It is conjectured that a(n) >= A123690(n)-1, i.e., that it is always possible to find a path visiting all grid points covered by a circle, irrespective of the position of its center. - _Hugo Pfoertner_, Mar 02 2018 This conjecture is false. A counterexample is the configuration with 81 points and a diameter of 10, shown in the pdf with the illustrations for A123690. Not all of the four isolated points on the axes and the circumference of the enclosing circle, each with only one neighbor in the grid, can be part of a connecting Hamiltonian path. - _Hugo Pfoertner_, Jun 21 2026

V3-004137 | OEIS-A122226

Length of the longest possible self-avoiding path on the 2-dimensional triangular lattice such that the path fits into a circle of diameter n.

It is conjectured that the sequence is identical with A125852 for all n>1. That means that it is always possible to find an Hamiltonian cycle on the maximum possible number of lattice points that can be covered by circular disks of diameter >=2. For the given additional terms it was easily possible to construct such closed paths by hand, using the lattice subset found by the exhaustive search for A125852. See the examples at the end of the linked pdf file a122226.pdf that were all generated without using a program. - _Hugo Pfoertner_, Jan 12 2007

V3-004139 | OEIS-A122270

Numbers m such that the numerator of the Bernoulli number B(m) is divisible by a cube.

Conjecture: For all regular primes p > 3 and integers k > 0, the numerator of the Bernoulli number B(2*p^k) is divisible by p^k. Moreover, for all regular primes p > 3 and integers k > 0, m = 2*p^k is the smallest index such that the numerator of the Bernoulli number B(m) is divisible by p^k. Also, for all regular primes p > 3 and integers k > 0, all m such that the numerator of the Bernoulli number B(m) is divisible by p^k are of the form m = 2*s*p^k, where s > 0 is an integer.

a(0)=a(1)=0, a(2)=2; for n >= 3, a(n) = a(n-1) + 4*a(n-3).

Conjecture: count of even Markov numbers in generation n (with generations 0, 1 and 2 labeled as {5}, {13, 29} and {34, 194, 433, 169}. (Checked up to generation 20.) - _Wouter Meeussen_, Jan 16 2024 Wouter Meeussen's conjecture is true. Proof: label the Markov tree with Markov triples according to the scheme described at A368546. Mod 2, the triples are: row 0: (1,1,0); row 1: (1,1,1), (1,1,0); row 2: (1,0,1), (1,0,1), (1,1,1), (1,1,0); row 3: (1,1,0), (0,1,1), (1,1,0), (0,1,1), (1,0,1), (1,0,1), (1,1,1), (1,1,0); etc. Note that the Markov number labels of the tree (the center numbers of the triples) in rows 0 and 1 include no even numbers, while those in row 2 include two even numbers. Observing that the second triple in row 1 and the first four triples in row 3 are the same or the reverse of the root triple, and noting that every vertex in row 3 and beyond is in a subtree with one of these triples as root, the recurrence follows. - _William P. Orrick_, Mar 05 2024

V3-004184 | OEIS-A124197

Number of subsets S of {1,2,3,...,n}, including the empty subset, such that if x and y are in S with x<y and x+y even, then (x+y)/2 is also in S.

The sequence appeared in Problem B3 on the 2009 Putnam exam, which asked one to find all n for which the second difference equals 1. The second difference is the number of such subsets of {1,2,...,n+1} that contain both 1 and n+1. One such subset is {1,2,...,n+1}, and if n has an odd factor d>1 then the arithmetic progression {1,d+1,2d+1,...,n+1} works as well; hence the second difference is 1 iff n is a power of 2. [Note that the Putnam problem uses n+1 for our n.] This also means that the conjectural formula for the second difference is a lower bound. To prove the conjecture, note that consecutive elements of S alternate in parity (else S contains their average); thus if x,s,y are consecutive elements then x+y is even, so s=(x+y)/2, which means that S is a finite arithmetic progression with odd common difference. Since conversely any such arithmetic progression works, we are done. - _Noam D. Elkies_, Dec 05 2009

V3-004252 | OEIS-A126237

Length of row n in table A126014.

I conjecture that there are no gaps in the set of codeword lengths; that is, every integer that's between the minimum and maximum codeword lengths occurs as a codeword length. If so, then a(n) = A126236(n) - A126235(n). If, in addition, the conjectured formulas for the min and max lengths are correct, then a(n) = floor(log_2(n)) unless n has the form 3*2^k-1, in which case a(n) = floor(log_2(n)) - 1. This is true at least for n up to 1000.

V3-004253 | OEIS-A126241

Dropping time of n in the 3n+1 problem (or the Collatz problem). Let T(n):=n/2 if n is even, (3n+1)/2 otherwise (A014682). Let a(n) be the smallest integer k such that T^(k)(n)<n, where T^(k) is the k-th iterate, or infinity otherwise; a(n) is called the dropping time of n.

Terras defines a coefficient stopping time (definition 1.5) tau(n) = d which is the smallest d for which 3^u/2^d < 1 where u is the number of tripling steps among the first d steps starting from n. Clearly tau(n) <= a(n), and Terras conjectures (conjecture 2.9) that tau(n) = a(n) for n>=2. - _Olivier Rozier_, May 13 2024

V3-004295 | OEIS-A127208

Union of all n-step Lucas sequences, that is, all sequences s(1-n) = s(2-n) = ... = s(-1) = -1, s(0) = n and for k > 0, s(k) = s(k-1) + ... + s(k-n).

Noe and Post conjectured that the only positive terms that are common to any two distinct n-step Lucas sequences are the Mersenne numbers (A001348) that begin each sequence and 7 and 11 (in 2- and 3-step) and 5071 (in 3- and 4-step). The intersection of this sequence with the union of all the n-step Fibonacci sequences (A124168) appears to consist of 4, 21, 29, the Mersenne numbers 2^n-1 for all n and the infinite set of Eulerian numbers in A127232.

V3-004296 | OEIS-A127317

Numbers n such that (256^n + 1)/257 is prime.

We can even conjecture that ((Fj-1)^p + 1)/Fj is always squarefree for any odd prime p and for any Fermat number Fj with j >= 0. Note that this is not true if p is not restricted to be a prime, even if p and Fj are coprime, as shown by the following counterexample relative to the case j = 1, f1 = 5: 4^91 + 1 == 0 mod 1093^2. Remark that any such counterexample has to be a Wieferich prime (A001220), but not every Wieferich prime gives a counterexample, as shown by the second known Wieferich prime (3511), which cannot match here because it belongs to A072936.

V3-004314 | OEIS-A127823

Weighted Catalan numbers: number of combinatorial types of plane Morse links of order n.

a(n) has the same number of factors of 2 as does A000108(n) (Catalan numbers). "Given a sequence of integers b = (b_0,b_1,b_2,...) one gives a Dyck path P of length 2n the weight wt(P) = b_{h_1} b_{h_2} ... b_{h_n}, where h_i is the height of the i-th ascent of P. The corresponding weighted Catalan number is C_n^b = sum_P wt(P), where the sum is over all Dyck paths of length 2n. So in particular, the ordinary Catalan numbers C_n correspond to b_i = 1 for all i >= 0. Let xi(n) stand for the base two exponent of n, i.e., the largest power of 2 dividing n. We give a condition on b which implies that xi(C_n^b) = xi(C_n). In the special case b_i=(2i+1)^2, this settles a conjecture of Postnikov about the number of plane Morse links." - Alexander Postnikov, Bruce Sagan.

V3-004329 | OEIS-A128378

Partial sums of A128379.

Conjecture: Given the infinite set of sequences generated from using the partial sum operator on A000594, (i.e. A000012^k * A000594, k in succession = 1, 2, 3, ...), k = 23 and k = 24 are the only two sequences in the set with zeros. In A128379, k = 23: (1, -1, -24, 0, 276, 300, -1748, -4300,

...).

V3-004337 | OEIS-A128427

Last point where sum of n consecutive n-th powers does not exceed the next n-th power.

Denoting by x(n) the largest real root of (x-n)^n+...+(x-1)^n=x^N (so that by definition a(n)=floor(x(n))), it is conjectured ("Cyprian's Last Theorem") but not fully proved that x(n) is never an integer for n>3. A (very rapidly very good) asymptotic approximation to x(n) is 1.5 + n / ln2 + O(1/n), but this needs proof. This yields floor(1.5 + n / ln2) as an approximation to a(n).

V3-004348 | OEIS-A128818

Examples of integer-encoded mathematical structures in Max Tegmark's "The Mathematical Universe".

Abstract from "The Mathematical Universe" (see link below): "I explore physics implications of the External Reality Hypothesis (ERH) that there exists an external physical reality completely independent of us humans. I argue that with a sufficiently broad definition of mathematics, it implies the Mathematical Universe Hypothesis (MUH) that our physical world is an abstract mathematical structure. I discuss various implications of the ERH and MUH, ranging from standard physics topics like symmetries, irreducible representations, units, free parameters and initial conditions to broader issues like consciousness, parallel universes and Godel incompleteness. I hypothesize that only computable and decidable (in Godel's sense) structures exist, which alleviates the cosmological measure problem and help explain why our physical laws appear so simple. I also comment on the intimate relation between mathematical structures, computations, simulations and physical systems."

V3-004351 | OEIS-A128909

3D version of A005670. The problem is to dissect an n X n X n cube into smaller integer cubes, the gcd of whose sides is 1, using the smallest number of cubes. The gcd condition exclude dissecting a 6 X 6 X 6 cube into eight 3 X 3 X 3 cubes.

As far as I know, no term, (except trivial cases) has been proved optimal. Repeated dissection, as in the above example, shows that if the side is a composite number mn, a(mn) <= a(m) + a(n) - 1. It is an open problem to find a number mn for which a(mn) < a(m) + a(n) - 1. Dissecting a cube with side n into a cube with side n - 1 and several unit cubes gives a trivial bound: a(n) <= 3n^2 - 3n + 2. Dissecting a cube with side n = 2k + 1 into a cube with side k + 1, 7 with side k and several unit cubes gives another trivial bound: a(n) <= (9n^2 - 12n + 31) / 4.

An analog of Pascal's triangle: T(n,k) = A092143(n)/(A092143(n-k)*A092143(k)), 0 <= k <= n.

It appears that the T(n,k) are always integers. This would follow from the conjectured prime factorization given in the comments section of A092143.

V3-004364 | OEIS-A129453

An analog of Pascal's triangle based on A092287. T(n,k) = A092287(n)/(A092287(n-k)*A092287(k)), 0 <= k <= n.

It appears that the T(n,k) are always integers. This would follow from the conjectured prime factorization given in A092287. Calculation suggests that the binomial coefficients C(n,k) divide T(n,k) and indeed that T(n,k)/C(n,k) are perfect squares.

V3-004396 | OEIS-A130536

Prime numbers arising from A057856.

Conjecture: For all pairs of relative prime numbers (x, y) there exists at least one number n = 2^m and one prime number p such that p = x^n + y^n. This sequence shows one case of this conjecture where y = x + 1. The conjecture for arbitrary coprime positive integers x and y is false. Take x = 8 and y = 27. For every integer r >= 1, 8^r + 27^r = (2^r + 3^r)*(4^r - 6^r + 9^r), with both factors greater than 1. In particular, 8^(2^m) + 27^(2^m) is composite for every integer m >= 0. This does not refute the special case y = x + 1. See also A057856. - _Eiver Rodríguez_, Oct 01 2026

V3-004404 | OEIS-A130729

Fermat numbers of order 3 or F(n,3) = 2^(2^n) + 3.

This is equivalent to F(n)+2 or 2^(2^n)+ 1 + 2. Conjecture: If n is odd, 7 is a divisor of F(n,3). The conjecture is true: the order of 2 mod 7 is 3, and if n is odd then 2^n == 2 mod 3 so 2^(2^n) + 3 == 2^2 + 3 == 0 mod 7. - _Robert Israel_, Nov 20 2014

V3-004405 | OEIS-A130740

a(n) = 2^(4^n) + 5.

