAX-AX_cop_number_riemannian_surfaces_constant_curvature

Notes on Cops and Robber game on graphs | Question (Riemannian surfaces): constant curvature surfaces

论文中定位：Question (Riemannian surfaces): constant curvature surfaces；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bojan Mohar | 2017-10-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019993 | GAX-AX_cop_number_riemannian_surfaces_cop_convergence

Notes on Cops and Robber game on graphs | Question (Riemannian surfaces): cop converging to robber

论文中定位：Question (Riemannian surfaces): cop converging to robber；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bojan Mohar | 2017-10-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019994 | GAX-AX_cop_number_riemannian_surfaces_genus_bounded

Notes on Cops and Robber game on graphs | Question (Riemannian surfaces): cop number bounded by genus

论文中定位：Question (Riemannian surfaces): cop number bounded by genus；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bojan Mohar | 2017-10-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019995 | GAX-AX_cop_number_riemannian_surfaces_worst_genus

Notes on Cops and Robber game on graphs | Question (Riemannian surfaces): worst surfaces of fixed genus

论文中定位：Question (Riemannian surfaces): worst surfaces of fixed genus；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bojan Mohar | 2017-10-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019996 | GAX-AX_cop_number_sublinear_treedepth

Cops and robber in graphs with bounded vertex cover number | Problem 9

论文中定位：Problem 9；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Prosenjit Bose; Louis Esperet; Jędrzej Hodor; Gwenaël Joret; Piotr Micek; Clément Rambaud | 2026-02-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019997 | GAX-AX_corners_popular_difference_abelian_groups

Triforce and Corners | Informal conjecture on extending Mandache's Theorem 1.1 to all abelian groups

论文中定位：Informal conjecture on extending Mandache's Theorem 1.1 to all abelian groups；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Ashwin Sah; Mehtaab Sawhney; David Stoner; Yufei Zhao | 2019-07-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019998 | GAX-AX_correlation_polytope_extension_complexity_treewidth

Extension Complexity of the Correlation Polytope | Conjecture 2

论文中定位：Conjecture 2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Samuel Fiorini; Tony Huynh; Marco Macchia; Johanna Seif | 2018-10-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-019999 | GAX-AX_corruption_detection_expansion_threshold

Distributed Corruption Detection in Networks | Open Problem: Expansion vs. Corruption Detection

论文中定位：Open Problem: Expansion vs. Corruption Detection；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Elchanan Mossel; Robin Pemantle | 2020-03-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020000 | GAX-AX_counting_perfect_matchings_alpha_2_hard

Exact Matching in Graphs of Bounded Independence Number | Conjecture 3

论文中定位：Conjecture 3；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Nicolas El Maalouly; Raphael Steiner | 2022-07-13

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020001 | GAX-AX_cover_free_families_optimal_size

Lower bounds for graph reconstruction with maximal independent set queries | Problem 5.1 (cover-free families)

论文中定位：Problem 5.1 (cover-free families)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Lukas Michel; Alex Scott | 2024-04-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020002 | GAX-AX_crossing_critical_max_degree_optimal_bounds

Bounded maximum degree conjecture holds precisely for c-crossing-critical graphs with $c \leq 12$ | Optimal degree bounds D_c for small c

论文中定位：Optimal degree bounds D_c for small c；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Drago Bokal; Zdeněk Dvořák; Petr Hliněný; Jesús Leaños; Bojan Mohar; Tilo Wiedera | 2021-05-05

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020003 | GAX-AX_cube_complex_boundary_distance_rigidity

Boundary rigidity of 3D CAT(0) cube complexes | Question 1

论文中定位：Question 1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | John Haslegrave; Alex Scott; Youri Tamitegama; Jane Tan | 2023-09-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020004 | GAX-AX_cubic_2_homogeneous_coloring_4_colors

Open problems of the 33rd Workshop on Cycles and Colourings | Problem 5.1

论文中定位：Problem 5.1；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | János Barát; Zdeněk Dvořák; Penny Haxell; František Kardoš; Borut Lužar; Alfréd Onderko; Jozef Rajník; Roman Soták; Nikolay Ulyanov | 2025-11-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020005 | GAX-AX_cubic_2_homogeneous_coloring_finite_exceptions

Open problems of the 33rd Workshop on Cycles and Colourings | Problem 5.2

论文中定位：Problem 5.2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | János Barát; Zdeněk Dvořák; Penny Haxell; František Kardoš; Borut Lužar; Alfréd Onderko; Jozef Rajník; Roman Soták; Nikolay Ulyanov | 2025-11-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020006 | GAX-AX_cubic_many_3_edge_colorings_reflexive

Reflexive coloring complexes for 3-edge-colorings of cubic graphs | Informal Conjecture on reflexive graphs and coloring abundance

论文中定位：Informal Conjecture on reflexive graphs and coloring abundance；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Fiachra Knox; Bojan Mohar; Nathan Singer | 2020-04-14

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020007 | GAX-AX_cubic_truncation_strong_6_edge_coloring

Open problems of the 33rd Workshop on Cycles and Colourings | Problem 4.1

论文中定位：Problem 4.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | János Barát; Zdeněk Dvořák; Penny Haxell; František Kardoš; Borut Lužar; Alfréd Onderko; Jozef Rajník; Roman Soták; Nikolay Ulyanov | 2025-11-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020008 | GAX-AX_cycles_union_k4_copies_4_colorable

Open problems of the 33rd Workshop on Cycles and Colourings | Problem 3.1

论文中定位：Problem 3.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | János Barát; Zdeněk Dvořák; Penny Haxell; František Kardoš; Borut Lužar; Alfréd Onderko; Jozef Rajník; Roman Soták; Nikolay Ulyanov | 2025-11-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020009 | GAX-AX_cyclic_clique_minor_min_degree_bound

Lollipops, dense cycles and chords | Question 1.2

论文中定位：Question 1.2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Beatriz Martins; Stéphan Thomassé; Nicolas Trotignon | 2025-10-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020010 | GAX-AX_degenerate_graphs_flexibility_d_plus_1_lists

List coloring with requests | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Sergey Norin; Luke Postle | 2018-11-17

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020011 | GAX-AX_degenerate_graphs_polynomial_kempe_sequences

Kempe changes in degenerate graphs | Polynomial Kempe sequences for degenerate graphs

论文中定位：Polynomial Kempe sequences for degenerate graphs；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Vincent Delecroix; Clément Legrand-Duchesne | 2021-12-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020012 | GAX-AX_degenerate_kr_free_extremal_order_exponential

Coloring small locally sparse degenerate graphs and related problems | Problem 6.3

论文中定位：Problem 6.3；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Domagoj Bradač; Jacob Fox; Raphael Steiner; Benny Sudakov; Shengtong Zhang | 2026-01-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020013 | GAX-AX_degenerate_kr_free_fractional_chromatic_max

Coloring small locally sparse degenerate graphs and related problems | Problem 4.1

论文中定位：Problem 4.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Domagoj Bradač; Jacob Fox; Raphael Steiner; Benny Sudakov; Shengtong Zhang | 2026-01-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020014 | GAX-AX_degenerate_kr_free_fractional_chromatic_sublinear

Coloring small locally sparse degenerate graphs and related problems | Problem 6.4

论文中定位：Problem 6.4；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Domagoj Bradač; Jacob Fox; Raphael Steiner; Benny Sudakov; Shengtong Zhang | 2026-01-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020015 | GAX-AX_degenerate_triangle_free_subexponential_order_coloring

Coloring small locally sparse degenerate graphs and related problems | Problem 6.1

论文中定位：Problem 6.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Domagoj Bradač; Jacob Fox; Raphael Steiner; Benny Sudakov; Shengtong Zhang | 2026-01-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020016 | GAX-AX_degree_bounded_classes_c4_free_polynomial

Induced C_4-free subgraphs with large average degree | Polynomial bound in k for C4-free subgraphs

论文中定位：Polynomial bound in k for C4-free subgraphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Xiying Du; António Girão; Zach Hunter; Rose McCarty; Alex Scott | 2023-11-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020017 | GAX-AX_degree_bounded_classes_polynomial_bounding_function

Induced C_4-free subgraphs with large average degree | Polynomial degree-bounding function for hereditary degree-bounded classes

论文中定位：Polynomial degree-bounding function for hereditary degree-bounded classes；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Xiying Du; António Girão; Zach Hunter; Rose McCarty; Alex Scott | 2023-11-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020018 | GAX-AX_digraph_forward_connected_pairs_approximation_ratio

Temporalizing digraphs via linear-size balanced bi-trees | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stéphane Bessy; Stéphan Thomassé; Laurent Viennot | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020019 | GAX-AX_digraph_forward_connected_pairs_request_approximation

Temporalizing digraphs via linear-size balanced bi-trees | Problem 4

论文中定位：Problem 4；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stéphane Bessy; Stéphan Thomassé; Laurent Viennot | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020020 | GAX-AX_digraph_left_maximal_dfs_tree_complexity

Temporalizing digraphs via linear-size balanced bi-trees | Problem 3

论文中定位：Problem 3；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stéphane Bessy; Stéphan Thomassé; Laurent Viennot | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020021 | GAX-AX_digraph_strong_balanced_bitree_linear_constant

Temporalizing digraphs via linear-size balanced bi-trees | Problem 2

论文中定位：Problem 2；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stéphane Bessy; Stéphan Thomassé; Laurent Viennot | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020022 | GAX-AX_digraph_strong_forward_cover_log_n

Temporalizing digraphs via linear-size balanced bi-trees | Conjecture 1

论文中定位：Conjecture 1；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stéphane Bessy; Stéphan Thomassé; Laurent Viennot | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020023 | GAX-AX_disjoint_paths_stability_two_np_complete

Disjoint paths in unions of tournaments | Informal Conjecture (vertex-disjoint paths, stability number two)

论文中定位：Informal Conjecture (vertex-disjoint paths, stability number two)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour | 2018-12-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020024 | GAX-AX_distributed_coloring_sparse_sublinear_rounds

Distributed coloring in sparse graphs with fewer colors | Open problem on sublinear round complexity

论文中定位：Open problem on sublinear round complexity；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Marthe Bonamy; Nicolas Bousquet; Louis Esperet | 2018-12-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020025 | GAX-AX_distributed_delta_list_coloring_randomized_rounds

Distributed coloring in sparse graphs with fewer colors | Question on randomized list-coloring round complexity

论文中定位：Question on randomized list-coloring round complexity；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Marthe Bonamy; Nicolas Bousquet; Louis Esperet | 2018-12-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020026 | GAX-AX_divisible_subdivision_clique_minor_f_growth

Divisible subdivisions | Open Problem (asymptotic behavior of f(H,q))

论文中定位：Open Problem (asymptotic behavior of f(H,q))；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Michael Krivelevich | 2021-06-29

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020027 | GAX-AX_divisible_subdivision_g_q_linear

Divisible subdivisions | Informal Conjecture (linearity of g(q))

论文中定位：Informal Conjecture (linearity of g(q))；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Michael Krivelevich | 2021-06-29

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020028 | GAX-AX_domination_2_independence_tied_classes

Characterization of sparse monotone graph classes with bounded domination-to-2-independence ratio | Problem 2

论文中定位：Problem 2；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Zdeněk Dvořák; Lukas Michel; David Mikšaník | 2026-01-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020029 | GAX-AX_domination_packing_ratio_bounded_2_independence

Characterization of sparse monotone graph classes with bounded domination-to-2-independence ratio | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Zdeněk Dvořák; Lukas Michel; David Mikšaník | 2026-01-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020030 | GAX-AX_domination_packing_ratio_bounded_characterization

On graph classes with constant domination-packing ratio | Question 9.1

论文中定位：Question 9.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Mónika Csikós; Anna Gujgiczer; Yelena Yuditsky | 2025-03-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020031 | GAX-AX_domination_packing_ratio_bounded_given_class

On graph classes with constant domination-packing ratio | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Mónika Csikós; Anna Gujgiczer; Yelena Yuditsky | 2025-03-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020032 | GAX-AX_ell_holed_graphs_structure_small_ell

Graphs with all holes the same length | Open Problem: characterisation of ℓ-holed graphs for $\ell \in \{4, 5, 6\}$

论文中定位：Open Problem: characterisation of ℓ-holed graphs for $\ell \in \{4, 5, 6\}$；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Linda Cook; Jake Horsfield; Myriam Preissmann; Cléophée Robin; Paul Seymour; Ni Luh Dewi Sintiari; Nicolas Trotignon; Kristina Vušković | 2023-12-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020033 | GAX-AX_epsilon_t_nets_size_computation

The $ε$-t-Net Problem | The ε-t-Net Problem

论文中定位：The ε-t-Net Problem；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Bruno Jartoux; Chaya Keller; Shakhar Smorodinsky; Yelena Yuditsky | 2020-03-16

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020034 | GAX-AX_erdos_ginzburg_ziv_constant_fixed_k

Erdős-Ginzburg-Ziv constants by avoiding three-term arithmetic progressions | Open Question on s((Z/kZ)^n) for fixed k

论文中定位：Open Question on s((Z/kZ)^n) for fixed k；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Lisa Sauermann | 2018-04-17

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020035 | GAX-AX_erdos_posa_planar_minor_constant_polynomial

A tight Erdős-Pósa function for planar minors | Open Problem (constant c vs. |H|)

论文中定位：Open Problem (constant c vs. |H|)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Wouter Cames van Batenburg; Tony Huynh; Gwenaël Joret; Jean-Florent Raymond | 2019-10-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020036 | GAX-AX_erdos_szekeres_collinear_variant_ell_dependence

Big line or big convex polygon | Open Problem (Introduction)

论文中定位：Open Problem (Introduction)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Xiaoyu He; Dhruv Mubayi; Andrew Suk; Jacques Verstraete | 2024-05-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020037 | GAX-AX_euclidean_ramsey_diameter_free_bound

Lines in Euclidean Ramsey theory | Open problem: removing diameter dependence from Theorem 1.1

论文中定位：Open problem: removing diameter dependence from Theorem 1.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox | 2018-03-20

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020038 | GAX-AX_euclidean_ramsey_l3_vs_lm

Lines in Euclidean Ramsey theory | Open problem: $E^n \not\to (\ell_3, \ell_m)$ for large m

论文中定位：Open problem: $E^n \not\to (\ell_3, \ell_m)$ for large m；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox | 2018-03-20

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020039 | GAX-AX_euclidean_ramsey_unit_distance_vs_copy

Lines in Euclidean Ramsey theory | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox | 2018-03-20

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020040 | GAX-AX_even_hole_free_bounded_degree_treewidth

On the tree-width of even-hole-free graphs | Conjecture 2

论文中定位：Conjecture 2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Isolde Adler; Eun Jung Kim; Ni Luh Dewi Sintiari; Nicolas Trotignon | 2020-08-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020041 | GAX-AX_even_hole_free_chordal_modulator

Induced subgraphs and tree decompositions VIII. Excluding a forest in (theta, prism)-free graphs | Informal Conjecture (chordal modulator characterization for even-hole-free graphs)

论文中定位：Informal Conjecture (chordal modulator characterization for even-hole-free graphs)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tara Abrishami; Bogdan Alecu; Maria Chudnovsky; Sepehr Hajebi; Sophie Spirkl | 2023-01-28

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020042 | GAX-AX_even_hole_free_coloring_polynomial

Tree Independence Number IV. Even-hole-free Graphs | Open Problem: Polynomial-time Coloring on even-hole-free graphs

论文中定位：Open Problem: Polynomial-time Coloring on even-hole-free graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Peter Gartland; Sepehr Hajebi; Daniel Lokshtanov; Sophie Spirkl | 2024-07-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020043 | GAX-AX_even_hole_free_independent_set_complexity

Maximum independent sets in (pyramid, even hole)-free graphs | Open problem: MIS complexity in even-hole-free graphs

论文中定位：Open problem: MIS complexity in even-hole-free graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Stéphan Thomassé; Nicolas Trotignon; Kristina Vušković | 2019-12-24

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020044 | GAX-AX_even_hole_free_independent_set_polynomial

Tree Independence Number IV. Even-hole-free Graphs | Open Problem: Polynomial-time MWIS on even-hole-free graphs

论文中定位：Open Problem: Polynomial-time MWIS on even-hole-free graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Peter Gartland; Sepehr Hajebi; Daniel Lokshtanov; Sophie Spirkl | 2024-07-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020045 | GAX-AX_even_hole_k4_diamond_free_treewidth

(Theta, triangle)-free and (even hole, K_4)-free graphs. Part 2 : bounds on treewidth | Open Question: (even hole, K4, diamond)-free treewidth/cliquewidth

论文中定位：Open Question: (even hole, K4, diamond)-free treewidth/cliquewidth；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marcin Pilipczuk; Ni Luh Dewi Sintiari; Stéphan Thomassé; Nicolas Trotignon | 2020-10-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020046 | GAX-AX_f3n_subspace_free_sets_exponential_base

Popular progression differences in vector spaces II | Informal Question (correct exponential constant in r(n,m))

论文中定位：Informal Question (correct exponential constant in r(n,m))；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Huy Tuan Pham | 2019-11-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020047 | GAX-AX_fat_minor_quasi_isometry_trees_planar

Asymptotic structure. III. Excluding a fat tree | Informal question: validity of Conjecture 1.2 for trees and planar graphs

论文中定位：Informal question: validity of Conjecture 1.2 for trees and planar graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tung Nguyen; Alex Scott; Paul Seymour | 2025-09-13

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020048 | GAX-AX_flip_distance_complexity_binary_trees_rotation

Shortest paths on polymatroids and hypergraphic polytopes | Complexity of Rotation Distance Between Binary Search Trees

论文中定位：Complexity of Rotation Distance Between Binary Search Trees；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jean Cardinal; Raphael Steiner | 2023-11-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020049 | GAX-AX_flip_distance_complexity_rectangulations

Shortest paths on polymatroids and hypergraphic polytopes | Complexity of Flip Distance Between Rectangulations

论文中定位：Complexity of Flip Distance Between Rectangulations；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jean Cardinal; Raphael Steiner | 2023-11-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020050 | GAX-AX_fo_minimization_approximation_bounded_expansion_ptas

Approximation metatheorems for classes with bounded expansion | Problem 6

论文中定位：Problem 6；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák | 2021-10-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020051 | GAX-AX_forest_of_lanterns_pervasive

Induced subgraphs of graphs with large chromatic number. V. Chandeliers and strings | Conjecture: every forest of lanterns is pervasive

论文中定位：Conjecture: every forest of lanterns is pervasive；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour | 2021-05-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020052 | GAX-AX_frozen_coloring_glauber_delta_o_n

Frozen $(Δ+1)$-colourings of bounded degree graphs | Informal: Δ = o(n) condition not necessary for Corollary 2

论文中定位：Informal: Δ = o(n) condition not necessary for Corollary 2；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Nicolas Bousquet; Guillem Perarnau | 2018-11-30

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020053 | GAX-AX_frozen_coloring_probability_exponent

Frozen $(Δ+1)$-colourings of bounded degree graphs | Informal: Exponent in Theorem 1 not optimal

论文中定位：Informal: Exponent in Theorem 1 not optimal；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Nicolas Bousquet; Guillem Perarnau | 2018-11-30

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020054 | GAX-AX_generalized_coloring_number_cc_characterization

On generalized choice and coloring numbers | Open Problem: Characterization of parameters satisfying (CC)

论文中定位：Open Problem: Characterization of parameters satisfying (CC)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Jakub Pekárek; Jean-Sébastien Sereni | 2019-02-26

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020055 | GAX-AX_gnm_subgraph_moderate_deviations_sparse

Moderate deviations of subgraph counts in the Erdős-Rényi random graphs $G(n,m)$ and $G(n,p)$ | Remark 1.2 (Open Problem on Sparse Densities)

论文中定位：Remark 1.2 (Open Problem on Sparse Densities)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Christina Goldschmidt; Simon Griffiths; Alex Scott | 2020-02-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020056 | GAX-AX_gnp_chromatic_concentration_lower_bound

On the concentration of the chromatic number of random graphs | Open problem on lower bound for concentration interval

论文中定位：Open problem on lower bound for concentration interval；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott | 2017-10-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020057 | GAX-AX_gnp_h_free_clique_count_threshold

Many cliques in H-free subgraphs of random graphs | Motivating Question (Introduction)

论文中定位：Motivating Question (Introduction)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Alexandr Kostochka; Clara Shikhelman | 2017-11-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020058 | GAX-AX_graph_codes_cube_length_interval_vectors

Graph-codes | Open problem: binary vectors with cube-length forbidden symmetric difference

论文中定位：Open problem: binary vectors with cube-length forbidden symmetric difference；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon | 2023-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020059 | GAX-AX_graph_codes_even_edges_density_vanishes

Graph-codes | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon | 2023-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020060 | GAX-AX_graph_codes_k4_density_vanishes

Graph-codes | Informal question: is $d_{K_4}(n) = o(1)$?

论文中定位：Informal question: is $d_{K_4}(n) = o(1)$?；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon | 2023-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020061 | GAX-AX_graph_codes_linear_even_h_bounds

Graph-codes | Open problem: tighter bounds for linear graph-codes

论文中定位：Open problem: tighter bounds for linear graph-codes；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon | 2023-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020062 | GAX-AX_graph_codes_odd_intersection_edge_coloring

Graph-codes | Open problem: minimum edge-coloring with odd intersection property

论文中定位：Open problem: minimum edge-coloring with odd intersection property；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon | 2023-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020063 | GAX-AX_graph_isomorphism_fpt_clique_width

Graph Isomorphism for (H_1,H_2)-free Graphs: An Almost Complete Dichotomy | Open Question: FPT Algorithm for Graph Isomorphism Parameterized by Clique-Width

论文中定位：Open Question: FPT Algorithm for Graph Isomorphism Parameterized by Clique-Width；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Nicolas Bousquet; Konrad K. Dabrowski; Matthew Johnson; Daniël Paulusma; Théo Pierron | 2019-09-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020064 | GAX-AX_graph_isomorphism_h1_h2_free_dichotomy

Graph Isomorphism for (H_1,H_2)-free Graphs: An Almost Complete Dichotomy | Research Question (Introduction)

论文中定位：Research Question (Introduction)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Nicolas Bousquet; Konrad K. Dabrowski; Matthew Johnson; Daniël Paulusma; Théo Pierron | 2019-09-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020065 | GAX-AX_graph_reconstruction_mis_queries_adaptive_deterministic

Lower bounds for graph reconstruction with maximal independent set queries | Problem 5.3 (adaptive vs non-adaptive gap)

论文中定位：Problem 5.3 (adaptive vs non-adaptive gap)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Lukas Michel; Alex Scott | 2024-04-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020066 | GAX-AX_graph_reconstruction_mis_queries_randomized_nonadaptive

Lower bounds for graph reconstruction with maximal independent set queries | Problem 5.2 (randomised non-adaptive optimality)

论文中定位：Problem 5.2 (randomised non-adaptive optimality)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Lukas Michel; Alex Scott | 2024-04-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020067 | GAX-AX_grid_ramsey_equals_hypergraph_clique_star

Hypergraph Ramsey numbers of cliques versus stars | Informal Conjecture: r(K^(3)_4, S^(3)_n) and gr(G_{2x2}, K_n) have the same order

论文中定位：Informal Conjecture: r(K^(3)_4, S^(3)_n) and gr(G_{2x2}, K_n) have the same order；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Xiaoyu He; Dhruv Mubayi; Andrew Suk; Jacques Verstraete | 2022-10-07

V3-020068 | GAX-AX_grid_ramsey_rectangle_vs_clique

Hypergraph Ramsey numbers of cliques versus stars | Grid Ramsey Problem (gr(G_{2x2}, K_n))

论文中定位：Grid Ramsey Problem (gr(G_{2x2}, K_n))；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Xiaoyu He; Dhruv Mubayi; Andrew Suk; Jacques Verstraete | 2022-10-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020069 | GAX-AX_grundy_coloring_biclique_free_fpt

Grundy Coloring & friends, Half-Graphs, Bicliques | FPT on $K_{t,t}$-free graphs for Grundy Coloring

论文中定位：FPT on $K_{t,t}$-free graphs for Grundy Coloring；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Édouard Bonnet; Eun Jung Kim; Florian Sikora | 2020-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020070 | GAX-AX_grundy_coloring_half_graph_free_fpt

Grundy Coloring & friends, Half-Graphs, Bicliques | FPT on $H_{t,t}$-free graphs for Grundy Coloring and b-Chromatic Core