Numbers of the form 2^(4^n) + 5 are divisible by 7. We prove this by induction making use of the expansion (1) a^m - b^m = (a-b)(a^(m-1)+a^(m-2)b +...+ b^(m-1). For n = 1, we have 2^4 + 5 = 21 = 7*3. So the statement is true for n=1. Now assume the statement is true for some integer k and show that it is also true for k+1. Thus we have 2^(4^k) + 5 = 7h for some h. Let 2^(4^(k+1))+ 5 = h1. Now consider the difference h1 - 7h. If this is a multiple of 7 then so is h1. So we have 2^(4^(k+1))+ 5 - (2^(4^k) + 5)) = 16^(4^k)-2^(4^k). This is of the form (1) where n = 4^k, a = 16 and b = 2. So the difference, a^n-b^n is divisible by (a-b) = (16-2) = 14 = 7*2. This implies 2^(4^(k+1))+5 is divisible by 7. So we have assumed the statement was true for k and have shown it to be true for k+1. Therefore by the induction hypothesis, the statement is true for all n.

V3-004406 | OEIS-A130741

a(n) = 4^(4^n) + 3.

Numbers of the form 4^(4^n) + 3 are divisible by 7. We prove this by induction making use of the expansion (1) a^m - b^m = (a-b)(a^(m-1)+a^(m-2)b+...+b^(m-1). For n = 1, we have 4^4 + 3 = 259 = 7*37. So the statement is true for n=1. Now assume the statement is true for some integer k and show that it is also true for k+1. Thus we have 4^(4^k) + 3 = 7h for some h. Let 4^(4^(k+1))+ 3 = h1. Now consider the difference h1 - 7h. If this is a multiple of 7 then so is h1. So we have 4^(4^(k+1))+ 3 - (4^(4^k) + 3)) = 256^(4^k)-4^(4^k). This is of the form (1) where n = 4^k, a = 256 and b = 4. So the difference, a^n-b^n is divisible by (a-b) = (256-4) = 252 = 7*36. This implies 4^(4^(k+1))+3 is divisible by 7. So we have assumed the statement was true for k and have shown it to be true for k+1. Therefore by the induction hypothesis, the statement is true for all n.

V3-004445 | OEIS-A131657

For n >= 1, put A_n(z) = Sum_{j>=0} (n*j)!/(j!^n) * z^j and B_n(z) = Sum_{j>=0} (n*j)!/(j!^n) * z^j * (Sum_{k=1..j*n} (1/k)), and let b(n) be the largest integer for which exp(B_n(z)/(b(n)*A_n(z))) has integral coefficients. The sequence is b(n).

Krattenhaler and Rivoal (2007-2009) conjecture that a(n) = n!*Xi(n), where Xi(1) = 1, Xi(7) = 1/140, and Xi(n) = Product_{p <= n} p^min(2, v_p(H_n)) for n <> 1, 7, where v_p(r) is the p-adic valuation of rational r. (Here p indicates a prime and H_n is the n-th harmonic number.) - _Petros Hadjicostas_, May 24 2020 A formula, conditional on a widely believed conjecture, can be found in Theorem 3 with k = 1 in the article by Krattenhaler and Rivoal (2007-2009) cited in the references; see the remarks before Theorem 4 in that article.

V3-004454 | OEIS-A131971

a(0) = a(1) = a(2) = 1; a(n) = (a(n-1) + a(n-2) + a(n-3)) mod n.

Tribonacci (A000213) analog of A096535. The analogous 3 _Klaus Brockhaus_ conjectures are applicable: (1) All numbers appear infinitely often, i.e., for every number k >= 0 and every frequency f > 0 there is an index i such that a(i) = k is the f-th occurrence of k in the sequence. (2) a(j) = a(j-1) + a(j-2) + a(j-3) and a(j) = a(j-1) + a(j-2) + a(j-3) - j occur approximately equally often, i.e., lim_{n -> infinity} x_n / y_n = 1, where x_n is the number of j <= n such that a(j) = a(j-1) + a(j-2) + a(j-3) and y_n is the number of j <= n such that a(j) = a(j-1) + a(j-2) + a(j-3) - j (cf. A122276). (3) There are sections a(g+1), ..., a(g+k) of arbitrary length k such that a(g+h) = a(g+h-1) + a(g+h-2) + a(g+h-3) for h = 1,...,k, i.e., the sequence is nondecreasing in these sections (cf. A122277, A122278, A122279).

V3-004457 | OEIS-A132075

A conjectured permutation of the positive integers such that for every n, a(n) is the largest number among a(1), a(2), ..., a(n) that when added to a(n+1) gives a prime.

A conjectured permutation of the positive integers such that for every n, a(n) is the largest number among a(1), a(2), ..., a(n) that when added to a(n+1) gives a prime. It is not until the 26th truncated row - [1, 2, 3, 4, 7, 6] - that the initial list is extended at all. It is unclear whether this process can be continued indefinitely, although I have verified by computer that it generates a sequence of at least 2000 terms. Conjecturally: (1) the sequence is infinite, (2) it is the unique sequence containing infinitely many complete rows of table A088643, and (3) for every n > 0 there exists N > 0 such that the first n terms of this sequence are contained in every row of table A088643 from the N-th onwards.

V3-004461 | OEIS-A132163

Triangle read by rows. For row n, start with 1 but from the second term onwards always choose the largest positive integer between 1 and n inclusive that i) has not already appeared in the row ii) gives a prime when added to the previous term. Stop if no such integer can be found.

The following statements are conjectural: 1) The n-th row is always a permutation of 1,...,n. 2) For the even rows, the last term is one less than a prime (so the row gives a solution to the prime circle problem - see A051252). 3) There exists a (unique) sequence b(2), b(3),... with the property that for every n > 1 there is a positive integer N such that every even row of the triangle from the 2N-th onwards ends b(n), ..., b(3), b(2) and every odd row from the (2N - 1)-th onwards ends b(n)+(-1)^n, ..., b(3)-1, b(2)+1. (If the sequence b(n) exists it is probably A132075 without the initial term 1.)

V3-004476 | OEIS-A133154

a(n) is the smallest m<=p-1 such that p-1 is the only value of j in 1<=j<=2p for which m^j+j==0 (mod p), where p is the n-th prime.

Andrew Granville, based on submitter's analysis of the data in A131685, made the following conjecture: "For some n with 1<=n<=p-1, there does not exist a value of j, with 1 <= j <= 2p, other than j=p-1, for which n^j+j == 0 (mod p)." Max Alekseyev's calculations confirm that the conjecture is true for the primes between 5 and 10^5. The sequence consists of the first such "n" (referred to as "m" in this sequence's definition) for each prime. a(n)=0 means that there is no corresponding m; this occurs at n=1 (p=2), n=2 (p=3), and n=3 (p=5), and at no other primes p<10^5.

V3-004485 | OEIS-A133297

a(n) = n! * Sum_{k=1..n} (-1)^(k + 1) * n^(n - k - 1)/(n - k)!.

Conjecture: a(n) = (n-1)!*(Sum_{k >= 0} (-1)^k * n^(n+k)/(n+k)! - (-1/e)^n) for n >= 1. Cf. A000435. - _Peter Bala_, Jul 23 2021 This conjecture is true. Let "gamma" be the lower incomplete gamma function: gamma(n, x) = (n-1)! (1 - exp(-x)*Sum_{k = 0..n-1} x^k/k!), then we can get the upper incomplete gamma function Gamma(n, x) = gamma(n, oo) - gamma(n, x). By inserting according the formula below, we will obtain the formula from Peter Bala.

V3-004497 | OEIS-A133575

Table, read by rows, giving the number of vertices possible in 2 X n nondegenerate classical transportation polytopes.

This paper discusses properties of the graphs of 2-way and 3-way transportation polytopes, in particular, their possible numbers of vertices and their diameters. Our main results include a quadratic bound on the diameter of axial 3-way transportation polytopes and a catalog of non-degenerate transportation polytopes of small sizes. The catalog disproves five conjectures about these polyhedra stated in the monograph by Yemelichev et al. (1984). It also allowed us to discover some new results. For example, we prove that the number of vertices of an m X n transportation polytope is a multiple of the greatest common divisor of m and n.

V3-004502 | OEIS-A133697

a(n) = smallest number k such that P(k)/P(k+1) > P(k+1)/P(k+2) > ... > P(k+n+1)/P(k+n+2), where P(k) = k-th prime = A000040(k).

If 113 is, as conjectured, the last term of A124129, then P(a(n)) = A158939(n+2). Proof: Let x and y be the prime gaps following the prime p = P(j) > 113, so that P(j+1) = P(j) + x and P(j+2) = P(j) + x + y. The inequality P(j)/P(j+1) > P(j+1)/P(j+2) can be written as p/(p+x) > (p+x)/(p+x+y), which simplifies to y > x+x^2/p. By assumption, x^2 < p, so this holds if and only if y > x. So the condition P(j)/P(j+1) > P(j+1)/P(j+2) is equivalent to increasing prime gaps, P(j+2) - P(j+1) > P(j+1) - P(j). (In fact, since all prime gaps except the first are even, it is enough to assume the weaker conjecture that 7 is the only prime P(j) such that (P(j+1)-P(j))^2 >= 2*P(j).) - _Pontus von Brömssen_, Nov 19 2021

V3-004589 | OEIS-A136191

Primes p such that 2p-3 and 2p+3 are both prime (A092110), with last decimal being 3.

Theorem: If in the triple (2n-3,n,2n+3) all numbers are primes then n=5 or the decimal representation of n ends in 3 or 7. Proof: Consider Q=(2n-3)n(2n+3), by hypothesis factorized into primes. If n is prime, n=10k+r with r=1,3,7 or 9. We want to exclude r=1 and r=9. Case n=10k+1. Then Q=5(-1+6k+240k^2+800k^3) and 5 is a factor; thus 2n-3=5 or n=5 or 2n+1=5 : this means n=4 (not prime); or n=5 (included); or n=2 (impossible, because 2n-3=1). Case n=10k+9. Then Q=5(567+1926k+2160k^2+800k^3) and 5 is a factor; the arguments, for the previous case, also hold.

V3-004628 | OEIS-A137998

Least k such that floor(16^n / 10^k) = 1, 2, 4 or 8 (mod 10), or zero if no such k exists.

This is related to A071071, i.e., the conjecture by J. Shallit that {1,2,4,8,65536} is a minimal set for powers of 2 written in base 10. This amounts to saying that any power of 2 contains either a digit among {1,2,4,8}, or 65536 as subword (obtained by deleting zero or more digits of the number). The present sequence gives the position of the first digit (starting with units) of these powers which is among {1,2,4,8}. It appears as if 16^4=65536 is the only power of 2 which does not contain any of these four digits. This would imply the conjecture (and be an even stronger statement).

V3-004632 | OEIS-A138123

Antidiagonal sums of a triangle of coefficients of recurrences of the Fibonacci sequence.

Conjecture: The Fibonacci sequence F obeys all the recurrences: A000045(n)=F(n)= L(p)*F(n-p)-(-1)^p*F(n-2p), any p>0, L=A000204. [Proof: conjecture is equivalent to the existence of a g.f. of F with denominator 1-L(p)x^p+(-1)^p*x^(2p). Since 1-x-x^2 is known to be a denominator of such a g.f. of A000045, the conjecture is that 1-L(p)*x^p+(-1)^p*x^(2p) can be reduced to 1-x-x^2. One finds: {1-L(p)*x^p+(-1)^p*x^(2p)}/(1-x-x^2) = sum{n=0..p-1}F(n+1)x^n-sum{n=0..p-2} (-1)^(n+p)F(n+1)x^(2p-n-2) is a polynomial with integer coefficients, which is proved by multiplication with 1-x-x^2 and via F(n)+F(n+1)=F(n+2) and L(n)=F(n-1)+F(n+1). - _R. J. Mathar_, Jul 10 2008]. Conjecture: The Lucas sequence L also obeys all the recurrences: L(n)= L(p)*L(n-p)-(-1)^p*L(n-2p), any p>0, L=A000204. Conjectures from _Chai Wah Wu_, Apr 15 2024: (Start)

V3-004634 | OEIS-A138159

Triangle read by rows: T(n,k) is the number of permutations of [n] having k occurrences of the pattern 321 (n>=1, 0<=k<=n(n-1)(n-2)/6).