论文中定位：FPT on $H_{t,t}$-free graphs for Grundy Coloring and b-Chromatic Core；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Édouard Bonnet; Eun Jung Kim; Florian Sikora | 2020-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020071 | GAX-AX_h_free_clique_maximizers_polynomial_error

H-free subgraphs of dense graphs maximizing the number of cliques and their blow-ups | Informal Conjecture (error term in Proposition 1.4)

论文中定位：Informal Conjecture (error term in Proposition 1.4)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Clara Shikhelman | 2017-06-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020072 | GAX-AX_h_free_coloring_dichotomy_all_k

List-k-Coloring H-free graphs for all $k>4$ | Full dichotomy for k-Coloring on H-free graphs ($k\geq 3$)

论文中定位：Full dichotomy for k-Coloring on H-free graphs ($k\geq 3$)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Sepehr Hajebi; Sophie Spirkl | 2023-11-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020073 | GAX-AX_hat_guessing_number_complete_bipartite

The hat guessing number of graphs | Open question: exact value of $HG(K_{n,n})$

论文中定位：Open question: exact value of $HG(K_{n,n})$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Omri Ben-Eliezer; Chong Shangguan; Itzhak Tamo | 2020-01-15

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020074 | GAX-AX_hat_guessing_number_degree_degeneracy_bounds

The hat guessing number of graphs | Problem 1.4

论文中定位：Problem 1.4；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Omri Ben-Eliezer; Chong Shangguan; Itzhak Tamo | 2020-01-15

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020075 | GAX-AX_hat_guessing_universal_vertex_addition

On the Hat Guessing Number of Graphs | Problem on Hat Guessing Number After Adding a Universal Vertex

论文中定位：Problem on Hat Guessing Number After Adding a Universal Vertex；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Jeremy Chizewer | 2021-07-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020076 | GAX-AX_hereditary_tau_d_bounded_implies_polynomial_esperet

Polynomial bounds for chromatic number. V. Excluding a tree of radius two and a complete multipartite graph | Question: Polynomial bound analogue of Esperet's conjecture for τ_d

论文中定位：Question: Polynomial bound analogue of Esperet's conjecture for τ_d；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2023-01-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020077 | GAX-AX_heroes_complete_multipartite_delta_1_2_2

Heroes in oriented complete multipartite graphs | Question 1.4

论文中定位：Question 1.4；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Guillaume Aubian; Pierre Charbit | 2023-12-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020078 | GAX-AX_heroes_delta_1_2_2_k1_p2_free

On heroes in digraphs with forbidden induced forests | Open problem: hero status of $\Delta(1,2,2)$

论文中定位：Open problem: hero status of $\Delta(1,2,2)$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alvaro Carbonero; Hidde Koerts; Benjamin Moore; Sophie Spirkl | 2023-06-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020079 | GAX-AX_heroes_k1_join_delta_1_1_h

Heroes in oriented complete multipartite graphs | Question 5.4

论文中定位：Question 5.4；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Guillaume Aubian; Pierre Charbit | 2023-12-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020080 | GAX-AX_heroes_oriented_star_delta_1_m_m

On heroes in digraphs with forbidden induced forests | Open problem: hero status of $\Delta(1,m,m')$ for degree-4 oriented stars

论文中定位：Open problem: hero status of $\Delta(1,m,m')$ for degree-4 oriented stars；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alvaro Carbonero; Hidde Koerts; Benjamin Moore; Sophie Spirkl | 2023-06-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020081 | GAX-AX_heroic_sets_bounded_dichromatic_finite_families

On heroes in digraphs with forbidden induced forests | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alvaro Carbonero; Hidde Koerts; Benjamin Moore; Sophie Spirkl | 2023-06-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020082 | GAX-AX_holes_length_divisible_3_detection

Detecting a long even hole | Open Question: Detecting Holes of Length Divisible by Three

论文中定位：Open Question: Detecting Holes of Length Divisible by Three；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Linda Cook; Paul Seymour | 2020-09-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020083 | GAX-AX_hypercube_coloring_1_ball_reconstruction_threshold

Shotgun reconstruction in the hypercube | Gap problem for 1-ball reconstruction threshold

论文中定位：Gap problem for 1-ball reconstruction threshold；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Michał Przykucki; Alexander Roberts; Alex Scott | 2019-07-16

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020084 | GAX-AX_hypercube_statistic_lambda_d_1_limit

On hypercube statistics | Conjecture on $\lambda(d,1)$

论文中定位：Conjecture on $\lambda(d,1)$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Maria Axenovich; John Goldwasser | 2024-10-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020085 | GAX-AX_hypercube_statistic_lambda_tight_bounds

On hypercube statistics | Open problem on tight bounds for $\lambda(d,s)$

论文中定位：Open problem on tight bounds for $\lambda(d,s)$；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Maria Axenovich; John Goldwasser | 2024-10-27

V3-020121 | GAX-AX_kromatic_claw_free_grassmannian_subvariety

The Kromatic Symmetric Function: A K-theoretic Analogue of X_G | Grassmannian Subvariety Construction Problem

论文中定位：Grassmannian Subvariety Construction Problem；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Logan Crew; Oliver Pechenik; Sophie Spirkl | 2023-05-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020122 | GAX-AX_kt_immersion_free_clique_count

On the number of cliques in graphs with a forbidden subdivision or immersion | Conjecture on maximum cliques with no K_t-immersion

论文中定位：Conjecture on maximum cliques with no K_t-immersion；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Fan Wei | 2018-08-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020123 | GAX-AX_kt_minor_free_list_chromatic_2t

Improved lower bound for the list chromatic number of graphs with no K_t minor | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Raphael Steiner | 2021-10-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020124 | GAX-AX_kt_minor_free_universal_graph_separators

Universality in minor-closed graph classes | Open Problem (Section 1): Balanced Separator for U_t

论文中定位：Open Problem (Section 1): Balanced Separator for U_t；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tony Huynh; Bojan Mohar; Robert Šámal; Carsten Thomassen; David R. Wood | 2021-09-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020125 | GAX-AX_kt_subdivision_free_clique_count_exponent

On the number of cliques in graphs with a forbidden subdivision or immersion | Conjecture on optimal exponential constant for K_t-subdivision clique count

论文中定位：Conjecture on optimal exponential constant for K_t-subdivision clique count；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Fan Wei | 2018-08-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020126 | GAX-AX_large_chromatic_dense_minor_edge_density

Dense minors of graphs with independence number two | Informal conjecture on improving the $g(t)$ lower bound

论文中定位：Informal conjecture on improving the $g(t)$ lower bound；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Sergey Norin; Paul Seymour | 2022-06-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020127 | GAX-AX_large_chromatic_induced_path_uniquely_covered

Induced subgraphs of graphs with large chromatic number. IX. Rainbow paths | Question (uniquely-covered vertices in an induced path)

论文中定位：Question (uniquely-covered vertices in an induced path)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2017-07-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020128 | GAX-AX_large_chromatic_rainbow_hole_consecutive_vertices

Induced subgraphs of graphs with large chromatic number. IX. Rainbow paths | Question (rainbow hole with s consecutive rainbow vertices)

论文中定位：Question (rainbow hole with s consecutive rainbow vertices)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2017-07-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020129 | GAX-AX_large_treewidth_unavoidable_induced_subgraphs

Induced subgraphs and tree decompositions XVI. Complete bipartite induced minors | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Sepehr Hajebi; Sophie Spirkl | 2026-02-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020130 | GAX-AX_largest_clique_minor_opt_approximation

A Polynomial-Time Approximation Algorithm for Complete Interval Minors | Open Problem: polytime $f(\mathrm{OPT})$-approximation for largest complete minor

论文中定位：Open Problem: polytime $f(\mathrm{OPT})$-approximation for largest complete minor；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Romain Bourneuf; Julien Cocquet; Chaoliang Tang; Stéphan Thomassé | 2025-05-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020131 | GAX-AX_lattice_cube_list_colorability_threshold

Mixing properties of colorings of the $\mathbb{Z}^d$ lattice | Optimal n for L^d_n-list-colorability

论文中定位：Optimal n for L^d_n-list-colorability；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Raimundo Briceño; Nishant Chandgotia; Alexander Magazinov; Yinon Spinka | 2019-12-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020132 | GAX-AX_layered_treewidth_bounded_queue_number

Minor-closed graph classes with bounded layered pathwidth | Open problem on queue-number of bounded layered treewidth graphs

论文中定位：Open problem on queue-number of bounded layered treewidth graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Vida Dujmović; David Eppstein; Gwenaël Joret; Pat Morin; David R. Wood | 2020-06-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020133 | GAX-AX_linear_equation_free_sets_sqrt_n

The regularity method for graphs with few 4-cycles | Improvement of the bound in Theorem 1.12

论文中定位：Improvement of the bound in Theorem 1.12；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Benny Sudakov; Yufei Zhao | 2021-09-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020134 | GAX-AX_lipschitz_bijection_dictator_xor_inverse

Lipschitz bijections between boolean functions | Informal Question (Section 2)

论文中定位：Informal Question (Section 2)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tom Johnston; Alex Scott | 2021-12-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020135 | GAX-AX_list_chromatic_fraction_delta_small_clique

Bounding $χ$ by a fraction of $Δ$ for graphs without large cliques | Question 1.5

论文中定位：Question 1.5；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Tom Kelly; Peter Nelson; Luke Postle | 2018-03-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020136 | GAX-AX_list_chromatic_reed_bound

Bounding $χ$ by a fraction of $Δ$ for graphs without large cliques | List-chromatic analogue of Reed's Conjecture

论文中定位：List-chromatic analogue of Reed's Conjecture；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Tom Kelly; Peter Nelson; Luke Postle | 2018-03-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020137 | GAX-AX_list_coloring_rp3_free_np_hard

Complexity dichotomy for List-5-Coloring with a forbidden induced subgraph | Open Question: NP-hardness of List-k-Coloring on rP3-free graphs

论文中定位：Open Question: NP-hardness of List-k-Coloring on rP3-free graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Sepehr Hajebi; Yanjia Li; Sophie Spirkl | 2022-08-30

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020138 | GAX-AX_list_decodable_zero_rate_codes_asymptotics

List-decodable zero-rate codes | Informal Conjecture on exact asymptotics of maxcode_L for even L

论文中定位：Informal Conjecture on exact asymptotics of maxcode_L for even L；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Boris Bukh; Yury Polyanskiy | 2018-05-14

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020139 | GAX-AX_list_ramsey_chromatic_family_exact

Multicolor list Ramsey numbers grow exponentially | Conjecture on $R_\ell(\mathcal{H}_s, k)$

论文中定位：Conjecture on $R_\ell(\mathcal{H}_s, k)$；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Xiaoyu He; Sammy Luo; Max Wenqiang Xu | 2022-01-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020140 | GAX-AX_list_ramsey_exponential_constant_k3

Multicolor list Ramsey numbers grow exponentially | Determine the exponential constant in $R_\ell(H,k)$

论文中定位：Determine the exponential constant in $R_\ell(H,k)$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Xiaoyu He; Sammy Luo; Max Wenqiang Xu | 2022-01-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020141 | GAX-AX_local_search_ptas_monotone_fo_optimization

Baker game and polynomial-time approximation schemes | Open Problem (Section 1.1)

论文中定位：Open Problem (Section 1.1)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák | 2019-01-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020142 | GAX-AX_lollipop_active_path_complete_graph_criterion

Lollipops, dense cycles and chords | Question 4.1

论文中定位：Question 4.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Beatriz Martins; Stéphan Thomassé; Nicolas Trotignon | 2025-10-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020143 | GAX-AX_lollipop_active_vertices_optimal_cycle

Lollipops, dense cycles and chords | Question 4.2

论文中定位：Question 4.2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Beatriz Martins; Stéphan Thomassé; Nicolas Trotignon | 2025-10-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020144 | GAX-AX_long_odd_hole_detection_running_time

Detecting a long odd hole | Open Question (running time improvement for long hole detection)

论文中定位：Open Question (running time improvement for long hole detection)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour | 2020-09-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020145 | GAX-AX_long_odd_hole_heavy_path_lemma

Detecting a long odd hole | Informal Conjecture (heavy path extension)

论文中定位：Informal Conjecture (heavy path extension)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour | 2020-09-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020146 | GAX-AX_majority_coloring_digraphs_1_over_k

Majority Colourings of Digraphs | Conjecture 9

论文中定位：Conjecture 9；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020147 | GAX-AX_majority_coloring_digraphs_2_colorable_recognition

Majority Colourings of Digraphs | Open Problem 5

论文中定位：Open Problem 5；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020148 | GAX-AX_majority_coloring_digraphs_3_colors

Majority Colourings of Digraphs | Conjecture 2

论文中定位：Conjecture 2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020149 | GAX-AX_majority_coloring_digraphs_beta_3_colors

Majority Colourings of Digraphs | Open Problem 1

论文中定位：Open Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020150 | GAX-AX_majority_coloring_digraphs_choosability_constant

Majority Colourings of Digraphs | Open Problem 7

论文中定位：Open Problem 7；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020151 | GAX-AX_majority_coloring_digraphs_fractional_weight

Majority Colourings of Digraphs | Open Problem 8

论文中定位：Open Problem 8；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020152 | GAX-AX_majority_coloring_eulerian_digraphs_3_colors

Majority Colourings of Digraphs | Open Problem 3

论文中定位：Open Problem 3；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020153 | GAX-AX_majority_coloring_tournaments_3_colors

Majority Colourings of Digraphs | Open Problem 2

论文中定位：Open Problem 2；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Stephan Kreutzer; Sang-il Oum; Paul Seymour; Dominic van der Zypen; David R. Wood | 2016-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020154 | GAX-AX_meyniel_cop_number_k_uniform_hypergraph

Catching a robber on a random k-uniform hypergraph | Conjecture 1.4

论文中定位：Conjecture 1.4；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Joshua Erde; Mihyun Kang; Florian Lehner; Bojan Mohar; Dominik Schmid | 2024-04-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020155 | GAX-AX_min_degree_3_cycle_linear_chords

Lollipops, dense cycles and chords | Question 4.3

论文中定位：Question 4.3；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Beatriz Martins; Stéphan Thomassé; Nicolas Trotignon | 2025-10-10

V3-020162 | GAX-AX_multicolor_ramsey_3_graph_every_exponent

The growth rate of multicolor Ramsey numbers of 3-graphs | Problem 4.1

论文中定位：Problem 4.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Domagoj Bradač; Jacob Fox; Benny Sudakov | 2024-04-29

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020163 | GAX-AX_multicolor_ramsey_hypergraph_tower_height

The growth rate of multicolor Ramsey numbers of 3-graphs | Problem 1.1

论文中定位：Problem 1.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Domagoj Bradač; Jacob Fox; Benny Sudakov | 2024-04-29

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020164 | GAX-AX_multidimensional_ramsey_r2_superexponential

A multidimensional Ramsey Theorem | Problem 4.1

论文中定位：Problem 4.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | António Girão; Gal Kronenberg; Alex Scott | 2024-12-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020165 | GAX-AX_multidimensional_ramsey_r2_vs_erdos_szekeres

A multidimensional Ramsey Theorem | Problem 4.2

论文中定位：Problem 4.2；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | António Girão; Gal Kronenberg; Alex Scott | 2024-12-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020166 | GAX-AX_multiplicative_group_matrix_rank_sharp_bounds

Rank of matrices with entries from a multiplicative group | Open problem: improved quantitative rank bounds

论文中定位：Open problem: improved quantitative rank bounds；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Jozsef Solymosi | 2021-09-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020167 | GAX-AX_multitasking_capacity_average_degree_log_n

A Graph-Theoretic Approach to Multitasking | Open Problem (multitasker at average degree $\Theta(\log n)$)

论文中定位：Open Problem (multitasker at average degree $\Theta(\log n)$)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Jonathan D. Cohen; Biswadip Dey; Tom Griffiths; Sebastian Musslick; Kayhan Ozcimder; Daniel Reichman; Igor Shinkar; Tal Wagner | 2017-06-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020168 | GAX-AX_multitasking_interference_increases_with_depth

A Graph-Theoretic Approach to Multitasking | Open Problem (interference worsens with depth)

论文中定位：Open Problem (interference worsens with depth)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Jonathan D. Cohen; Biswadip Dey; Tom Griffiths; Sebastian Musslick; Kayhan Ozcimder; Daniel Reichman; Igor Shinkar; Tal Wagner | 2017-06-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020169 | GAX-AX_mwis_long_hole_prism_free_fpt

On the Maximum Weight Independent Set Problem in graphs without induced cycles of length at least five | FPT Algorithm for MWIS in (Long-Hole, k-Prism)-Free Graphs

论文中定位：FPT Algorithm for MWIS in (Long-Hole, k-Prism)-Free Graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Marcin Pilipczuk; Michał Pilipczuk; Stéphan Thomassé | 2020-01-16

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020170 | GAX-AX_mwis_p7_free_complexity

Induced subgraphs of bounded treewidth and the container method | MWIS in P7-free graphs

论文中定位：MWIS in P7-free graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tara Abrishami; Maria Chudnovsky; Marcin Pilipczuk; Paweł Rzążewski; Paul Seymour | 2020-03-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020171 | GAX-AX_mwis_qptas_forest_subdivision_free

Quasi-polynomial time approximation schemes for the Maximum Weight Independent Set Problem in H-free graphs | Conjecture 1.3

论文中定位：Conjecture 1.3；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Marcin Pilipczuk; Michał Pilipczuk; Stéphan Thomassé | 2023-11-14

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020172 | GAX-AX_mycielski_graphs_independence_ratio

Revisiting a theorem by Folkman on graph colouring | Open problem on minimum independence ratio of Mycielski graphs

论文中定位：Open problem on minimum independence ratio of Mycielski graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Pierre Charbit; Oscar Defrain; Gwenaël Joret; Aurélie Lagoutte; Vincent Limouzy; Lucas Pastor; Jean-Sébastien Sereni | 2020-03-23

V3-020173 | GAX-AX_negative_p_energy_path_minimum

Vertex Partitioning and p-Energy of Graphs | Conjecture 2

论文中定位：Conjecture 2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Saieed Akbari; Hitesh Kumar; Bojan Mohar; Shivaramakrishna Pragada | 2025-06-20

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020174 | GAX-AX_neighborhood_complexity_kt_minor_free_polynomial

Neighborhood complexity of planar graphs | Problem 42

论文中定位：Problem 42；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Gwenaël Joret; Clément Rambaud | 2023-12-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020175 | GAX-AX_neighborhood_complexity_planar_tight_bound

Neighborhood complexity of planar graphs | Problem 41

论文中定位：Problem 41；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Gwenaël Joret; Clément Rambaud | 2023-12-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020176 | GAX-AX_non_averaging_sets_n_quarter_tight

Homogeneous structures in subset sums and non-averaging sets | Informal Conjecture on h(n)

论文中定位：Informal Conjecture on h(n)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Huy Tuan Pham | 2023-11-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020177 | GAX-AX_normal_graphs_cover_sizes_max_order

Minimal normal graph covers | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Gajser; Bojan Mohar | 2016-01-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020178 | GAX-AX_normal_graphs_random_gnp_whp

Minimal normal graph covers | Open Question (normality of random graphs)

论文中定位：Open Question (normality of random graphs)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Gajser; Bojan Mohar | 2016-01-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020179 | GAX-AX_ordered_complete_graph_monochromatic_nonnested_matching

Open problems of the 33rd Workshop on Cycles and Colourings | Problem 1.1

论文中定位：Problem 1.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | János Barát; Zdeněk Dvořák; Penny Haxell; František Kardoš; Borut Lužar; Alfréd Onderko; Jozef Rajník; Roman Soták; Nikolay Ulyanov | 2025-11-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020180 | GAX-AX_ordered_pure_pairs_n_polylog

Pure pairs. VII. Homogeneous submatrices in 0/1-matrices with a forbidden submatrix | Informal belief on Conjecture 1.7 and polylog bound

论文中定位：Informal belief on Conjecture 1.7 and polylog bound；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour; Sophie Spirkl | 2021-01-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020181 | GAX-AX_ordered_ramsey_matching_exponent_gap

Ordered Ramsey numbers | Open problem: true ordered Ramsey number of matchings

论文中定位：Open problem: true ordered Ramsey number of matchings；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Choongbum Lee; Benny Sudakov | 2016-04-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020182 | GAX-AX_ordered_ramsey_matching_vs_triangle_order

Ordered Ramsey numbers | Open problem: ordered Ramsey number of matchings vs triangles

论文中定位：Open problem: ordered Ramsey number of matchings vs triangles；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Choongbum Lee; Benny Sudakov | 2016-04-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020183 | GAX-AX_oriented_chi_bounded_forbidden_oriented_star

$χ$-bounded families of oriented graphs | Conjecture 4

论文中定位：Conjecture 4；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Jørgen Bang-Jensen; Nicolas Bousquet; Pierre Charbit; Frédéric Havet; Frédéric Maffray; Jose Zamora | 2016-05-24

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020184 | GAX-AX_oriented_chi_bounded_forbidden_p4_orientations

$χ$-bounded families of oriented graphs | Conjecture 5

论文中定位：Conjecture 5；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Jørgen Bang-Jensen; Nicolas Bousquet; Pierre Charbit; Frédéric Havet; Frédéric Maffray; Jose Zamora | 2016-05-24

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020185 | GAX-AX_oriented_tree_avoiding_2_coloring_complexity

Colorings of oriented planar graphs avoiding a monochromatic subgraph | Open Complexity Problem (2-F-PFC for oriented trees of maximum degree ≥ 3)

论文中定位：Open Complexity Problem (2-F-PFC for oriented trees of maximum degree ≥ 3)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Helena Bergold; Winfried Hochstättler; Raphael Steiner | 2022-06-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020186 | GAX-AX_p_entropic_matroids_prime_representable

Entropic matroids and their representation | Open problem: p-entropic matroids linear for prime p

论文中定位：Open problem: p-entropic matroids linear for prime p；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Emmanuel Abbe; Sophie Spirkl | 2019-09-26

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020187 | GAX-AX_padded_strings_unavoidable_substring_sets

Induced subgraphs and tree decompositions XIII. Basic obstructions in $\mathcal{H}$-free graphs for finite $\mathcal{H}$ | Question 8.3

论文中定位：Question 8.3；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bogdan Alecu; Maria Chudnovsky; Sepehr Hajebi; Sophie Spirkl | 2024-11-26

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020188 | GAX-AX_partial_grundy_coloring_parameterized_complexity

Grundy Coloring & friends, Half-Graphs, Bicliques | Parameterized complexity of Partial Grundy Coloring on general graphs

论文中定位：Parameterized complexity of Partial Grundy Coloring on general graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Pierre Aboulker; Édouard Bonnet; Eun Jung Kim; Florian Sikora | 2020-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020189 | GAX-AX_path_free_polynomial_chi_tau_d

Polynomial bounds for chromatic number. V. Excluding a tree of radius two and a complete multipartite graph | Question: Extending Theorem 1.6 to paths

论文中定位：Question: Extending Theorem 1.6 to paths；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2023-01-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020190 | GAX-AX_perfect_graphs_combinatorial_independent_set_algorithm

The independent set problem is FPT for even-hole-free graphs | Open problem: Combinatorial algorithm for MIS on perfect graphs

论文中定位：Open problem: Combinatorial algorithm for MIS on perfect graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Edin Husic; Stephan Thomasse; Nicolas Trotignon | 2019-10-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020191 | GAX-AX_perfect_graphs_combinatorial_mis_algorithm

On the Maximum Weight Independent Set Problem in graphs without induced cycles of length at least five | Combinatorial Polynomial-Time Algorithm for MIS/MWIS in Perfect Graphs

论文中定位：Combinatorial Polynomial-Time Algorithm for MIS/MWIS in Perfect Graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Marcin Pilipczuk; Michał Pilipczuk; Stéphan Thomassé | 2020-01-16

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020192 | GAX-AX_perfect_graphs_combinatorial_mwis_algorithm

Induced subgraphs of bounded treewidth and the container method | Combinatorial polynomial-time algorithm for MWIS in perfect graphs

论文中定位：Combinatorial polynomial-time algorithm for MWIS in perfect graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tara Abrishami; Maria Chudnovsky; Marcin Pilipczuk; Paweł Rzążewski; Paul Seymour | 2020-03-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020193 | GAX-AX_perfect_graphs_tight_skew_partitions_count

Colouring perfect graphs with bounded clique number | Open Question on Number of Tight Skew Partitions