The number of 321-patterns of a given permutation p of [n] is given by Sum(L[i]R[i],i=1..n), where L (R) is the left (right) inversion vector of p. L and R are related by R[i]+i=p[i]+L[i] (the given Maple program makes use of this approach). References contain formulas and generating functions for the first few columns (some are only conjectured).

V3-004669 | OEIS-A140100

Start with Y(0)=0, X(1)=1, Y(1)=2. For n > 1, choose least positive integers Y(n) > X(n) such that neither Y(n) nor X(n) appear in {Y(k), 1 <= k < n} or {X(k), 1 <= k < n} and such that Y(n) - X(n) does not appear in {Y(k) - X(k), 1 <= k < n} or {Y(k) + X(k), 1 <= k < n}; sequence gives X(n) (for Y(n) see A140101).

Conjecture: A140100(n) - A140098(n) = A276404(n) is always 0 or 1; see A276406 for the positions where a difference of 1 occurs. The sequence is "tribonacci-synchronized"; this means there is a finite automaton recognizing the tribonacci representation of (n,a(n)) input in parallel, where a shorter input is padded with leading zeros. This finite automaton has 22 states and was verified with Walnut. In particular this finite automaton and a similar one for A140101 was used to verify that (conjecture of J. Cassaigne) either a(b(n)) = a(n)+b(n) or b(a(n)) = a(n)+b(n) for all n>=1, where b(n) = A140101(n). - _Jeffrey Shallit_, Oct 04 2022 Conjecture: the limit of X(n)/n = 1+1/t and limit of Y(n)/n = 1+t where the limit of Y(n)/X(n) = t = tribonacci constant (A058265), and thus the limit of (Y(n) + X(n))/(Y(n) - X(n)) = t^2 and the limit of (Y(n)^2 + X(n)^2)/(Y(n)^2 - X(n)^2) = t. It is conjectured in A305392 that the first differences of (X(n)) as a word are given by 212121 delta(x), where x is the tribonacci word x = A092782, and delta is the morphism This conjecture implies the frequency conjectures above: let N(i,n) be the number of letters i in x(1)x(2)...x(n). Then simple counting gives

V3-004670 | OEIS-A140101

Start with Y(0)=0, X(1)=1, Y(1)=2. For n > 1, choose least positive integers Y(n) > X(n) such that neither Y(n) nor X(n) appear in {Y(k), 1 <= k < n} or {X(k), 1 <= k < n} and such that Y(n)-X(n) does not appear in {Y(k)-X(k), 1 <= k < n} or {Y(k)+X(k), 1 <= k < n}; sequence gives Y(n) (for X(n) see A140100).

Conjecture: a(n) = A003144(n) + n. (This is from my notebook Lattices 115 page 20 from Oct 25 2016. It is now a theorem - see the Dekking et al. paper.) - _N. J. A. Sloane_, Jul 22 2019 The sequence is "tribonacci-synchronized"; this means there is a finite automaton recognizing the tribonacci representation of (n,a(n)) input in parallel, where a shorter input is padded with leading zeros. This finite automaton has 23 states and was verified with Walnut. In particular this finite automaton and a similar one for A140101 was used to verify that (conjecture of J. Cassaigne) either a(b(n)) = a(n)+b(n) or b(a(n)) = a(n)+b(n) for all n>=1, where b(n) = A140100(n). - _Jeffrey Shallit_, Oct 04 2022 CONJECTURE: the limit of a(n)/n = 1+t and limit of X(n)/n = 1+1/t so that limit of a(n)/X(n) = t = tribonacci constant (A058265), and thus the limit of [a(n) + X(n)]/[a(n) - X(n)] = t^2 and the limit of [a(n)^2 + X(n)^2]/[a(n)^2 - X(n)^2] = t. Conjectured recursion: Take first differences: 3, 3, 3, 2, 3, 3, 3, 3, 3, 2, ... (appears to consist of only 3's and 2's); list the run lengths: 3, 1, 6, 1, 5, 1, 6, 1, 3, 1, 6, 1, 5, 1, 6, 1, ... (it appears that every second term is 1 and the other terms are 3, 5, and 6); and bisect, getting 3, 6, 5, 6, 3, 6, 5, 6, 6, 5, 6, 3, 6, ... This is (although I do not have a proof) the recursively defined A275925. Thanks to _Alois P. Heinz_ for providing enough terms of A273059 to enable a (morally) convincing check of this conjecture. - _N. J. A. Sloane_, Aug 30 2016 This conjecture can be reformulated as follows (cf. A140100). This conjecture implies the frequency conjecture above: let N(i,n) be the number of letters i in a(1)a(2)...a(n). Then simple counting gives

V3-004672 | OEIS-A140110

Numbers n such that for all divisors of n, ratios of 2 consecutive divisors of n will always reduce to lowest terms as a ratio of consecutive integers.

Proof of John W. Layman's conjecture that every term after the second is a multiple of 4 or 6. The first divisor of any number is always 1. Because the only divisor of 1 is 1, the second divisor of any member of this sequence greater than 1 is 2. Because the divisors of 2 are 1 and 2, the third divisor of any term of this sequence is always either 3 (proving it is a multiple of 6 because 6 is the LCM of 2 and 3) or 4. Therefore every term greater than 2 in this sequence is a multiple of at least one of 4 and 6. - _J. Lowell_, Jul 07 2008 It appears that consecutive elements of this sequence (for n>1) are consecutive solutions of the equation n = 1 + Sum_{k=1..tau(n)-1} gcd(d_k(n), d_(k+1)(n)), where d_k(n) denotes the k-th smallest divisor. The conjecture was checked for 10^8 consecutive integers. - _Lechoslaw Ratajczak_, Jan 09 2017

V3-004673 | OEIS-A140124

a(n) = degree in N of the number of orbits under S_N of the set of n-tuples of partitions of {1,...,N} into n subsets.

This formula and its first two values are given in Bergman, p. 18. Abstract: Erdos and Szekeres showed in 1978 that for any four positive integers satisfying m_1+m_2 = n_1+n_2, the two binomial coefficients (m_1+m_2)!/m_1! m_2! and (n_1+n_2)!/n_1! n_2! have a common divisor >1. The analogous statement for families of k k-nomial coefficients (k>1) was conjectured in 1997 by David Wasserman. Erdos and Szekeres remark that if m_1, m_2, n_1, n_2 as above are all >1, there is probably a lower bound on the common divisor in question which goes to infinity as a function of m_1+m_2. Such a bound is here obtained. Results are proved that narrow the class of possible counterexamples to Wasserman's conjecture. On the other hand, several plausible generalizations of that conjecture are shown to be false.

V3-004682 | OEIS-A140454

Number of primes p less than 10^n such that p^2-2 is prime.

Korevaar gives these values in Table 1, p. 18, attributing the calculation to Fokko van de Bult. Abstract: For any positive integer r, let pi_{2r}(x) denote the number of prime pairs (p, p+2r) with p not exceeding (large) x. According to the prime-pair conjecture of Hardy and Littlewood, pi_{2r}(x) should be asymptotic to 2C_{2r}li_2(x) with an explicit positive constant C_{2r}. A heuristic argument indicates that the remainder e_{2r}(x) in this approximation cannot be of lower order than x^beta, where beta is the supremum of the real parts of zeta's zeros. The argument also suggests an approximation for pi_{2r}(x) similar to one of Riemann for pi(x).

V3-004710 | OEIS-A141387

Triangle read by rows: T(n,m) = n + 2*m*(n - m) (0 <= m <= n).

Construct the infinite-dimensional matrix representation of angular momentum operators (J_1,J_2,J_3) in Jordan-Schwinger form (cf. Harter, Klee, Schwinger). The triangle terms T(n,k)=T(2j,j+m) satisfy:(1/4)T(2j,j+m) = <j,m|J_1^2|j,m> = <j,m|J_2^2|j,m>. Matrices for J_1^2 and J_2^2 are sparse. These diagonal equalities and the off-diagonal equalities of A268759 determine the only nonzero entries. Comments on A268759 provide a conjecture for the clear interpretation of these numbers in the context of binomial coefficients and other geometrical sequences. - _Bradley Klee_, Feb 20 2016

V3-004737 | OEIS-A143027

Sturdy prime numbers: p such that in binary notation k*p has at least as many 1-bits as p for all k > 0.

Max Alekseyev reports that 6700417, 13264529, 20394401, and 97685839 are not sturdy because each number divides a number having fewer 1-bits: 6700417 divides 2^32 + 1, 13264529 divides 331613225, 20394401 divides 1611157679, and 97685839 divides 18014398643699713. He conjectures that 616318177 is the next term.

V3-004739 | OEIS-A143105

Let g_0(x,y)=x, g_1(x,y)=x^3+3xy and g_{n+2}(x,y) = (x^2+2y)g_{n+1}(x+y)-y^2g_n(x,y). The entries of the sequence are those odd d for which g_d(x,y) and cx^jy^kg_m(x,y) have at least two terms in common (same coefficients) for some c > 0 and integers j,k and such that g_d(x,y) + cx^jy^k(1+y^m - g_m(x,y)) has all positive coefficients.

It is unknown if this sequence is infinite (conjectured to be so). Furthermore A143106 is definitely a subsequence of this sequence, but it is unknown if the two are in fact equal.

V3-004740 | OEIS-A143106

Odd degrees for which (up to swapping of variables) there exists a unique polynomial p(x,y), such that p(x,y)=1 when x+y=1, with positive coefficients and such that the number of terms is minimal (equal to (d+3)/2). There always exists a group invariant polynomial (see any of the references), but for many degrees, other such extremal polynomials exist.

This sequence is a subsequence of A143105. It is unknown if this is the same sequence, nor if this sequence is infinite (conjectured to be such). It is not currently computationally feasible to find out if 21 belongs in this sequence or not.

V3-004741 | OEIS-A143109

Let H(2,d) be the space of polynomials p(x,y) of two variables with nonnegative coefficients such that p(x,y)=1 whenever x + y = 1. a(n) is the number of different polynomials in H(2,d) with exactly n distinct monomials and of maximum degree minus two, i.e., of degree 2n-5.

It is unknown but conjectured that this is a sequence of finite numbers. Note that if we went one degree lower and look at polynomials of degree 2n-6, then there are infinitely many if any exist in H(2,d).

V3-004748 | OEIS-A143510

Numbers m such that the equation phi(x) = m has even but no odd solutions.

In the unlikely event that Carmichael's conjecture is proved false, the counterexamples will be in this sequence. The number a(1) = 16842752 = 257*2^16 is mentioned in problem E3361. If there are only five Fermat primes, then 2^k is in this sequence for all k>31. It appears that for every product d of Fermat primes (A143512), the number 2^k * d is in this sequence for some k. The link to "Numbers Like 16842752" lists examples for various d. Conjecture: if the least solution to phi(x) = m is even, then m is in this sequence. - _Jianing Song_, Nov 07 2022 The conjecture holds for the first 26 such numbers, see A387221. - _Jud McCranie_, Dec 17 2025

V3-004763 | OEIS-A143898

Number of primes between n^K and (n+1)^K, where K = log(1151)/log(95).