论文中定位：Open Question on Number of Tight Skew Partitions；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Aurélie Lagoutte; Paul Seymour; Sophie Spirkl | 2017-07-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020194 | GAX-AX_perfect_matching_flip_switchable_recognition

The Perfect Matching Reconfiguration Problem | Open Question: Recognition of Switchable Graphs

论文中定位：Open Question: Recognition of Switchable Graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Nicolas Bousquet; Marc Heinrich; Takehiro Ito; Yusuke Kobayashi; Arnaud Mary; Moritz Mühlenthaler; Kunihiro Wasa | 2019-04-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020195 | GAX-AX_permutation_property_testing_query_bounds

Fast property testing and metrics for permutations | Open Problem (better query complexity bounds for property testing)

论文中定位：Open Problem (better query complexity bounds for property testing)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Fan Wei | 2018-04-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020196 | GAX-AX_planar_c4_c5_fractional_chromatic_11_3

Planar graphs without cycles of length 4 or 5 are (11:3)-colorable | Informal conjecture on optimality of 11/3

论文中定位：Informal conjecture on optimality of 11/3；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Xiaolan Hu | 2019-07-14

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020197 | GAX-AX_planar_c4_c7_free_3_choosable

Correspondence coloring and its application to list-coloring planar graphs without cycles of lengths 4 to 8 | Open Question on 3-Choosability for Forbidden Cycles 4-7 and 4-6

论文中定位：Open Question on 3-Choosability for Forbidden Cycles 4-7 and 4-6；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Luke Postle | 2016-10-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020198 | GAX-AX_planar_c4_c8_free_correspondence_coloring

Correspondence coloring and its application to list-coloring planar graphs without cycles of lengths 4 to 8 | Informal Conjecture on Correspondence Chromatic Number of Planar Graphs Without Cycles 4-8

论文中定位：Informal Conjecture on Correspondence Chromatic Number of Planar Graphs Without Cycles 4-8；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Luke Postle | 2016-10-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020199 | GAX-AX_planar_cover_graph_poset_dimension_height

Planar posets have dimension at most linear in their height | Open problem: dimension of posets with planar cover graphs vs. height

论文中定位：Open problem: dimension of posets with planar cover graphs vs. height；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Gwenaël Joret; Piotr Micek; Veit Wiechert | 2017-09-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020200 | GAX-AX_planar_expansions_edge_erdos_posa

Erdős-Pósa from ball packing | Open Problem (edge-EP property characterization for planar graph expansions)

论文中定位：Open Problem (edge-EP property characterization for planar graph expansions)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Wouter Cames van Batenburg; Gwenaël Joret; Arthur Ulmer | 2020-06-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020201 | GAX-AX_planar_independence_number_n_over_4

Triangle-free planar graphs with small independence number | Open Problem (independence number of planar graphs)

论文中定位：Open Problem (independence number of planar graphs)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Jordan Venters | 2017-02-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020202 | GAX-AX_planar_recoloring_linear_diameter_min_colors

An update on reconfiguring 10-colorings of planar graphs | Problem 3

论文中定位：Problem 3；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Carl Feghali | 2020-02-13

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020203 | GAX-AX_planar_weak_coloring_number_quadratic_log

Improved bounds for weak coloring numbers | Conjecture 4

论文中定位：Conjecture 4；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Gwenaël Joret; Piotr Micek | 2022-03-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020204 | GAX-AX_plane_graphs_weak_diameter_2_coloring

Weak diameter coloring of graphs on surfaces | Question 6

论文中定位：Question 6；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Sergey Norin | 2021-11-13

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020205 | GAX-AX_plane_triangle_free_distant_precoloring_extension

Three-coloring triangle-free graphs on surfaces V. Coloring planar graphs with distant anomalies | Conjecture 1.4

论文中定位：Conjecture 1.4；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Daniel Kral; Robin Thomas | 2020-04-15

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020206 | GAX-AX_poly_chi_bounded_forests_known_complete

Polynomial bounds for chromatic number. II. Excluding a star-forest | Informal remark on completeness of known forests satisfying Esperet's conjecture

论文中定位：Informal remark on completeness of known forests satisfying Esperet's conjecture；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour; Sophie Spirkl | 2021-07-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020207 | GAX-AX_poly_chi_bounded_odd_multihole_free

Polynomial bounds for chromatic number VII. Disjoint holes | Open problem (poly-χ-bounded for k-multihole with only odd cycles)

论文中定位：Open problem (poly-χ-bounded for k-multihole with only odd cycles)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2022-02-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020208 | GAX-AX_poly_chi_bounded_self_isolating_all

Polynomial bounds for chromatic number VII. Disjoint holes | Question (are all graphs self-isolating?)

论文中定位：Question (are all graphs self-isolating?)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2022-02-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020209 | GAX-AX_poly_chi_bounded_trees_disjoint_union

Polynomial bounds for chromatic number VII. Disjoint holes | Open problem (disjoint union of good trees)

论文中定位：Open problem (disjoint union of good trees)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2022-02-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020210 | GAX-AX_polynomial_expansion_balanced_separator_constant_m

On classes of graphs with strongly sublinear separators | Informal Conjecture (constant-size M)

论文中定位：Informal Conjecture (constant-size M)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák | 2018-02-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020211 | GAX-AX_polynomial_expansion_bounded_twin_width_speculation

Twin-width I: tractable FO model checking | Informal Conjecture (polynomial expansion and bounded twin-width)

论文中定位：Informal Conjecture (polynomial expansion and bounded twin-width)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Édouard Bonnet; Eun Jung Kim; Stéphan Thomassé; Rémi Watrigant | 2021-10-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020212 | GAX-AX_popular_progression_tower_height_small_primes

Popular progression differences in vector spaces II | Conjecture (Theorem 2 extends to primes p < 19)

论文中定位：Conjecture (Theorem 2 extends to primes p < 19)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Huy Tuan Pham | 2019-11-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020213 | GAX-AX_positive_square_energy_lower_bound_4n_5

A Linear Lower Bound for the Square Energy of Graphs | Informal Conjecture (improved linear bound)

论文中定位：Informal Conjecture (improved linear bound)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Saieed Akbari; Hitesh Kumar; Bojan Mohar; Shivaramakrishna Pragada | 2024-09-26

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020214 | GAX-AX_prime_cayley_graph_finite_ring_characterization

On prime Cayley graphs | Question 4.28

论文中定位：Question 4.28；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Michal Cizek; Logan Crew; Ján Mináč; Tung T. Nguyen; Sophie Spirkl; Nguyên Duy Tân | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020215 | GAX-AX_prime_cayley_graph_joined_union_decomposition

On prime Cayley graphs | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Michal Cizek; Logan Crew; Ján Mináč; Tung T. Nguyen; Sophie Spirkl; Nguyên Duy Tân | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020216 | GAX-AX_prime_cayley_graph_tensor_product_complete

On prime Cayley graphs | Question 4.31

论文中定位：Question 4.31；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Michal Cizek; Logan Crew; Ján Mináč; Tung T. Nguyen; Sophie Spirkl; Nguyên Duy Tân | 2024-01-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020217 | GAX-AX_prism_pyramid_theta_turtle_free_separators

Maximum independent sets in (pyramid, even hole)-free graphs | Conjecture 2.2

论文中定位：Conjecture 2.2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Stéphan Thomassé; Nicolas Trotignon; Kristina Vušković | 2019-12-24

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020218 | GAX-AX_prism_pyramid_theta_wheel_free_separators

Maximum independent sets in (pyramid, even hole)-free graphs | Open problem: polynomial separator property for (prism, pyramid, theta, even wheel)-free graphs

论文中定位：Open problem: polynomial separator property for (prism, pyramid, theta, even wheel)-free graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Stéphan Thomassé; Nicolas Trotignon; Kristina Vušković | 2019-12-24

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020219 | GAX-AX_properly_colored_kn_longest_rainbow_cycle

Random subgraphs of properly edge-coloured complete graphs and long rainbow cycles | Open Problem: error term for longest rainbow cycle

论文中定位：Open Problem: error term for longest rainbow cycle；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Alexey Pokrovskiy; Benny Sudakov | 2016-08-25

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020220 | GAX-AX_pt_free_3_coloring_polynomial_all_t

List-three-coloring graphs with no induced P_6+rP_3 | Question 1.1

论文中定位：Question 1.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Shenwei Huang; Sophie Spirkl; Mingxian Zhong | 2018-07-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020221 | GAX-AX_pt_free_3_coloring_polynomial_large_t

H-colouring P_t-free graphs in subexponential time | Open Problem: Complexity of 3-colourability of P_t-free graphs

论文中定位：Open Problem: Complexity of 3-colourability of P_t-free graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Carla Groenland; Karolina Okrasa; Pawel Rzążewski; Alex Scott; Paul Seymour; Sophie Spirkl | 2019-03-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020222 | GAX-AX_pt_free_3_coloring_polynomial_linear_forests

List-k-Coloring H-free graphs for all $k>4$ | Converse to Theorem 1.1 (3-Coloring dichotomy for H-free graphs)

论文中定位：Converse to Theorem 1.1 (3-Coloring dichotomy for H-free graphs)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Sepehr Hajebi; Sophie Spirkl | 2023-11-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020223 | GAX-AX_pt_free_independent_set_polynomial_t_7

H-colouring P_t-free graphs in subexponential time | Open Problem: Polynomial-time maximum independent set on P_t-free graphs

论文中定位：Open Problem: Polynomial-time maximum independent set on P_t-free graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Carla Groenland; Karolina Okrasa; Pawel Rzążewski; Alex Scott; Paul Seymour; Sophie Spirkl | 2019-03-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020224 | GAX-AX_pure_pairs_blockade_polynomial_ordered_graphs

Pure pairs. IX. Transversal trees | Informal: which graphs H admit polynomial-size pure pairs

论文中定位：Informal: which graphs H admit polynomial-size pure pairs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour; Sophie Spirkl | 2024-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020225 | GAX-AX_pure_pairs_blockade_strong_transversal_characterization

Pure pairs. IX. Transversal trees | Informal: characterization of graphs with the strong transversal property

论文中定位：Informal: characterization of graphs with the strong transversal property；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour; Sophie Spirkl | 2024-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020226 | GAX-AX_pure_pairs_blockade_transversal_triangle_polynomial

Pure pairs. IX. Transversal trees | Question 1.3

论文中定位：Question 1.3；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour; Sophie Spirkl | 2024-02-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020227 | GAX-AX_quantum_ergodicity_small_spectral_window

High-girth near-Ramanujan graphs with localized eigenvectors | Open problem on quantum ergodicity over small spectral windows (Remark 1.2)

论文中定位：Open problem on quantum ergodicity over small spectral windows (Remark 1.2)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Shirshendu Ganguly; Nikhil Srivastava | 2019-08-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020228 | GAX-AX_quantum_sorting_poset_lower_bounds_equivalent

Information-theoretic lower bounds for quantum sorting | Conjecture on LB and QLB equivalence

论文中定位：Conjecture on LB and QLB equivalence；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jean Cardinal; Gwenaël Joret; Jérémie Roland | 2019-02-18

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020229 | GAX-AX_quartic_eulerian_digraphs_diplanar_obstructions

Embedding Quartic Eulerian Digraphs on the Plane | Problem 1.2

论文中定位：Problem 1.2；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Dan Archdeacon; Paul Bonnington; Bojan Mohar | 2017-06-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020230 | GAX-AX_quasi_isometry_multiplicative_to_additive_classes

Asymptotic structure. II. Path-width and additive quasi-isometry | Conjecture 1.2

论文中定位：Conjecture 1.2；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tung Nguyen; Alex Scott; Paul Seymour | 2025-10-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020231 | GAX-AX_rainbow_stacking_odd_complete_proper_colorings

Rainbow Stackings of Random Edge-Colorings | Question 3.3

论文中定位：Question 3.3；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Colin Defant; Noah Kravitz | 2024-05-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020232 | GAX-AX_rainbow_stacking_random_colorings_sharp_threshold

Rainbow Stackings of Random Edge-Colorings | Problem 3.1

论文中定位：Problem 3.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Colin Defant; Noah Kravitz | 2024-05-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020233 | GAX-AX_ramsey_sqrt_edges_bound_multicolor

Ramsey numbers of hypergraphs of a given size | Informal Problem: extending the $\sqrt{m}$ Ramsey bound to more than two colors for graphs