This value of K is conjectured to be the least possible such that there is at least one prime in the range n^K to (n+1)^K for n > 0. This value of K was found using exact interval arithmetic. For each n <= 110 and for each prime p in the range n to n^1.7, we computed an interval k(n,p) such that p is between n^k(n,p) and (n+1)^k(n,p). The intersection of all these intervals produces a list of intervals. The least value in those intervals is K, which is log(1151)/log(95). We computed 10^5 terms of this sequence to give us confidence that a(n) > 0 for all n. 1151 counts as a qualifying prime towards both a(94)=1 and a(95)=3, in accordance with use of closed ranges. If prime p were counted only when n^K < p <= (n+1)^K, then term 95 would be 2. If prime p were counted only when n^K <= p < (n+1)^K, then term 94 would be 0. The conjecture in the author's comment implies K is the greatest real value such that for all e <= K there exists n > 0 with no prime p satisfying n^e <= p < (n+1)^e. - _Peter Munn_, Mar 02 2017 The author's description of the calculation of K implies that K is not an isolated qualifying value; equivalently that K is also the least real value for which there is a positive epsilon such that for all exponent e, K <= e <= K+epsilon and integer n > 0 there is a prime p satisfying n^e <= p <= (n+1)^e. This is a necessary precondition for my Mar 02 2017 deduction from the author's conjecture. - _Peter Munn_, Aug 21 2019

V3-004765 | OEIS-A143935

Number of primes between n^K and (n+1)^K, inclusive, where K=log(127)/log(16).

This value of K is conjectured to be the least possible such that there is at least one prime in the range n^k and (n+1)^k for all n>0 and k>=K. This value of K was found using exact interval arithmetic. For each n <= 300 and for each prime p in the range n to n^2, we computed an interval k(n,p) such that p is between n^k(n,p) and (n+1)^k(n,p). The intersection of all these intervals produces a list of 29 intervals. The last interval appears to be semi-infinite beginning with K, which is log(127)/log(16). See A143898 for the smallest number in the first interval.

V3-004777 | OEIS-A144326

Prime numbers that cannot be Mersenne prime exponents, by conjecture of A144325.

Prime numbers that cannot be Mersenne prime exponents, by conjecture of A144325. Conjecture: 191, 1217, 1559 and 1901 are not in fact members of this sequence, noting that they are (4, 19) k-figurate numbers; 19 is a member of A138694. Determining whether a Mersenne prime exponent one greater than a (4, 19) k-figurate number exists is sufficient to determine whether these primes are members.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-004787 | OEIS-A144621

a(0) = a(1) = 1 and a(n+2) = a(n+1) * (3*a(n+1) - 2*a(n)^2), n>=0.

Conjecture: a(n+1) = determinant of 2^n x 2^n matrix M where M(i,j) = 1 + exponent of 2 in the factorization of i+j-1 = A001511(i+j-1), i,j>0, n>2. - _Ralf Stephan_, Sep 27 2013 The conjecture above is true. The matrix M(n+1) is equivalent via an even number of row and column interchanges to the matrix T(n+1) defined by: T(0)=1; T(n) = I(2) X T(n-1) + 1(2^n)(1(2^n))^T, where X is the Kronecker product, I(2) is the 2 X 2 identity matrix, 1(k) is a column vector of k 1s and T is matrix transpose. All rows of this matrix have the same sum (n+1) + sum_{j=1..n}j*2^(n-j) = 2^(n+1)-1 hence this is the eigenvalue of the eigenvector 1(2^n). Now det(T(n)) = (det(T(n-1)))(det(T(n-1)+2*1(2^(n-1))(1(2^(n-1)))^T)) = (det(T(n-1))^2)(1+2*(1(2^(n-1)))^T (T(n-1))^{-1} 1(2^(n-1))) = (det(T(n-1))^2)((2-2^(-n))/(1-2^(-n))). Let v(n)=(2-2^(-(n+1)))/(1-2^(-(n+1))) and notice that v(n) = 3-2/(v(n-1)). Then det(T(n)) = (det(T(n-1))^2)(3-2/v(n-1)) = (det(T(n-1))^2)(3-2(det(T(n-2))^2)/(v(n-1)det(T(n-2))^2))= det(T(n-1))(3det(T(n-1))-2det(T(n-2))^2). In the closed-form product formula we see the eigenvalues of T(n). The matrix T(n) is the matrix of times of most recent common ancestors for a 2^n tips, fully balanced binary phylogenetic tree with unit branch lengths. - _Krzysztof Bartoszek_, Mar 23 2015

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-004812 | OEIS-A145236

a(n) is the least positive integer such that if p_n is the n-th prime then (ceiling(sqrt(a(n)*p_n)))^2 - a(n)*p_n is a perfect square.

Conjectures: 1) for n >= 2, the sequence does not decrease; 2) for n > 1, a(n) is odd; 3) a(n) can be equal to a(n+1) only for twins: p_(n+1) - p_n = 2 (although there also exist twins

for which a(n) < a(n+1)). All these conjectures are proved using the formula a(n) = p_n - 2*floor(sqrt(2p_n)) + 2, n > 1. See also A145701 and A145714. - _Vladimir Shevelev_, Oct 18 2008

V3-004813 | OEIS-A145300

a(n) is the maximal prime such that if p_n is the n-th prime then ceiling(sqrt(a(n)*p_n))^2 - a(n)*p_n is a perfect square.

Or a(n) is the maximal prime q_n > p_n such that sqrt(q_n)-sqrt(p_n) < sqrt(2) [or (p_n+q_n)/2 < sqrt(p_n*q_n)+1]. I conjecture that lim_{n->infinity} (sqrt(q_n) - sqrt(p_n)) = sqrt(2). Note that in the considered case this conjecture is equivalent to the following: lim_{n->infinity} fract(sqrt(p_n*q_n)) = 0, where fract(x) denotes the fractional part of x. - _Vladimir Shevelev_, Oct 09 2008

V3-004822 | OEIS-A145679

Lower limit of backward value of 2^n and n!.

The sum of constants in this sequence and A023415 is conjectured to be 11 exactly. The equality of the backward sequences for n! omitting the trailing sequence zeros and 2^n holds under the conjecture that for each k and each r not divisible by 5 there are infinitely many n for which n! without trailing zeros = r mod 5^k. Actually this conjecture is true because for m > 0 g(k)^m = ((5^k)(5^(4m) - 1)/(5^4 - 1))! without leading zeros mod 5^k, and g(k) is a generator of the multiplicative group mod 5^k for k=3 mod 4 by induction using g(k+4) = g(k) mod 5^k. The above conjecture about the sum of constants in this sequence and A023415 can be proved using the recursion formulas for the sequences.

V3-004852 | OEIS-A146961

Numbers k = p*q*r, with odd primes p < q < r, such that Sister Beiter's cyclotomic coefficient conjecture is false.

Numbers k = p*q*r, with odd primes p < q < r, such that Sister Beiter's cyclotomic coefficient conjecture is false. In 1968, Sister Beiter conjectured that for k = p*q*r, with odd primes p < q < r, the maximum coefficient (in absolute value) of the cyclotomic polynomial Phi(k,x) is <= (p+1)/2. Up to 10^6, all counterexamples have p > 7. Gallot and Moree prove the conjecture is false for p > 7.

V3-004869 | OEIS-A152009

(L)-sieve transform of {1,4,7,10,...,3n-2,...} (A016777).

The (L)-sieve transform is quite different from the transform introduced by _N. J. A. Sloane_ in A099361 and used by T. D. Noe in A100424 - A100426 and seems to lead to more interesting results and relationships among sequences. An interesting property of the (L)-sieve transform is that the (L)-sieve transform of the sequence {1,3,6,10,...,n(n+1)/2,...} of triangular numbers is again the triangular numbers. Another (conjectured) connection with the triangular numbers is given in the following. Conjecture. Let x(0) be a random sequence of positive integers and, for n>0, let x(n)=S[x(n-1)], where S is the (L)-sieve transform. Then the limit of {x(n)} as n goes to infinity is the sequence of triangular numbers {1,3,6,10,...,n(n+1)/2,...}. Illustration of the conjecture:

V3-004879 | OEIS-A152396

Let f(M,k) denote the decimal concatenation of k numbers starting with M: M | M-1 | M-2 | ... | M-k+1, k > 1. Then a(n) is the smallest M such that for all m in {1,..,n} an m-th prime occurs as f(M,k) for the smallest possible k, order prioritized m = 1 through n.

The sequence of k values is 2, 4, 8, 10, 14, 20, 28, 32, 34, 40, 50, etc. a(n) is necessarily congruent to 10 modulo 30 starting with n=4 (and is coincidentally so for n=2 and 3). Each successive unknown term's existence is only conjectural, but is supported by standard heuristics. The values in the lead sentence come through considerations modulo the smallest primes. Concatenation of 22 numbers is ruled out by consideration modulo 11 in concert with the prior need for the stem to be 10 mod 30: A prime concatenation of 22 values necessarily involves passage from one length number to another, with a power of 10 not leading. Beginning with a(11), however, with each time a multiple of 22 for the number of concatenated values is passed there is a measure of uncertainty. Theoretically, it seems a(11) could include for largest prime a concatenation of 44 (rather than 50) values, but with these primes very sparse it is a near certainty heuristically that this is not so. Mathematically, a conjectured a(11) would have a higher bar for strict proof than a(n) for n < 11, and the same holds repeatedly for even less accessible terms.

V3-004881 | OEIS-A152461

Primes p such that there does not exist any positive integer k and prime q with p > q and 3^k = p + 2q or 3^k = q + 2p.

If there exists a sequence N_k = 3^n_k such that N_k has O((N_k)^v), v < 1/2, representations of the considered form, then removing the maximal primes in every such representation, we obtain an analog B of A152461 with the counting function Z(x) = pi(x) - O(x^v). Replacing in B the first N terms with N consecutive primes (with arbitrarily large N), we obtain a sequence which essentially is indistinguishable from the sequence of all primes with the help of the approximation of pi(x) by li(x), since, according to the well-known Littlewood result, the remainder term in the theorem of primes cannot be less than sqrt(x)logloglog(x)/log(x). But for this sequence we have infinitely many odd numbers which are not expressible by sum p + 2q with p, q primes. Thus in this case the Lemoine-Levy conjecture is essentially unprovable. Nevertheless, we conjecture that there does not exist a considered abnormal case of sequence (N_k).

V3-004882 | OEIS-A152466

a(1) = 252, a(n) is a(n-1) multiplied by the smallest prime factor of a(n-1)+1.

Conjecture: this sequence contains no terms k where k+1 is prime. (All similar sequences that start with numbers less than 252 are known to contain terms k where k+1 is prime.) The above conjecture has now been disproved: adding 1 to the 39th term of this sequence gives a prime number. - _Andrea Concaro_, Dec 31 2022 Conjecture: a(n) = A238642(a(n-1)). - _J. Lowell_, Mar 25 2014 [This conjecture fails at n=40; see the above comment from _Andrea Concaro_. - _Jon E. Schoenfield_, Jan 15 2023]

Floor of harmonic energy of the conjectural minimal-energy configurations of n points on the unit sphere in R^4, under the harmonic potential function.

Floor of harmonic energy of the conjectural minimal-energy configurations of n points on the unit sphere in R^4, under the harmonic potential function. Floor of the right-hand column of the subtable for k=4 given by Ballinger et al., in the table of data related to their paper. This table shows the conjectural minimal-energy configurations of n points on the unit sphere in R^k (for k from 2 to 64), under the harmonic potential function: the potential energy between two points at distance r is 1/r^(k-2). In each entry in the table, the column for n links to coordinates for the configuration (given as a plain text file in which each line lists the coordinates for one point).

V3-004925 | OEIS-A154258

Number of triples <p,s,t> such that p+F_s+(F_t)^2=n, where p is an odd prime, s and t are greater than one and the Fibonacci number F_s or F_t is odd.

Zhi-Wei Sun conjectured that a(n)>0 for all n=5,6,... (i.e., any integer n>4 can be written as the sum of an odd prime, a positive Fibonacci number and a square of a positive Fibonacci number, with one of the two Fibonacci numbers odd). He has verified this for n up to 3*10^7. _Zhi-Wei Sun_ has offered a monetary reward for settling this conjecture.