论文中定位：Informal Problem: extending the $\sqrt{m}$ Ramsey bound to more than two colors for graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Domagoj Bradač; Jacob Fox; Benny Sudakov | 2023-08-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020234 | GAX-AX_random_4_regular_graph_polynomial_coefficient

Open problems of the 33rd Workshop on Cycles and Colourings | Problem 2.1

论文中定位：Problem 2.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | János Barát; Zdeněk Dvořák; Penny Haxell; František Kardoš; Borut Lužar; Alfréd Onderko; Jozef Rajník; Roman Soták; Nikolay Ulyanov | 2025-11-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020235 | GAX-AX_random_graph_hereditary_extremal_bipartite_asymptotics

Largest subgraph from a hereditary property in a random graph | Open Problem (accurate estimate in the bipartite case)

论文中定位：Open Problem (accurate estimate in the bipartite case)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Michael Krivelevich; Wojciech Samotij | 2022-10-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020236 | GAX-AX_random_graph_hereditary_extremal_polynomial_saving

Largest subgraph from a hereditary property in a random graph | Informal Conjecture (polynomial saving in the bipartite case)

论文中定位：Informal Conjecture (polynomial saving in the bipartite case)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Michael Krivelevich; Wojciech Samotij | 2022-10-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020237 | GAX-AX_random_graph_hereditary_extremal_probability_range

Largest subgraph from a hereditary property in a random graph | Open Problem (characterizing edge probabilities for Theorem 1.1)

论文中定位：Open Problem (characterizing edge probabilities for Theorem 1.1)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Michael Krivelevich; Wojciech Samotij | 2022-10-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020238 | GAX-AX_random_irregular_subgraph_property_range

On random irregular subgraphs | Informal Conjecture on Property (*) for d = o(n/log n)

论文中定位：Informal Conjecture on Property (*) for d = o(n/log n)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Sammy Luo; Huy Tuan Pham | 2022-07-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020239 | GAX-AX_regular_4_critical_no_critical_edge

Critical edge sets in vertex-critical graphs | Problem 5.2

论文中定位：Problem 5.2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Ema Skottova; Raphael Steiner | 2025-08-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020240 | GAX-AX_regular_independence_edge_deletion_cubic_infinite

A Counterexample to a Conjecture of Lovász | Question 4.1

论文中定位：Question 4.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alexander Clow; Penny Haxell; Bojan Mohar | 2025-06-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020241 | GAX-AX_restricted_difference_3_ap_free_density

A note on arithmetic progressions with restricted differences | Problem 8

论文中定位：Problem 8；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Huy Tuan Pham | 2026-05-13

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020242 | GAX-AX_restricted_difference_triangle_removal_lemma

A note on arithmetic progressions with restricted differences | Problem 9

论文中定位：Problem 9；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Huy Tuan Pham | 2026-05-13

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020243 | GAX-AX_rodl_h_free_restricted_union_cover

Strengthening Rodl's theorem | Union cover variant (open problem)

论文中定位：Union cover variant (open problem)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2022-08-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020244 | GAX-AX_runsort_permuton_horizontal_uniformity_direct

The runsort permuton | Direct Proof of Horizontal Uniformity

论文中定位：Direct Proof of Horizontal Uniformity；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Colin Defant; Noah Kravitz | 2021-06-28

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020245 | GAX-AX_ryser_near_extremal_hypergraphs_projective_planes

A note on intersecting hypergraphs with large cover number | Informal Problem (projective plane structure in near-extremal constructions)

论文中定位：Informal Problem (projective plane structure in near-extremal constructions)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Penny Haxell; Alex Scott | 2017-10-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020246 | GAX-AX_separable_index_parameterized_complexity

Factoring Pattern-Free Permutations into Separable ones | Question 1.3

论文中定位：Question 1.3；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Édouard Bonnet; Romain Bourneuf; Colin Geniet; Stéphan Thomassé | 2023-08-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020247 | GAX-AX_separable_index_pattern_avoiding_polynomial

Factoring Pattern-Free Permutations into Separable ones | Question 1.2

论文中定位：Question 1.2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Édouard Bonnet; Romain Bourneuf; Colin Geniet; Stéphan Thomassé | 2023-08-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020248 | GAX-AX_separating_path_system_rainbow_cover_linear

Separating the edges of a graph by a linear number of paths | Problem 4

论文中定位：Problem 4；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Fábio Botler; François Dross; Tássio Naia; Jozef Skokan | 2023-10-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020249 | GAX-AX_separating_path_system_strong_2n

Separating the edges of a graph by a linear number of paths | Problem 3

论文中定位：Problem 3；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Fábio Botler; François Dross; Tássio Naia; Jozef Skokan | 2023-10-10

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020250 | GAX-AX_set_coloring_ramsey_chromatic_variant_equality

Set-coloring Ramsey numbers via codes | Informal Conjecture on R(n;r,s) vs R'(n;r,s) near Turán density

论文中定位：Informal Conjecture on R(n;r,s) vs R'(n;r,s) near Turán density；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Xiaoyu He; Dhruv Mubayi; Andrew Suk; Jacques Verstraete | 2022-06-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020251 | GAX-AX_set_coloring_ramsey_zero_rate_equality

Set-coloring Ramsey numbers and error-correcting codes near the zero-rate threshold | Informal Conjecture (Equality in Theorem 1.1 near the zero-rate threshold)

论文中定位：Informal Conjecture (Equality in Theorem 1.1 near the zero-rate threshold)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Huy Tuan Pham; Yufei Zhao | 2023-08-14

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020252 | GAX-AX_set_mapping_theorem_l_equals_1

Short proofs of some extremal results II | Open Problem: Reducing l to 1 in the Set Mapping Theorem

论文中定位：Open Problem: Reducing l to 1 in the Set Mapping Theorem；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | David Conlon; Jacob Fox; Benny Sudakov | 2016-02-11

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020253 | GAX-AX_shortest_even_hole_detection

Detecting a long even hole | Open Problem: Finding a Shortest Even Hole

论文中定位：Open Problem: Finding a Shortest Even Hole；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Linda Cook; Paul Seymour | 2020-09-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020254 | GAX-AX_shotgun_assembly_second_threshold_all_radii

Shotgun assembly of random graphs | Informal Conjecture (second phase transition for all radii)

论文中定位：Informal Conjecture (second phase transition for all radii)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tom Johnston; Gal Kronenberg; Alexander Roberts; Alex Scott | 2025-06-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020255 | GAX-AX_shotgun_assembly_second_threshold_radius_2

Shotgun assembly of random graphs | Question

论文中定位：Question；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tom Johnston; Gal Kronenberg; Alexander Roberts; Alex Scott | 2025-06-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020256 | GAX-AX_single_conflict_coloring_degenerate_log_n

Single-conflict colouring | Informal conjecture on single-conflict chromatic number of degenerate graphs

论文中定位：Informal conjecture on single-conflict chromatic number of degenerate graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Louis Esperet; Ross J. Kang; Kenta Ozeki | 2020-10-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020257 | GAX-AX_single_conflict_coloring_euler_genus_sqrt

Single-conflict colouring | Conjecture 3

论文中定位：Conjecture 3；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Louis Esperet; Ross J. Kang; Kenta Ozeki | 2020-10-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020258 | GAX-AX_spanning_trees_pivot_gray_code

A Gray code for arborescences of tournaments | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Michael Hoffmann; Clément Legrand-Duchesne; Günter Rote | 2026-03-30

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020259 | GAX-AX_sparse_neighborhoods_chromatic_below_delta

Colouring Graphs with Sparse Neighbourhoods: Bounds and Applications | Question 1.4

论文中定位：Question 1.4；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Thomas Perrett; Luke Postle | 2018-10-15

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020260 | GAX-AX_sparse_neighborhoods_critical_bounded_clique

Colouring Graphs with Sparse Neighbourhoods: Bounds and Applications | Question 1.3

论文中定位：Question 1.3；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Thomas Perrett; Luke Postle | 2018-10-15

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020261 | GAX-AX_spectrally_symmetric_graph_edge_density

Spectrally symmetric orientations of graphs | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Saieed Akbari; Jonathan Aloni; Maxwell Levit; Bojan Mohar; Steven Xia | 2025-12-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020262 | GAX-AX_split_digraph_strong_2_kernel_half

Distant digraph domination | Open question on strong 2-kernels in split digraphs

论文中定位：Open question on strong 2-kernels in split digraphs；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tung Nguyen; Alex Scott; Paul Seymour | 2024-09-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020263 | GAX-AX_strong_coloring_number_bramble_polynomial_expansion

Shallow brambles | Question 2

论文中定位：Question 2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Nicolas Bousquet; Wouter Cames van Batenburg; Louis Esperet; Gwenaël Joret; Piotr Micek | 2025-09-15

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020264 | GAX-AX_strong_coloring_numbers_tame_representation

Sublinear separators in intersection graphs of convex shapes | Question 6

论文中定位：Question 6；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Rose McCarty; Sergey Norin | 2020-01-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020265 | GAX-AX_strong_coloring_numbers_tame_representation_negative

Sublinear separators in intersection graphs of convex shapes | Informal conjecture: negative answer to Question 6

论文中定位：Informal conjecture: negative answer to Question 6；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Rose McCarty; Sergey Norin | 2020-01-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020266 | GAX-AX_structured_graph_codes_f2c_odd_n

Structured Codes of Graphs | Open case of Theorem 3 for odd n

论文中定位：Open case of Theorem 3 for odd n；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Anna Gujgiczer; János Körner; Aleksa Milojević; Gábor Simonyi | 2022-04-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020267 | GAX-AX_subdigraph_half_vertices_min_outdegree_gap

Subdigraphs of prescribed size and outdegree | Open problem: closing the gap for $d(s)$

论文中定位：Open problem: closing the gap for $d(s)$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Raphael Steiner | 2022-10-23

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020268 | GAX-AX_subdivision_free_chi_bounded_multigraph_characterization

Induced subgraphs of graphs with large chromatic number. VI. Banana trees | Open Question: first pervasiveness characterisation

论文中定位：Open Question: first pervasiveness characterisation；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2019-08-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020269 | GAX-AX_sublinear_separator_expansion_exponent_exact

A note on sublinear separators and expansion | Informal open question on the exact value of b_ε

论文中定位：Informal open question on the exact value of b_ε；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák | 2020-07-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020270 | GAX-AX_sublinear_separator_expansion_exponent_one_sided

A note on sublinear separators and expansion | Informal conjecture $b'_\varepsilon = b_\varepsilon$ for $0<\varepsilon<\tfrac{1}{2}$

论文中定位：Informal conjecture $b'_\varepsilon = b_\varepsilon$ for $0<\varepsilon<\tfrac{1}{2}$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák | 2020-07-07

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020271 | GAX-AX_sublinear_separators_fractional_treewidth_fragile

Approximation metatheorems for classes with bounded expansion | Informal Conjecture (fractional treewidth-fragility of sublinear-separator classes)

论文中定位：Informal Conjecture (fractional treewidth-fragility of sublinear-separator classes)；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák | 2021-10-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020272 | GAX-AX_sublinear_separators_product_structure_tree_depth

Product structure of graph classes with strongly sublinear separators | Conjecture (product structure with bounded tree-depth and tight clique size)

论文中定位：Conjecture (product structure with bounded tree-depth and tight clique size)；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; David R. Wood | 2023-09-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020273 | GAX-AX_sublinear_separators_product_structure_treewidth

Product structure of graph classes with strongly sublinear separators | Open Problem 6

论文中定位：Open Problem 6；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; David R. Wood | 2023-09-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020274 | GAX-AX_sun_free_graphs_chi_bounded

Suns in triangle-free graphs of large chromatic number | Informal conjecture on sun-free χ-boundedness without net exclusion

论文中定位：Informal conjecture on sun-free χ-boundedness without net exclusion；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Sepehr Hajebi; Sophie Spirkl | 2026-03-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020275 | GAX-AX_surface_excluded_minors_hoppers_exist

Excluded minors for the Klein Bottle I. Low connectivity case | Informal Conjecture on Existence of Hoppers for Large Euler Genus

论文中定位：Informal Conjecture on Existence of Hoppers for Large Euler Genus；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Bojan Mohar; Petr Škoda | 2020-02-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020276 | GAX-AX_surface_triangle_free_3_coloring_linear