V3-004930 | OEIS-A154364

Number of ways to express n as the sum of an odd prime, a positive Pell number and a companion Pell number.

This is inspired by the sequence A154290 and related conjectures of Sun. On Jan 08 2009, Zhi-Wei Sun and Qing-Hu Hou conjectured that a(n)>0 for n=6,7,...; in other words, any integer n>5 can be written as the sum of an odd prime, a positive Pell number and a companian Pell number. The Pell numbers are defined by P_0=0, P_1=1 and P_{n+1}=2P_n+P_{n-1} (n=1,2,3,...) and the companion Pell numbers are given by Q_0=Q_1=2 and Q_{n+1}=2Q_n+Q_{n-1} (n=1,2,3...). Note that for n>5 both P_n and Q_n are greater than 2^n. _D. S. McNeil_ disproved the conjecture by finding the 4 initial counterexamples: 169421772576, 189661491306, 257744272674, 534268276332. - _Zhi-Wei Sun_, Jan 17 2009 On Feb 01 2009, Zhi-Wei Sun observed that these 4 counterexamples are divisible by 42 and guessed that all counterexamples to the conjecture of Sun and Hou should be multiples of 42. - _Zhi-Wei Sun_, Feb 01 2009

V3-004931 | OEIS-A154404

Number of ways to express n as the sum of an odd prime, a positive Fibonacci number and a Catalan number.

Motivated by _Zhi-Wei Sun_'s conjecture that each integer n>4 can be expressed as the sum of an odd prime, an odd Fibonacci number and a positive Fibonacci number (cf. A154257), during their visit to Nanjing Univ. Qing-Hu Hou (Nankai Univ.) and Jiang Zeng (Univ. of Lyon-I) conjectured on Jan 09 2009 that a(n)>0 for every n=5,6,.... and verified this up to 5*10^8. _D. S. McNeil_ has verified the conjecture up to 5*10^13 and Hou and Zeng have offered prizes for settling their conjecture (see Sun 2009).

猜想/问题提及段 | historical_or_current_mention_unreviewed | Qing-Hu Hou (hou(AT)nankai.edu.cn), Jan 09 2009, Jan 18 2009 | 2026-10-24

V3-004932 | OEIS-A154417

Number of ways to express n as the sum of an odd prime, a positive Fibonacci number and half of a positive Fibonacci number.

On Jan 09 2009, _Zhi-Wei Sun_ conjectured that a(n)>0 for every n=5,6,...; in other words, any integer n>4 can be written in the form p+F_s+F_{3t}/2 with p an odd prime and s,t>0. Sun verified this up to 5*10^6 and Qing-Hu Hou continued the verification (on Sun's request) up to 3*10^8. Note that 932633 cannot be written as p+F_s+F_{3t}/2 with p a prime and (F_s or F_{3t}/2) odd. If we set u_0=0, u_1=1

and u_{n+1}=4u_n+u_{n-1} for n=1,2,3,..., then F_{3t}/2=u_t is at least 4^{t-1} for each t=1,2,3,.... In a recent paper K. J. Wu and Z. W. Sun constructed a residue class which contains no integers of the form p+F_{3t}/2 with p a prime and t nonnegative.

V3-004934 | OEIS-A154536

Positive integers that can be written as the sum of a positive Pell number and twice a positive Pell number.

On Jan 10 2009, _Zhi-Wei Sun_ conjectured that any integer greater than 5 can be expressed as the sum of an odd prime and a term in the above sequence; in other words, each n=6,7,... can be written in the form p+P_s+2*P_t with p an odd prime and s,t>0. This has been verified up to 5*10^13 by _D. S. McNeil_ (from London Univ.). Motivated by this conjecture, Qing-Hu Hou (from Nankai Univ.) observed and _Zhi-Wei Sun_ proved that each term a(n) in the above sequence can be uniquely written in the form P_s+2P_t with s,t>0. Sun noted that 2176 cannot be written as the sum of a prime and two Pell numbers; _D. S. McNeil_ found that 393185153350 cannot be written in the form p+P_s+3P_t and 872377759846 cannot be written in the form p+P_s+4P_t, where p is a prime and s and t are nonnegative. _Zhi-Wei Sun_ has offered a monetary reward for settling this conjecture.

V3-004936 | OEIS-A154752

Least prime p (or 0) such that n = p + T, where T is a triangular number (A000217), or -1 if there is no such representation.

Zhi-Wei Sun conjectures that only n=216 has no such representation. It appears that n = 2, 7, 61 and 211 are the only numbers for which the triangular number 0 is required in the representation (see A065397). When n is a triangular number, then a(n)=0. Sequence A132399 gives the number of representations of n as p+T. As n becomes larger, the largest prime required to verify the conjecture increases slowly. For example, for n<=10^3, the largest prime required is 953; for n<=10^6 it is 373361; for n<=10^9 it is only 36455351. Using primes less than 10^9, all n<243277591560 have been verified.

V3-004951 | OEIS-A155587

Expansion of (1 + x*c(x))/(1 - x), where c(x) is the g.f. of A000108.

To prove _R. J. Mathar_'s conjecture, note that the o.g.f. of the sequence implies (Sum_{n >= 0} a(n)*x^n)*(1 - x) = 1 + x*c(x); i.e., a(0) + Sum_{n >= 1} (a(n) - a(n-1))*x^n = 1 + Sum_{n >= 1} C(n-1)*x^n, where C(n) = A000108(n) (Catalan numbers). Thus, C(n-1) = a(n) - a(n-1) (for n >= 1), and hence C(n) = a(n+1) - a(n). Since 2*(2*n - 1)*C(n-1) = (n + 1)*C(n), we get (n + 1)*a(n+1) + (-5*n + 1)*a(n) + 2*(2*n - 1)*a(n-1) = 0. The last equation implies _R. J. Mathar_'s conjecture. (End) Conjecture: n*a(n) + (6-5*n)*a(n-1) + 2*(2*n-3)*a(n-2) = 0. - _R. J. Mathar_, Nov 15 2011

V3-004952 | OEIS-A155828

Number of integers k in {1,2,3,..,n} such that kn+1 is a square.

Conjecture: All terms a(n) are of the form 2^m - 1. This has been verified up to n = 1000. The conjecture that a(n) is of the form 2^m - 1 holds trivially. In fact, the conjecture can be restated as follows: For any positive integer n, the solutions of the congruence x^2 = 1 (mod n) with 1 <= x <= n is a power of two. By the Chinese remainder theorem, this reduces to the case when n is a prime power. It is well known that the solution of x^2 = 1 (mod p^a) is two when p is an odd prime (one may obtain this by induction on a). As for the number of solutions of the congruence x^2 = 1 (mod 2^a), it equals 1, 2, 4 according to whether a=1, 2, or a>2. - _Zhi-Wei Sun_, Feb 11 2009

V3-004954 | OEIS-A155860

Number of ways to write 2n-1 as p + 2^x + 3*2^y with p an odd prime and x,y positive integers.

On Jan 21 2009, _Zhi-Wei Sun_ conjectured that a(n)>0 for n=6,7,...; in other words, any odd integer m>10 can be written as the sum of an odd prime, a positive power of 2 and three times a positive power of 2. Sun verified this for odd integers m<10^7. On Sun's request, Qing-Hu Hou and _Charles R Greathouse IV_ continued the verification for odd integers below 2*10^8 and 10^10 respectively and found no counterexamples. As 3*2^y = 2^y + 2^{y+1}, Sun's conjecture implies that each odd integer m>8 can be written as the sum of an odd prime and three positive powers of two. Note that Paul Erdős asked whether there is a positive integer r such that every odd integer m>3 can be written as the sum of a prime and at most r powers of 2.

V3-004956 | OEIS-A155904

Number of ways to write 2n-1 as p+2^x+5*2^y with p an odd prime and x,y positive integers.

On Jan 21 2009, _Zhi-Wei Sun_ conjectured that a(n)>0 for n=8,9,...; in other words, any odd integer m>=15 can be written as the sum of an odd prime, a positive power of 2 and five times a positive power of 2. Sun has verified this for odd integers m<10^8. As 5*2^y=2^y+2^{y+2}, the conjecture implies that each odd integer m>8 can be written as the sum of an odd prime and three positive powers of two. [It is known that there are infinitely many positive odd integers not of the form p+2^x+2^y (R. Crocker, 1971).] Sun also conjectured that there are infinitely many positive integers n with a(n)=a(n+1); here is the list of such positive integers n: 1, 2, 3, 4, 5, 6, 9, 10, 11, 19, 24, 36, 54, 60, 75, 90, 98, 101, 105, 135, 153, 173, ...

V3-004959 | OEIS-A156164

Decimal expansion of 17 + 12*sqrt(2).

Conjecturally, the fractional part 0.97056 27484 ... of this constant equals ((1 + 2 * Sum_{n >= 1} (-1)^n*exp(-2*Pi*n^2))/(1 + 2 * Sum_{n >= 1} exp(-2*Pi*n^2)))^4. The series are rapidly converging. For example, summing both series from n = 1 to n = 2 approximates the fractional part of the constant as ((1 - 2*exp(-2*Pi) + 2*exp(-8*Pi))/(1 + 2*exp(-2*Pi) + 2*exp(-8*Pi)))^4 = 0.97056 27484 77140 58562 026(89) ..., correct to 23 decimal places. - _Peter Bala_, Jun 05 2019

V3-004976 | OEIS-A156695

Odd numbers that are not of the form p + 2^a + 2^b, a, b > 0, p prime.

All members above 5 found so far (up to 2.5 * 10^11) are divisible by 255 = 3 * 5 * 17, and many are divisible by 257. I conjecture that all members of this sequence greater than 5 are divisible by 255. This implies that all odd numbers (greater than 7) are the sum of a prime and at most three positive powers of two. All terms > 5 are numbers k > 3 such that k - 2^n is a de Polignac number (A006285) for every n > 0 with 2^n < k. Are there numbers K such that |K - 2^n| is a Riesel number (A101036) for every n > 0? If so, ||K - 2^n| - 2^m| is composite for every pair m,n > 0, by the dual Riesel conjecture. - _Thomas Ordowski_, Jan 06 2024 In keeping with the example's connection to A000215, the lowest ki for ki * Product_{i=0..11} (F(i)) to belong to A156695 are 1, 433007, 25471, 17047, 1291, 7, 101, 807, 83, 347, 9, 179. So for example, 433007*(3*5) is a term. This implies a variant of the first commented conjecture accordingly. - _Bill McEachen_, Apr 17 2025

V3-004995 | OEIS-A157218

Number of ways to write the n-th positive odd integer in the form p+2^x+7*2^y with p a prime congruent to 1 mod 6 and x,y positive integers.

On Feb 24 2009, _Zhi-Wei Sun_ conjectured that a(n)>0 for all n=18,19,...; in other words, any odd integer greater than 34 can be written as the sum of a prime congruent to 1 mod 6, a positive power of 2 and seven times a positive power of 2. Sun verified the conjecture for odd integers below 5*10^7, and Qing-Hu Hou continued the verification for odd integers below 1.5*10^8 (on Sun's request). Compare the conjecture with R. Crocker's result that there are infinitely many positive odd integers not of the form p + 2^x + 2^y with p an odd prime and x,y positive integers.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Feb 25 2009 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-004996 | OEIS-A157240

a(n) = A128018(n) + 1.

Generating floretion is Y = .5('i + 'j + 'k + i' + j' + k') + ee. ("tes"). Note: A current conjecture is that if X is a floretion for which 4*tes(X^n) is an integer for all n, then X+sigma(X) also has this property. "sigma" is the uniquely defined projection operator which "flips the arrows" of a floretion (i.e. sigma('i) = i', sigma('j) = j', etc.). Taking X = .5('i + 'j + 'k + ee), then tesseq(X) = [-1, -2, -1, 1, 2, 1, -1, -2, -1, 1, 2, 1, ...] is an integer sequence, thus by the conjecture 4*tes(Y^n) = 4*tes((X+sigma)^n) should also be an integer sequence for all n.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Creighton Dement_, Feb 25 2009 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-004997 | OEIS-A157242

Number of ways to write the n-th positive odd integer in the form p+2^x+11*2^y with p a prime congruent to 5 mod 6 and x,y positive integers.

On Feb. 24, 2009, Zhi-Wei Sun conjectured that a(n)=0 if and only if n<15 or n=17, 20, 23, 86, 124; in other words, except for 33, 39, 45, 171 and 247, any odd integer greater than 28 can be written as the sum of a prime p=5 (mod 6), a positive power of 2 and eleven times a positive power of 2. Sun verified the conjecture for odd integers below 5*10^7. Knowing the conjecture from Sun, Qing-Hu Hou and D. S. McNeil have continued the verification for odd integers below 1.5*10^8 and 10^12 respectively, and they have found no counterexample. Compare the conjecture with Crocker's result that there are infinitely many positive odd integers not of the form p+2^x+2^y with p an odd prime and x,y positive integers.

V3-005026 | OEIS-A158460

Numbers k such that prime(k-1) + 5 is square and equal to prime(k+1) - 1.

Conjecture: If the condition holds, prime(k-1) and prime(k) are twin primes of the form 10m+1 and 10m+3. I.e., the last digits are 1 and 3. This is so because prime(k-1)+5 square => possible ending digits of 0,1,4,5,6,9. To get ending digits for prime(k-1) we subtract 5 to get ending digits 5,6,9,0,1,4. So 1,9 are the only possible endings since 0,4,5,6 => prime(k-1) not prime, impossible. Now by the condition of equality, prime(k-1)+6 = prime(k+1). So if prime(k-1) ends in 9, prime(k-1)+6 ends in 5 => prime(k+1) not prime, impossible. Therefore prime(k-1) ends in 1 and by the condition of prime(k-1) and prime(k) being twin primes, prime(k) ends in 3. This sequence is a variation of the conjecture provided in the link.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-005028 | OEIS-A158470

Numbers k such that prime(k-1) + 7 is square and equal to prime(k+1) - 1.

Since prime(k-1) is prime, endings 2,4,5,8 are not allowed. This leaves us with 3,7,9 as possible endings of prime(k-1). Now to get prime(k), which the condition states is 2 greater than prime(k-1), we add 2 and 3+2=5 => prime(k) not prime, impossible. So the possible endings of prime(k-1) are reduced to 7 or 9. Now the condition prime(k-1)+7 = prime(k+1)-1 => prime(k-1)+8 = prime(k+1). Then adding 7 => prime(k+1) ends in 5, impossible. So prime(k-1) must end in 9, and adding 2 makes prime(k) end in 1. This

sequence is a calculation of the conjecture provided in the link. The PARI script provides for the general investigation of numbers of the form prime(k-1)+a and prime(k+1)-b. The values a=5,7; b=1 consistently yield twin primes when the condition holds.

V3-005031 | OEIS-A158509

Prime(n-1) such that prime(n-1)+5 is square and equal to prime(n+1)-1.

Conjecture: If the condition holds, prime(n-1) and prime(n) are twin primes of the form 10k+1 and 10k+3. I.e., the last digits of the primes are 1 and 3. The 1 ending is evident in the entries here. The conjecture is true: For p = prime(n-1) > 2 in this sequence we know that {p+1, p+3, p+5} are all even, p+6 = prime(n+1), p+5 = r^2 is a square, and p+4 = r^2-1 = (r-1)*(r+1) is composite. So p+2 = prime(n). Then p mod 10 = 1 because no prime > 5 has rightmost digit 5 and no square has rightmost digit 2. - _Alois P. Heinz_, Sep 07 2016

V3-005033 | OEIS-A158529

List of primes p with following properties: p = prime(m-1) for some m, p+7 is a square and is equal to prime(m+1)-1.

Conjecture: If the condition holds, prime(m-1) and prime(m) are twin primes of the form 10k+9 and 10k+11, i.e. the last digits of the twin prime pairs are 9 and 1. The 9 ending is obvious in this sequence. The table of the first 101 terms was computed using Zak Seidov's table. Proof of conjecture: Suppose p = prime(m-1) is a term with p + 7 = x^2. Now prime(m) must be p + 2 (it can't be p + 4 because one of p, p+4 and p+8 would be divisible by 3, and it can't be p + 6 = x^2-1 = (x-1)*(x+1)). As an even square, p + 7 ends in 0, 4 or 6, but it can't be 0 because p + 2 would be divisible by 5 and can't be 4 because p + 8 would be divisible by 5. The only possibility is that p + 7 ends in 6, i.e. p ends in 9. - _Robert Israel_, Jun 12 2026

V3-005068 | OEIS-A159907

Numbers m with half-integral abundancy index, sigma(m)/m = k+1/2 with integer k.

Conjecture: with number 1, multiply-anti-perfect numbers m: m divides antisigma(m) = A024816(m). Sequence of fractions antisigma(m) / m: {0, 0, 10, 2157, 2337, 13101, 4455356, ...}. - _Jaroslav Krizek_, Jul 21 2011 The above conjecture is equivalent to the conjecture that there are no odd multiply perfect numbers (A007691) greater than 1. Proof: (sigma(n)+antisigma(n))/n = (n+1)/2 for all n. If n is even then sigma(n)/n is a half-integer if and only if antisigma(n)/n is an integer. Since all members of this sequence are known to be even, the only way the conjecture can fail is if antisigma(n)/n is an integer, in which case sigma(n)/n is an integer as well. - _Nathaniel Johnston_, Jul 23 2011

V3-005120 | OEIS-A161681

Primes that are the difference between a cube and a square (conjectured values).

Primes that are the difference between a cube and a square (conjectured values). The primes found among the differences are sorted in ascending order and unique primes are then extracted. I call this a "conjectured" sequence since I cannot prove that somewhere on the road to infinity there will never exist an integer pair x,y such that x^3-y^2 = 3,5,17,..., missing prime. For example, testing x^3-y^2 for x,y up to 10000, the count of some duplicates are: Conjecture: The number of primes in x^3-y*2 is infinite. Conjecture: The number of duplicates for a given prime is finite. Then there is the other side - the primes that are not in the sequence 3, 5, 17, 29, 31, 37, 41, 43, 59, 73, 97, 101, 103, ... Looks like a lot of twin components here. Do these

have an analytical form? Is there such a thing as a undecidable sequence?

V3-005140 | OEIS-A162634

Numerators of fractions with denominators A000215(n) approximating the Thue-Morse constant.

One can prove that if in the sequence of numbers N for which A010060(N+2^n)= A010060(N) you replace the odious (evil) terms by 1's (0's), then we obtain 2^(n+1)-periodic (0,1)-sequence; if you write it in the form .xx...,i.e., as a binary infinite fraction, then the corresponding fraction has the form a(n)/A000215(n). These fractions very fast converge to the Thue-Morse constant .4124540336401...; e.g a(5)/(2^32+1) approximates this constant up to 10^(-9). These approximations differ from A074072-A074073. Conjecture. For n>=1, the fraction a(n)/A000215(n) is a convergent corresponding to the continued fraction for the Thue-Morse constant.

V3-005142 | OEIS-A162761

Minimal total number of floors an elevator must move to transport n people initially waiting at floors i = 1, ..., n to their destination floors n-i+1 (= n, ..., 1), when the elevator can hold at most one person at a time and starts at floor 1, and no passenger may get off the elevator before reaching his/her destination.

The value a(4) = 9 shows that it is not allowed to unload a passenger before he reaches his destination, cf. examples. This implies that there is no better solution than to transport person 1 to floor n, then person n to floor 1, then person 2 to floor n-1, then person n-1 to floor 2, etc., which yields a(n) = (Sum_{i=1..floor(n/2)} (n+1 - 2*i)*2 + 1) - 1 (for n > 1),

equal to the formula conjectured by C. Barker. It would be interesting to consider the variant of optimal solutions involving temporary drop-off of passengers. - _M. F. Hasler_, Apr 29 2019 a(n) = (n^2 + n + (-1)^n - 3)/2 for n > 1. a(n) = 2*a(n-1) - 2*a(n-3) + a(n-4) for n > 4. G.f.: x^2*(2+x^2-x^3)/((1-x)^3*(1+x)). - Conjectured by _Colin Barker_, Jun 10 2012, edited and proved by _M. F. Hasler_, Apr 29 2019

猜想/问题提及段 | historical_or_current_mention_unreviewed | Do Zerg (daidodo(AT)gmail.com), Jul 13 2009 | 2026-10-24

V3-005143 | OEIS-A162763

Minimal total number of floors an elevator must travel to get n people waiting, respectively, at floors i = 1, 2, ..., n, to their destinations at floors n+1-i (= n, ..., 1), if the elevator can hold at most C = 3 people and starts at floor 1, and no passenger may get off the elevator before reaching his/her destination.

The simple algorithm of taking the first C (or [n/2] if less) persons up to their destination, then the last C persons down to their destination, and if not finished, starting over with floor C+1 as new ground floor with n' = n - 2C, yields an upper bound a(n) <= 2n - 2 + C + a(n - 2C) for n > 2C + 1. In the example section we show that this is not optimal for n = 8 and 9, i.e., 2C + 2 and 2C + 3. I conjecture, however, that this upper bound is sharp (i.e., yields the exact result) for all n > 2C + 3. More precisely, I think the assumption of strict inequality for some larger value of n (the smallest such index) gives a proof by contradiction. - _M. F. Hasler_, May 15 2019 a(n) = 2n - 2 for n < 2C + 2 = 8, a(n) <= 2n - 2 + C + a(n - 2C) else, see comment for proof. Conjectured to hold with equality for all n except n = 2C + {2, 3} = {8, 9} where a(n) = 4(n - C) - 2 = 4n - 14. - _M. F. Hasler_, May 15 2019 G.f.: x*(2 + 2*x^6 - 2*x^7 + x^8 - x^9)/((1 - x)^3*(1 + x)*(1 - x + x^2)*(1 + x + x^2)) (conjectured). - _M. F. Hasler_, May 15 2019

V3-005152 | OEIS-A163553

First differences of A024816.

It appears that (1) a(n) = A120444(n)+1 if and only if n is a prime, (2) if a(n)<0 then A120444(n)<0, and (3) a(n)<=0 whenever n is of the form 6k-1. Are these conjectures easy to prove/disprove? (A120444 is the first difference of A004125 Sum of remainders of n mod k, for k = 1,2,3,...,n). We have a(n) - A120444(n) = sigma(n) - n. Hence a(n) = A120444(n) + 1 if and only if n is prime, and a(n) < 0 implies A120444(n) < 0. The conjecture that a(n) <= 0 whenever n == 5 (mod 6) is false and the first counterexample is a(65) = 6. - _Qiyuan Gu_, Aug 31 2026

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-005176 | OEIS-A164032

Number of "ON" cells in a certain 2-dimensional cellular automaton.

This box is full (more precisely, every cell in it has more than one ON neighbor), and at generation G+1 we have just 4 ON cells which are now at the corners of a box of edge 2G+1. Until the next power of 2 there is no interaction between the configurations that grow at the four corners, and so a(2^k+j) = 4a(j), as conjectured.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-005177 | OEIS-A164119

Numbers k that are the smallest number that produces the ordered pair (d(k), d(k+1)), where d(k) is the number of divisors of k.

The set of numbers that produces a given ordered pair (i,j) is either empty, finite, or infinite. The pair (3,3) is produced by no number because d(k)=3 only if k is the square of a prime and no two consecutive numbers are squares of primes. Sequence A161460 lists numbers k that produce a unique ordered pair. It appears that the ordered pair (4,2) is produced by an infinite number of k, which is another way of conjecturing that there are an infinite number of safe primes, A005385. The pair (2,4) is produced by primes in A005383. The numbers in A039832 produce the pair (4,4).