Three-coloring triangle-free graphs on surfaces VII. A linear-time algorithm | Open Problem (linear-time 3-coloring output)

论文中定位：Open Problem (linear-time 3-coloring output)；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdenek Dvorak; Daniel Kral; Robin Thomas | 2020-11-05

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020277 | GAX-AX_tea_sharing_optimal_sequence_exponential_length

Sharing tea on a graph | Question 6.1

论文中定位：Question 6.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | J. Pascal Gollin; Kevin Hendrey; Hao Huang; Tony Huynh; Bojan Mohar; Sang-il Oum; Ningyuan Yang; Wei-Hsuan Yu; Xuding Zhu | 2025-09-22

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020278 | GAX-AX_ternary_graphs_3_colorable

Proof of the Kalai-Meshulam conjecture | Open Problem: 3-colourability of ternary graphs

论文中定位：Open Problem: 3-colourability of ternary graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2018-09-28

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020279 | GAX-AX_theta_triangle_free_bounded_degree_treewidth

(Theta, triangle)-free and (even hole, K_4)-free graphs. Part 2 : bounds on treewidth | Open Question: (theta, triangle)-free graphs of bounded degree

论文中定位：Open Question: (theta, triangle)-free graphs of bounded degree；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marcin Pilipczuk; Ni Luh Dewi Sintiari; Stéphan Thomassé; Nicolas Trotignon | 2020-10-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020280 | GAX-AX_thin_overlays_sublinear_separators_unbounded_degree

Thin graph classes and polynomial-time approximation schemes | Informal Conjecture (Section 1.2): dropping bounded-degree assumption

论文中定位：Informal Conjecture (Section 1.2): dropping bounded-degree assumption；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák | 2017-04-01

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020281 | GAX-AX_token_sliding_chordal_clique_tree_degree

Token Sliding on Chordal Graphs | Question 1

论文中定位：Question 1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marthe Bonamy; Nicolas Bousquet | 2016-05-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020282 | GAX-AX_topological_minor_free_treewidth_product_structure

The grid-minor theorem revisited | Question 2

论文中定位：Question 2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Vida Dujmović; Robert Hickingbotham; Jędrzej Hodor; Gweanël Joret; Hoang La; Piotr Micek; Pat Morin; Clément Rambaud; David R. Wood | 2023-07-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020283 | GAX-AX_tournament_color_avoiding_path_non_transitive

Color-avoiding directed paths in tournaments | Problem 5.1

论文中定位：Problem 5.1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Benny Sudakov; Yuval Wigderson | 2026-01-21

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020284 | GAX-AX_tournament_path_powers_exponent_constant

Powers of paths in tournaments | Open Problem: exact constant in the exponent

论文中定位：Open Problem: exact constant in the exponent；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Nemanja Draganić; François Dross; Jacob Fox; António Girão; Frédéric Havet; Dániel Korándi; William Lochet; David Munhá Correia; Alex Scott; Benny Sudakov | 2021-02-16

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020285 | GAX-AX_tournament_strong_eh_backedge_forest

Pure pairs. X. Tournaments and the strong Erdos-Hajnal property | Conjecture 1.5

论文中定位：Conjecture 1.5；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2023-08-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020286 | GAX-AX_tournament_strong_eh_three_backedges_d5

Pure pairs. X. Tournaments and the strong Erdos-Hajnal property | Informal question: can the D5-freeness hypothesis in Theorem 1.6 be dropped?

论文中定位：Informal question: can the D5-freeness hypothesis in Theorem 1.6 be dropped?；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Maria Chudnovsky; Alex Scott; Paul Seymour; Sophie Spirkl | 2023-08-08

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020287 | GAX-AX_tree_decomposition_edge_connectivity_leaf_count

Edge-partitioning 3-edge-connected graphs into paths | Conjecture 5

论文中定位：Conjecture 5；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Tereza Klimošová; Stéphan Thomassé | 2019-07-26

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020288 | GAX-AX_tree_pathwidth_path_partition_height_2k

Pathwidth and nonrepetitive list coloring | Optimality of factor 2 in Lemma 4

论文中定位：Optimality of factor 2 in Lemma 4；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Adam Gągol; Gwenaël Joret; Jakub Kozik; Piotr Micek | 2016-10-02

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020289 | GAX-AX_treedepth_bound_treewidth_binary_tree_path

Tight bound on treedepth in terms of pathwidth and longest path | Open Problem: sharpness of the treedepth bound in Theorem 1

论文中定位：Open Problem: sharpness of the treedepth bound in Theorem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Meike Hatzel; Gwenaël Joret; Piotr Micek; Marcin Pilipczuk; Torsten Ueckerdt; Bartosz Walczak | 2023-11-06

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020290 | GAX-AX_treewidth_fragile_weighted_vertex_cover_ptas

Approximation schemes for bounded distance problems on fractionally treewidth-fragile graphs | Open Problem: PTAS for weighted minimization problems in fractionally treewidth-fragile classes

论文中定位：Open Problem: PTAS for weighted minimization problems in fractionally treewidth-fragile classes；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Abhiruk Lahiri | 2021-05-04

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020291 | GAX-AX_triangle_free_planar_3_coloring_requests

Do triangle-free planar graphs have exponentially many 3-colorings? | Problem 1

论文中定位：Problem 1；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Jean-Sébastien Sereni | 2017-09-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020292 | GAX-AX_triangle_free_planar_fractional_chromatic_bound

Triangle-free planar graphs with the smallest independence number | Fractional Chromatic Number Bound for Planar Triangle-Free Graphs

论文中定位：Fractional Chromatic Number Bound for Planar Triangle-Free Graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Zdeněk Dvořák; Tomáš Masařík; Jan Musílek; Ondřej Pangrác | 2016-06-20

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020293 | GAX-AX_triangle_removal_vs_dfl_growth

Removal lemmas and approximate homomorphisms | Informal Conjecture on similar growth of $N_{DFL}(\varepsilon)$ and $1/\delta_{TRL}(\varepsilon)$

论文中定位：Informal Conjecture on similar growth of $N_{DFL}(\varepsilon)$ and $1/\delta_{TRL}(\varepsilon)$；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Jacob Fox; Yufei Zhao | 2022-01-13

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020294 | GAX-AX_triangle_s123_free_cliquewidth

(Theta, triangle)-free and (even hole, K_4)-free graphs. Part 2 : bounds on treewidth | Open Question: (triangle, S1,2,3)-free graphs cliquewidth

论文中定位：Open Question: (triangle, S1,2,3)-free graphs cliquewidth；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Marcin Pilipczuk; Ni Luh Dewi Sintiari; Stéphan Thomassé; Nicolas Trotignon | 2020-10-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020295 | GAX-AX_turan_h_free_bounded_matching_number

Turán graphs with bounded matching number | Extension to H-free graphs

论文中定位：Extension to H-free graphs；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Peter Frankl | 2022-10-26

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020296 | GAX-AX_twin_width_approximation_unordered_graphs

Twin-width VI: the lens of contraction sequences | Open Challenge: Efficient Approximation of Twin-Width for Unordered Graphs

论文中定位：Open Challenge: Efficient Approximation of Twin-Width for Unordered Graphs；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Édouard Bonnet; Eun Jung Kim; Amadeus Reinald; Stéphan Thomassé | 2022-05-31

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020297 | GAX-AX_twin_width_connected_domination_no_kernel

Twin-width and polynomial kernels | Open problem: no-kernel lower bound at twin-width 4 for Connected/Total k-Dominating Set

论文中定位：Open problem: no-kernel lower bound at twin-width 4 for Connected/Total k-Dominating Set；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Édouard Bonnet; Eun Jung Kim; Amadeus Reinald; Stéphan Thomassé; Rémi Watrigant | 2021-09-14

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020298 | GAX-AX_twin_width_matrices_infinite_fields

Twin-width V: linear minors, modular counting, and matrix multiplication | Open question on twin-width over infinite fields

论文中定位：Open question on twin-width over infinite fields；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Édouard Bonnet; Ugo Giocanti; Patrice Ossona de Mendez; Stéphan Thomassé | 2022-09-24

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020299 | GAX-AX_twin_width_mis_dominating_approximability

Twin-width III: Max Independent Set, Min Dominating Set, and Coloring | Informal conjecture on MIS approximability vs. Min Dominating Set

论文中定位：Informal conjecture on MIS approximability vs. Min Dominating Set；类型：Informal。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Édouard Bonnet; Colin Geniet; Eun Jung Kim; Stéphan Thomassé; Rémi Watrigant | 2021-02-12

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020300 | GAX-AX_vantage_protrusive_ordering_5_points

Ordering Candidates via Vantage Points | Five-point protrusive-but-not-witnessed construction

论文中定位：Five-point protrusive-but-not-witnessed construction；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Colin Defant; Noah Kravitz; Daniel G. Zhu | 2023-08-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020301 | GAX-AX_vantage_sign_patterns_r_dependence_gap

Ordering Candidates via Vantage Points | Gap in r-dependence of sign-pattern bound

论文中定位：Gap in r-dependence of sign-pattern bound；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Colin Defant; Noah Kravitz; Daniel G. Zhu | 2023-08-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020302 | GAX-AX_vantage_square_roots_sum_components_gap

Ordering Candidates via Vantage Points | Gap in connected-component count for sums of square roots

论文中定位：Gap in connected-component count for sums of square roots；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Noga Alon; Colin Defant; Noah Kravitz; Daniel G. Zhu | 2023-08-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020303 | GAX-AX_vertex_critical_edge_robust_fixed_k

Vertex-critical graphs far from edge-criticality | Open case of Erdős's problem for fixed small k

论文中定位：Open case of Erdős's problem for fixed small k；类型：Problem。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Anders Martinsson; Raphael Steiner | 2023-10-19

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020304 | GAX-AX_weightable_digraphs_np_characterization

When all directed cycles have length three | Informal Question (NP-characterization of weightable digraphs)

论文中定位：Informal Question (NP-characterization of weightable digraphs)；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Paul Seymour | 2025-02-09

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020305 | GAX-AX_widespread_multigraph_all

Induced subgraphs of graphs with large chromatic number. VI. Banana trees | Conjecture 1.8

论文中定位：Conjecture 1.8；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2019-08-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020306 | GAX-AX_widespread_multigraph_chi_2_subdivision_free

Induced subgraphs of graphs with large chromatic number. VI. Banana trees | Conjecture 1.10

论文中定位：Conjecture 1.10；类型：Conjecture。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Alex Scott; Paul Seymour | 2019-08-27

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020307 | GAX-AX_zombie_number_leaf_attachment_invariance

A note on deterministic zombies | Question 4.1

论文中定位：Question 4.1；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Valentin Bartier; Laurine Bénéteau; Marthe Bonamy; Hoang La; Jonathan Narboni | 2021-06-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

V3-020308 | GAX-AX_zombie_number_subdivision_increase

A note on deterministic zombies | Question 4.2

论文中定位：Question 4.2；类型：Question。本卷仅收录原文入口，不以自动抽取标记认证开放状态。

仅来源定位 | extraction_role_states | Valentin Bartier; Laurine Bénéteau; Marthe Bonamy; Hoang La; Jonathan Narboni | 2021-06-03

摘录，定义可能依赖原文 | 原始来源 | metadata only

C05 Epoch / OEIS 历史定位｜42 条

V3-020309 | EPOCH-A338238_infinitely_often_primorial_conjecture

A338238 | Minimum number of rotations for a second maximum cyclic autocorrelation of the first n terms of the characteristic function of primes.

历史提出者：Andres Cicuttin；提出日期：2020-10-17；元数据声明名：A338238_infinitely_often_primorial_conjecture。请核对 OEIS 当前内容与修订历史。

仅来源定位 | AI_summarized_historical_metadata | Andres Cicuttin | 2020-10-17

D 参数型开放问题实例：9,342 行

本附录的实例来自 ConjectureBench 对六个原始问题族的整理。记录给出具体参数和观察日的开放范围；数值事实不等同于一项有独立名称的猜想。因此，这 9,342 行没有计入封面的 20,360 条主目录。

D01 二元常权码 | 250 行

A(n,d,w) 是长度 n、重量 w、两两 Hamming 距离至少 d 的二进制码的最大大小。best_known 为已知构造大小，upper_bound 为来源给出的上界。

D04 覆盖设计 | 1,480 行

C(v,k,t) 是覆盖 v 元集全部 t 元子集所需 k 元块的最少数目。best_known 为已知覆盖所用块数，是上界；lower_bound 是来源宣称的下界。来源下界与另列的计算所得 Schönheim 界可能不同；条目据此将来源原称的 Schoenheim bound 转述为 source-reported lower bound，本卷没有重新证明较强下界。

原始问题族入口

V3P-009295 | ramsey-r-10-10

Two-colour Ramsey number R(10, 10)

colourings of K_797 avoiding both are known, so R(10, 10) >= 798, and the survey's best upper bound is 16064.