V3-005195 | OEIS-A164952

Primes p with the property: if p/3 is in the interval (p_m, p_(m+1)), where p_m>=3 and p_k is the k-th prime, then the interval (p, 3p_(m+1)) contains a prime.

For k>1 (not necessarily integer), we call a Ramanujan k-prime R_n^(k) the prime a_k(n) which is the smallest number such that if x >= a_k(n), then pi(x)- pi(x/k) >= n. Note that, the sequence of all primes corresponds to the case of "k=oo". These numbers possess the following properties: R_n^(k)~p_((k/(k-1))n) as n tends to the infinity; if A_k(x) is the counting function of the Ramanujan k-primes not exceeding x, then A_k(x)~(1-1/k)\pi(x) as x tends to the infinity; let p be a Ramanujan k-prime, such that p/k is in the interval (p_m, p_(m+1)), where p_m>=3 and p_n is the n-th prime. Then the interval (p, k*p_(m+1)) contains a prime. Conjecture. For every k>=2 there exist non-Ramanujan k-primes, which possess the latter property. For example, for k=2, the smallest such prime is 109. Problem. For every k>2 to estimate the smallest non-Ramanujan k-prime which possesses the latter property.

Quintisection A061037(5*n+2).

Conjecture: a(n) = 3*a(n-4) - 3*a(n-8) + a(n-12), n>11. - _R. J. Mathar_, Mar 02 2010 The conjecture is equivalent to a(4n) = 5n*(5n+1), a(4n+1) = 5*(20n+9)*(4n+1), a(4n+2) = 5*(10n+7)*(2n+1) and a(4n+3) = 5*(20n+19)*(4n+3). - _R. J. Mathar_, Feb 13 2011 The conjectures can be proved by taking the closed form of A061037, and writing up the quadrisections case by case. - _Bruno Berselli_, Feb 20 2011

V3-005211 | OEIS-A165300

a(n) is the smallest number not already present that permits the cyclic repetition of the path 1,2 of the digits in the sequence.

Conjecture. (1) If n > 1, and a(n) begins and ends with 1, then a(n+1) is obtained by deleting the initial 1 of a(n); (2) if a(n) begins with 1 and ends with 2 then a(n+1) is obtained by adding a final 1 to a(n); (3) if a(n) begins with 2 and ends with 1 then a(n+1) is obtained by adding a final 2 to a(n); (4) if a(n) begins and ends with 2 then a(n+1) is obtained by adding an initial 1 to a(n). This has been confirmed through a(140), which has 71 digits (and should be fairly easy to prove). - _John W. Layman_, Sep 22 2009

V3-005248 | OEIS-A166088

Odd integers (that is, of the form 2n+1) for which Sum_{i=1..u} J(i,2n+1) obtains value zero exactly 8 times, when u ranges from 1 to (2n+1). Here J(i,k) is the Jacobi symbol.

Of these eight, all are of the form 4k+1, and all others are primes except 65 (= 5*13) and 177 (= 3*59). Conjecture: There are no more terms after the eight one, 193. (Checked up to the 400000th term of A166040, i.e., up to A005408(400000)=800001.)

V3-005265 | OEIS-A166363

Number of primes in the half-open interval (n*(log(n))^2..(n+1)*(log(n+1))^2].

The Shanks Conjecture and the Cramer-Granville Conjecture tell us that the intervals of length (log(n))^2 are of very critical length (the constant M > 1 of the Cramer-Granville Conjecture definitely matters!). There seems to be some risk that one such interval does not contain a prime. The Wolf Conjecture (which agrees better with numerical evidence) seems more in favor of each interval's containing at least one prime. The similar sequence A345755 relies on intervals that are slightly more than twice as wide as those in the present sequence. A345755 does not include zero entries for n <= 2772, suggesting that the lengths of prime gaps may be bracketed by the two sequences. We conjecture that prime gaps may be larger than log(p)^2, but are not larger than log_2(p)^2. - _Hal M. Switkay_, Aug 29 2023

V3-005285 | OEIS-A167137

E.g.f.: P(exp(x)-1) where P(x) is the g.f. of the partition numbers (A000041).

CONJECTURE: Sum_{n>=0} a(n)^m * log(1+x)^n/n! is an integer series in x for all integer m>0; see A167138 and A167139 for examples. Conjecture: Let k be a positive integer. The sequence obtained by reducing a(n) modulo k is eventually periodic with the period dividing phi(k) = A000010(k). For example, modulo 16 we obtain the sequence [1, 1, 5, 15, 1, 7, 1, 7, 1, 7, ...], with an apparent period of 2 beginning at a(4). More generally, we conjecture that the same property holds for integer sequences having an e.g.f. of the form G(exp(x) - 1), where G(x) is an integral power series. (End)

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-005288 | OEIS-A167154

Numbers where terms in A167153 change parity: a(n)+1 is in A167153, but a(n)-1 is not.

Sequence A167153 consists of runs of numbers of the same parity. It is conjectured that each time the parity changes, there is a gap of 3 numbers, and the sequence goes on with the successor a(n)+1 (of opposite parity) of the first "missing" term a(n) in the run of terms of given parity (a(n-1)+1, a(n-1)+3, ..., a(n)-2).

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-005296 | OEIS-A167493

a(1) = 2; thereafter a(n) = a(n-1) + gcd(n, a(n-1)) if n is odd, and a(n) = a(n-1) + gcd(n-2, a(n-1)) if n is even.

Conjectures. 1) For n >= 2, every difference a(n) - a(n-1) is 1 or prime; 2) Every record of differences a(n) - a(n-1) greater than 3 belongs to the sequence of the greater of twin primes (A006512). Conjecture #1 above fails at n = 620757, with a(n) = 1241487 and a(n-1) = 1241460, difference = 27. Additionally, the terms of related A167495(m) quickly tend to index n/2. So for example, A167495(14) = 19141 is seen at n = 38284. - _Bill McEachen_, Jan 20 2023

Numbers that are congruent to {1, 8} mod 11.

Conjecture: For no term n>1 in the sequence 36*n^2+72*n+35 is equal to p*(p+2), where p, p+2 are twin primes. This conjecture is evident: in fact, it is sufficient to observe that a(2k) = 11*k-3 and a(2k+1) = 11*k+1, therefore 6*a(2k)+7 = 11*(6*k-1) and 6*a(2k+1)+5 = 11*(6*k+1). [_Bruno Berselli_, Jan 07 2013, modified Jul 07 2015]

V3-005356 | OEIS-A171884

Lexicographically earliest injective nonnegative sequence a(n) satisfying |a(n+1) - a(n)| = n for all n.

A correspondent, Dennis Reichard, conjectures that (i) a(n) <= 3.5*n for all n and (ii) the sequence covers 2/3 of all natural numbers. - _N. J. A. Sloane_, Jun 30 2018 [(i) is true: the indices of records for a(n)/n are n = 1, 2, 3, 4, 6, 7, and 2*3^k+2 for k >= 1, with record values 0, 1/2, 1, 1, 3/2, 7/6, 13/7, and (7*3^k-1)/(2*3^k+2) for k >= 1, so a(n) <= 3.5*n. (ii) needs further justification: the lower natural density is lim_{k->+oo} #{terms <= 7*3^k-2}/(7*3^k-2) = lim_{k->+oo} (4*3^k-1)/(7*3^k-2) = 4/7, and the upper natural density is lim_{k->+oo} #{terms <= 5*3^k-2}/(5*3^k-2) = lim_{k->+oo} (4*3^k-1)/(5*3^k-2) = 4/5. - _Jianing Song_, Oct 07 2022]

V3-005370 | OEIS-A172251

Arises in the representability of integers as sums of triangular numbers.

Wieb Bosma, p.10: Following the bounds given in the proof of Theorem 1.6, computational evidence suggests that... a proof of the above identity using the techniques of Bhargava and Hanke developed in the proof of the 290-Theorem may require a careful analysis of a possible Siegel zero. The sequence given is thus conjectured to be complete as shown.

V3-005374 | OEIS-A172468

Numbers such that A166986(n)/2 - A167389(n) = 1.

It is conjectured that the successive differences of this sequence, A172470, are limited to three numbers: 9, 52 and 61 where it is noted that 61 - 52 = 9, (52 + 2)/9 = 6, (61 + 2)/9 = 7 and we have lcm(9, 52, 61) = 28548 = 13^4 - 13 and 6 + 7 = 13. The conjectured closure of {9,52,61} then follows from plugging [IV] into [III] to get c = lim_{n->oo} c_n = 7/log(16) - 5/2 and by inspection of (n/log(2)) mod 1 for n <= 61, noting that -log(2)/2 satisfies [V] so that c_n satisfies [I] and [II]. Some basic pigeonholing further restricts the differences to three admissible runs [{52,9}, {61,61,9}, {61,61,61,9}] and issuing the sequence simplifies to evaluating ((n + 2)/log(2)) mod 1 once per run, comparing it to two constants, and measuring a low watermark for c_n as infrequently as possible.

V3-005387 | OEIS-A173238

Triangle by columns, A000041 in every column shifted down twice for columns > 0.

Conjectures: Given the infinite set of triangles with A000041 in every column shifted down 0, 1, 2, ... n times, row sums of n-th triangle (where A173238 = 2nd in the set) = the numbers of n's in all partitions of n. E.g., row sums = of A173238 = A024786, the numbers of 2's in all partitions of n. Second conjecture: Given the infinite set of analogous triangles with columns shifted down 2, 3, 4, ..., k times, we let such triangles = T(k) and perform lim_{n->inf} T^n(k), obtaining the left-shifted vectors considered as sequences.

The conjecture states that the infinite set of such left-shifted vectors = the Euler transform of the infinite set of Ruler functions starting with the ruler function for k=2 = A001511: (1, 2, 1, 3, 1, 2, 1, ...) Third conjecture: Let P(x) = polcoeff A000041 = (1 + x + 2x^2 + 3x^3 + ...), and A(k)(x) = the Euler transform of k-th ruler sequence, (k=2,3,...). Then P(x) = A(k)(x) / A(k)(x^k). The conjecture extends the analogous conclusions to all k. Proof of second conjecture received from Helmut Prodinger 02/28/10 with a summary by _R. J. Mathar_:

V3-005390 | OEIS-A173348

Numbers x such that 0 < |x^7 - y^2| < x^(5/2) for some number y.

Beukers and Stewart conjecture that for coprime integers n and m with n > m >= 2, and for any c > 0, the inequality 0 < |x^n - y^m| < c*X^(1-1/n-1/m) is true for infinitely many positive integers x and y, where X = max(x^n,y^m). They compute such x for 34 pairs (n,m). Given x, it is easy to compute y = round(x^(n/m)). Their tables have been extended to include all terms < 10^7 (or higher to obtain more terms).

V3-005391 | OEIS-A173419

Length of shortest computation yielding n using addition, subtraction and multiplication (starting from 1).

Conjecture: if n is prime then a(n) >= a(n-1). The conjecture is true for n < 1800. - _Dmitry Kamenetsky_, Dec 26 2019 The conjecture of Dmitry Kamenetsky above holds for every prime p < 3359, but fails at p = 3359, where a(3359) = 7 < 8 = a(3358); a shortest computation for 3359 = 15^3 - 16 is 1, 2, 4, 16, 15, 225, 3375, 3359. There are exactly four counterexamples below 5000: p = 3359; p = 3623 = 29*125 - 2, with a(3623) = 8 < 9 = a(3622), via 1, 2, 4, 5, 25, 125, 29, 3625, 3623; p = 4909 = 17^3 - 4, with a(4909) = 7 < 8 = a(4908), via 1, 2, 4, 16, 17, 289, 4913, 4909; and p = 4943 = 17*291 - 4, with a(4943) = 8 < 9 = a(4942), via 1, 2, 4, 16, 17, 289, 291, 4947, 4943. In each case the prime lies at short additive distance from a product of cheaply reachable numbers. Verified by exhaustive breadth-first enumeration of all computations of length <= 8 with no bound on intermediate values, extended to length 9 for the nine pairs (p, p-1) with p prime < 5000 left undecided at depth 8; all nine satisfy a(p) = a(p-1) = 9. - _Rosario Patanè_, Aug 28 2026

V3-005393 | OEIS-A173518

Solutions z of the Diophantine equation x^3 + y^3 = 6z^3.