来源状态 open | 2026-07-23 | 来源

V3P-009296 | ramsey-r-3-10

Two-colour Ramsey number R(3, 10)

colourings of K_39 avoiding both are known, so R(3, 10) >= 40, and the survey's best upper bound is 41.

来源状态 open | 2026-07-23 | 来源

V3P-009297 | ramsey-r-3-11

Two-colour Ramsey number R(3, 11)

colourings of K_46 avoiding both are known, so R(3, 11) >= 47, and the survey's best upper bound is 50.

来源状态 open | 2026-07-23 | 来源

V3P-009298 | ramsey-r-3-12

Two-colour Ramsey number R(3, 12)

colourings of K_52 avoiding both are known, so R(3, 12) >= 53, and the survey's best upper bound is 59.

来源状态 open | 2026-07-23 | 来源

V3P-009299 | ramsey-r-3-14

Two-colour Ramsey number R(3, 14)

colourings of K_66 avoiding both are known, so R(3, 14) >= 67, and the survey's best upper bound is 77.

来源状态 open | 2026-07-23 | 来源

V3P-009300 | ramsey-r-3-15

Two-colour Ramsey number R(3, 15)

colourings of K_73 avoiding both are known, so R(3, 15) >= 74, and the survey's best upper bound is 87.

来源状态 open | 2026-07-23 | 来源

V3P-009301 | ramsey-r-4-10

Two-colour Ramsey number R(4, 10)

colourings of K_91 avoiding both are known, so R(4, 10) >= 92, and the survey's best upper bound is 135.

来源状态 open | 2026-07-23 | 来源

V3P-009302 | ramsey-r-4-11

Two-colour Ramsey number R(4, 11)

colourings of K_101 avoiding both are known, so R(4, 11) >= 102, and the survey's best upper bound is 170.

来源状态 open | 2026-07-23 | 来源

V3P-009303 | ramsey-r-4-12

Two-colour Ramsey number R(4, 12)

colourings of K_127 avoiding both are known, so R(4, 12) >= 128, and the survey's best upper bound is 210.

来源状态 open | 2026-07-23 | 来源

V3P-009304 | ramsey-r-4-6

Two-colour Ramsey number R(4, 6)

colourings of K_35 avoiding both are known, so R(4, 6) >= 36, and the survey's best upper bound is 40.

来源状态 open | 2026-07-23 | 来源

V3P-009305 | ramsey-r-4-7

Two-colour Ramsey number R(4, 7)

colourings of K_48 avoiding both are known, so R(4, 7) >= 49, and the survey's best upper bound is 58.

来源状态 open | 2026-07-23 | 来源

V3P-009306 | ramsey-r-4-8

Two-colour Ramsey number R(4, 8)

colourings of K_58 avoiding both are known, so R(4, 8) >= 59, and the survey's best upper bound is 79.

来源状态 open | 2026-07-23 | 来源

V3P-009307 | ramsey-r-4-9

Two-colour Ramsey number R(4, 9)

colourings of K_72 avoiding both are known, so R(4, 9) >= 73, and the survey's best upper bound is 105.

来源状态 open | 2026-07-23 | 来源

V3P-009308 | ramsey-r-5-10

Two-colour Ramsey number R(5, 10)

colourings of K_148 avoiding both are known, so R(5, 10) >= 149, and the survey's best upper bound is 381.

来源状态 open | 2026-07-23 | 来源

V3P-009309 | ramsey-r-5-11

Two-colour Ramsey number R(5, 11)

colourings of K_182 avoiding both are known, so R(5, 11) >= 183, and the survey's best upper bound is 511.

来源状态 open | 2026-07-23 | 来源

V3P-009310 | ramsey-r-5-12

Two-colour Ramsey number R(5, 12)

colourings of K_202 avoiding both are known, so R(5, 12) >= 203, and the survey's best upper bound is 672.

来源状态 open | 2026-07-23 | 来源

V3P-009311 | ramsey-r-5-13

Two-colour Ramsey number R(5, 13)

colourings of K_232 avoiding both are known, so R(5, 13) >= 233, and the survey's best upper bound is 860.

来源状态 open | 2026-07-23 | 来源

V3P-009312 | ramsey-r-5-14

Two-colour Ramsey number R(5, 14)

colourings of K_266 avoiding both are known, so R(5, 14) >= 267, and the survey's best upper bound is 1081.

来源状态 open | 2026-07-23 | 来源

V3P-009313 | ramsey-r-5-15

Two-colour Ramsey number R(5, 15)

colourings of K_274 avoiding both are known, so R(5, 15) >= 275, and the survey's best upper bound is 1341.

来源状态 open | 2026-07-23 | 来源

V3P-009314 | ramsey-r-5-5

Two-colour Ramsey number R(5, 5)

colourings of K_42 avoiding both are known, so R(5, 5) >= 43, and the survey's best upper bound is 46.

来源状态 open | 2026-07-23 | 来源

V3P-009315 | ramsey-r-5-6

Two-colour Ramsey number R(5, 6)

colourings of K_58 avoiding both are known, so R(5, 6) >= 59, and the survey's best upper bound is 85.

来源状态 open | 2026-07-23 | 来源

V3P-009316 | ramsey-r-5-7

Two-colour Ramsey number R(5, 7)

colourings of K_79 avoiding both are known, so R(5, 7) >= 80, and the survey's best upper bound is 133.

来源状态 open | 2026-07-23 | 来源

V3P-009317 | ramsey-r-5-8

Two-colour Ramsey number R(5, 8)

colourings of K_100 avoiding both are known, so R(5, 8) >= 101, and the survey's best upper bound is 193.

来源状态 open | 2026-07-23 | 来源

V3P-009318 | ramsey-r-5-9

Two-colour Ramsey number R(5, 9)

colourings of K_132 avoiding both are known, so R(5, 9) >= 133, and the survey's best upper bound is 282.

来源状态 open | 2026-07-23 | 来源

V3P-009319 | ramsey-r-6-10

Two-colour Ramsey number R(6, 10)

colourings of K_203 avoiding both are known, so R(6, 10) >= 204, and the survey's best upper bound is 944.

来源状态 open | 2026-07-23 | 来源

V3P-009320 | ramsey-r-6-11

Two-colour Ramsey number R(6, 11)

colourings of K_261 avoiding both are known, so R(6, 11) >= 262, and the survey's best upper bound is 1346.

来源状态 open | 2026-07-23 | 来源

V3P-009321 | ramsey-r-6-12

Two-colour Ramsey number R(6, 12)

colourings of K_293 avoiding both are known, so R(6, 12) >= 294, and the survey's best upper bound is 1855.

来源状态 open | 2026-07-23 | 来源

V3P-009322 | ramsey-r-6-13

Two-colour Ramsey number R(6, 13)

colourings of K_346 avoiding both are known, so R(6, 13) >= 347, and the survey's best upper bound is 2499.

来源状态 open | 2026-07-23 | 来源

V3P-009323 | ramsey-r-6-15

Two-colour Ramsey number R(6, 15)

colourings of K_400 avoiding both are known, so R(6, 15) >= 401, and the survey's best upper bound is 4305.

来源状态 open | 2026-07-23 | 来源

V3P-009324 | ramsey-r-6-6

Two-colour Ramsey number R(6, 6)

colourings of K_101 avoiding both are known, so R(6, 6) >= 102, and the survey's best upper bound is 160.

来源状态 open | 2026-07-23 | 来源

V3P-009325 | ramsey-r-6-7

Two-colour Ramsey number R(6, 7)

colourings of K_114 avoiding both are known, so R(6, 7) >= 115, and the survey's best upper bound is 270.

来源状态 open | 2026-07-23 | 来源

V3P-009326 | ramsey-r-6-8

Two-colour Ramsey number R(6, 8)

colourings of K_133 avoiding both are known, so R(6, 8) >= 134, and the survey's best upper bound is 423.

来源状态 open | 2026-07-23 | 来源

V3P-009327 | ramsey-r-6-9

Two-colour Ramsey number R(6, 9)

colourings of K_182 avoiding both are known, so R(6, 9) >= 183, and the survey's best upper bound is 651.

来源状态 open | 2026-07-23 | 来源

V3P-009328 | ramsey-r-7-10

Two-colour Ramsey number R(7, 10)

colourings of K_291 avoiding both are known, so R(7, 10) >= 292, and the survey's best upper bound is 2119.

来源状态 open | 2026-07-23 | 来源

V3P-009329 | ramsey-r-7-11

Two-colour Ramsey number R(7, 11)

colourings of K_404 avoiding both are known, so R(7, 11) >= 405, and the survey's best upper bound is 3197.

来源状态 open | 2026-07-23 | 来源

V3P-009330 | ramsey-r-7-12

Two-colour Ramsey number R(7, 12)

colourings of K_416 avoiding both are known, so R(7, 12) >= 417, and the survey's best upper bound is 4665.

来源状态 open | 2026-07-23 | 来源

V3P-009331 | ramsey-r-7-13

Two-colour Ramsey number R(7, 13)

colourings of K_510 avoiding both are known, so R(7, 13) >= 511, and the survey's best upper bound is 6653.

来源状态 open | 2026-07-23 | 来源

V3P-009332 | ramsey-r-7-7

Two-colour Ramsey number R(7, 7)

colourings of K_204 avoiding both are known, so R(7, 7) >= 205, and the survey's best upper bound is 492.

来源状态 open | 2026-07-23 | 来源

V3P-009333 | ramsey-r-7-8

Two-colour Ramsey number R(7, 8)

colourings of K_218 avoiding both are known, so R(7, 8) >= 219, and the survey's best upper bound is 832.

来源状态 open | 2026-07-23 | 来源

V3P-009334 | ramsey-r-7-9

Two-colour Ramsey number R(7, 9)

colourings of K_251 avoiding both are known, so R(7, 9) >= 252, and the survey's best upper bound is 1368.

来源状态 open | 2026-07-23 | 来源

V3P-009335 | ramsey-r-8-10

Two-colour Ramsey number R(8, 10)

colourings of K_342 avoiding both are known, so R(8, 10) >= 343, and the survey's best upper bound is 4402.

来源状态 open | 2026-07-23 | 来源

V3P-009336 | ramsey-r-8-11

Two-colour Ramsey number R(8, 11)

colourings of K_456 avoiding both are known, so R(8, 11) >= 457, and the survey's best upper bound is 7040.

来源状态 open | 2026-07-23 | 来源

V3P-009337 | ramsey-r-8-13

Two-colour Ramsey number R(8, 13)

colourings of K_816 avoiding both are known, so R(8, 13) >= 817, and the survey's best upper bound is 27485.

来源状态 open | 2026-07-23 | 来源

V3P-009338 | ramsey-r-8-15

Two-colour Ramsey number R(8, 15)

colourings of K_872 avoiding both are known, so R(8, 15) >= 873, and the survey's best upper bound is 63609.

来源状态 open | 2026-07-23 | 来源

V3P-009339 | ramsey-r-8-8

Two-colour Ramsey number R(8, 8)

colourings of K_281 avoiding both are known, so R(8, 8) >= 282, and the survey's best upper bound is 1518.

来源状态 open | 2026-07-23 | 来源

V3P-009340 | ramsey-r-8-9

Two-colour Ramsey number R(8, 9)

colourings of K_328 avoiding both are known, so R(8, 9) >= 329, and the survey's best upper bound is 2662.

来源状态 open | 2026-07-23 | 来源

V3P-009341 | ramsey-r-9-10

Two-colour Ramsey number R(9, 10)

colourings of K_580 avoiding both are known, so R(9, 10) >= 581, and the survey's best upper bound is 8675.

来源状态 open | 2026-07-23 | 来源

V3P-009342 | ramsey-r-9-9

Two-colour Ramsey number R(9, 9)

colourings of K_564 avoiding both are known, so R(9, 9) >= 565, and the survey's best upper bound is 4956.