A. Nitaj proved Erdős's conjecture (1975) and claimed that there exist infinitely many triples of 3-powerful numbers a,b,c with (a,b) = 1, such that a+b=c, because the equation x^3 + y^3 = 6z^3 admits an infinite number of solutions, and given by the recurrence equations (see formula). It is proved that a=x(k)^3, b=y(k)^3, and c=6c^3, and are 3-powerful numbers for each k >= 1.

V3-005403 | OEIS-A173774

The arithmetic mean of (21*k + 8)*binomial(2*k,k)^3 (k=0..n-1).

On Feb 10 2010, _Zhi-Wei Sun_ introduced the sequence and conjectured that each term a(n) is an integer divisible by 4*binomial(2*n,n). On Feb 11 2011, _Kasper Andersen_ confirmed this conjecture by noting that the sequence b(n) = a(n)/(4*binomial(2*n,n)), for n > 0, coincides with A112029. It was proved that for every prime p and positive integer a we have a(p^a) == 8 + 16*p^3*B_(p-3) (mod p^4), where B_0, B_1, B_2, ... are Bernoulli numbers. Given a prime p, it has been conjectured that Sum_{k=0..(p-1)/2} (21*k + 8)*binomial(2*k,k)^3 == 8*p + (-1)^((p-1)/2)*32*p^3*E_(p-3) (mod p^4) if p > 3 (where E_0, E_1, E_2, ... are Euler numbers), and that Sum_{k=0..floor(2p^a/3)} (21*k + 8)*binomial(2*k,k)^3 == 8*p^a (mod p^(a + 5 + (-1)^p)) if a is a positive integer with p^a == 1 (mod 3). He also observed that b(n) = a(n)/(4*binomial(2*n,n)) is odd if and only if n is a power of two.

V3-005426 | OEIS-A174341

a(n) = Numerator of Bernoulli(n, 1) + 1/(n+1).

Conjecture: the numerator of (A164555(n)/(n+1) + A027642(n)/(n+1)^2) is a(n) and the denominator of this fraction is equal to 1 if and only if n+1 is prime or 1. Cf. A309132. - _Thomas Ordowski_, Jul 09 2019 The "if" part of the conjecture is true: see the theorems in A309132 and A326690. The values of the numerator when n+1 is prime are A327033. - _Jonathan Sondow_, Aug 15 2019

V3-005442 | OEIS-A174531

Coefficients of polynomials described below.

Conjectures: (1) all terms of the sequence are integers; (2) P_n(0) = (floor((n-1)/2))!*4^(floor((n-1)/2)); (3) if n is even, then the coefficients of P_n do not exceed the corresponding coefficients of P_(n-1) and the equality holds only for the last ones; (4) all coefficients of P_n, except of the last one, are multiples of n iff n is prime. More conjectures: For even x, P[x, 1] = (2^x - 1) (x/2)! / (x+1), and for odd x, P[x, 1] = (2^x - 1) ((x-1) / 2)!. - _Peter J. C. Moses_, Sep 28 2011 The sequence of polynomials R's for k >= 0 begins: 0, 1, n+4, n^2 + 11*n + 32, n^3 + 21*n^2 + 152*n + 384, n^4 + 34*n^3 + 443*n^2 + 2642*n + 6144, ... This formula proves the conjecture of V. Shevelev for P_n(0) and P. Moses for P_n(1). (End)

V3-005472 | OEIS-A175567

a(n) = (n!)^2 modulo n*(n+1)/2.

The conjecture above is true for every even power 2k with k >= 1. Proof: if n+1 is not an odd prime, n(n+1)/2 divides n! (see A069268). If n+1 = p is an odd prime, write n(n+1)/2 = h*p with h = n/2. Then (n!)^(2k) == 0 (mod h), and (n!)^(2k) == 1 (mod p) by Wilson's theorem. Because 2h == -1 (mod p), x = h*(p-2) = n(n-1)/2 satisfies x == 0 (mod h) and x == -2h == 1 (mod p), and 0 <= x < n(n+1)/2, so by the Chinese remainder theorem the residue is n(n-1)/2. - _Scott M. Foltz_, Sep 24 2026

V3-005477 | OEIS-A175669

Triangle of numerators of coefficients of the polynomial Q^(2)_m(n) defined by the recursion Q^(2)_0(n)=1; for m>=1, Q^(2)_m(n) = Sum_{i=1..n} i^2*Q^(2)_(m-1)(i). For m>=0, the denominator for all 3*m+1 terms of the m-th row is A202367(m+1).

Sequence {Q^(r)_m(x)} is defined by the recursion: Q^(r)_0(x)=1; for m>=1 and integer x=n, Q^(r)_m(n)=sum{i=1,...,n}i^rQ^(r)_(m-1)(i). By the induction, we see that polynomial Q^(r)_m(x) has degree (r+1)*m. Note that Q^(0)_m(n) is C(n+m-1,m), Q^(1)_m(n)=S(n+m,n), where S(k,l) are Stirling numbers of the second kind. Thus Q^(r)_m(x) is an r-generalization of binomial coefficients and Stirling numbers of the second kind. Moreover, for every r, LCM of denominators of the coefficients of Q^(r)_m(x) generate sequences of factorial type which possess important arithmetic properties. For r=0, it is n!, for r=1, it is A053657, for r=2,3,4 we obtain A202367, A202368, A202369. Denote the general term of the sequence corresponding to a given r by n!^(r) and, for 0<=m<=n, denote C^(r)(n,m)=n!^(r)/(m!^(r)*(n-m)!^(r). Then, for the "r-Pascal triangle", we have the following conjectural regularity: if a prime p==1 mod r, then the ((p-1)/r)-th row contains two 1's and numbers multiple of p. Cf. triangles A202917, A202941.

V3-005493 | OEIS-A176285

a(1) = 1, and then 4*(2*n + 1)^2*a(n+1) + n^2*a(n) = (205*n^2 + 160*n + 32)*binomial(2*n-1, n)^3 (n = 1, 2, 3, ...).

On Apr 04 2010, _Zhi-Wei Sun_ introduced this sequence and conjectured that each term a(n) is a positive integer. He also guessed that a(n) is odd if and only if n is a power of two. It is easy to see that 8*n^2*binomial(2*n,n)^2*a(n) equals Sum_{k=0..n-1} (205*k^2 + 160*k + 32)*(-1)^(n-1-k)*binomial(2*k,k)^5. Sun also conjectured that for any prime p > 5 we have Sum_{k=0..p-1} (205*k^2 + 160*k + 32)(-1)^k*binomial(2*k,k)^5 == 32*p^2 + 64*p^3*Sum_{k=1..p-1} 1/k (mod p^7) and Sum_{k=0..(p-1)/2} (205*k^2 + 160*k + 32)(-1)^k*binomial(2*k,k)^5 == 32*p^2 + 896/3*p^5*B_{p-3} (mod p^6), where B_0, B_1, B_2, ... are Bernoulli numbers. It is also remarkable that Sum_{n>0} (-1)^n(205*n^2 - 160*n + 32)/(n^5*binomial(2*n,n)^5) = -2*zeta(3) as proved by T. Amdeberhan and D. Zeilberger via the WZ method. Conjecture: the supercongruences a(n*p^r) == a(n*p^(r-1)) (mod p^(3*r)) hold for all primes p >= 5 and all positive integers n and r. (End)

V3-005497 | OEIS-A176494

Least m >= 1 for which |2^m - prime(n)| is prime.

Conjecture. For every odd prime p, the sequence {|2^n - p|} contains at least one prime. The record values of the sequence appear at n = 2, 10, 31, 68, 341, ... and are 3, 4, 47, 791, ... Note that up to now the value a(341) is not known. _Charles R Greathouse IV_ calculated the following two values: a(815)=16464, a(591)=58091 and noted that a(341) is much larger [private communication, May 27 2010]. - _Vladimir Shevelev_, May 29 2010

V3-005521 | OEIS-A176806

Consider asymmetric 1-D random walk with set of possible jumps {-1,+1,+2}. Sequence gives number of paths of length n ending at origin.

From this special Lagrange series derivation and the proof that the g.f. g from above coincides with G, the conjecture, given by _Joerg Arndt_ as a comment above, has been proved. This uses [t^n]phi(t)^n = (1/n!)*(d/dt)^n phi(t)^n, evaluated at t = 0, which appears in the considered Lagrange series.

V3-005533 | OEIS-A176898

a(n) = binomial(6*n, 3*n)*binomial(3*n, n)/(2*(2*n+1)*binomial(2*n, n)).

Zhi-Wei Sun formulated two conjectures concerning a(n) (see Conjectures 1.1 and 1.2 in Z.-W. Sun, "Products and sums divisible by central binomial coefficients" and Conjecture A89 in "Open conjectures on congruences"). The first conjecture states that Sum_{n=1..p-1} a(n)/(108^n) is congruent to 0 or -1 modulo a prime p > 3 depending on whether p is congruent to +-1 or +-5 modulo 12, respectively. The second conjecture asks about an exact formula for a companion sequence of a(n). Both conjectures as well as many numerical congruences involving a(n) and (2n+1)a(n) were solved by Kh. Hessami Pilehrood and T. Hessami Pilehrood, see the link below. (End)

V3-005564 | OEIS-A177316

Number of permutations of n copies of 1..4 with all adjacent differences <= 1 in absolute value.

See A103882 and A177317 through A177328 for the number of permutations of n copies of 1..k (for different values of k) with adjacent differences restricted in size. We conjecture that all these sequences satisfy the congruences A(n*p^k) == A(n*p^(k-1)) (mod p^(3*k)) for all positive integers n and k and any prime p >= 5. - _Peter Bala_, Jan 16 2020 Conjecture: a(n) = (1/3)*(A005259(n) + A005259(n-1)). Equivalently, a(n) = Sum_{k = 0..n} binomial(n,k)^2*binomial(n+k-1,k)^2. Cf. A103882. If true, then the sequence satisfies the recurrence a(n) = (2*(102*n^6 - 612*n^5 + 1462*n^4 - 1768*n^3 + 1143*n^2 - 382*n+52) * a(n-1) - (2*n-1)*(3*n^2 - 3*n+1) * (n-2)^3 * a(n-2)) / (n^3*(2*n - 3) * (3*n^2 - 9*n+7)) and the supercongruences a(n*p^k) == a(n*p^(k-1)) (mod p^(3*k)) for all positive integers n and k and any prime p >= 5. [added Apr 18 2022: assuming the recurrence given in the Maple program below is correct then these conjectures are true.] (End)

V3-005601 | OEIS-A178456

Primes p such that p-1 or p+1 has more than two distinct prime divisors.

Sequence contains many pairs of twin primes. More exactly, denote A(x), t(x),T(x) the counting functions of this sequence, twin primes in this sequence and all twin primes correspondingly. In supposition of the infinitude of twin primes, the very plausible conjectures are: (1) for x tends to infinity, t(x)~T(x) and (2) for x >= 31, t(x)/A(x) > T(x)/pi(x).

Indeed (heuristic arguments), the middles of twin pairs (beginning with the second pair) belong to progression {6*n}. Let us choose randomly n. The probability that n has prime divisors 2,3 only is, as well known, O((log n)^2/n), i.e. it is quite natural to conjecture that almost all twin pairs are in the sequence. Besides, it is natural to conjecture that the inequality is true as well, since A(x)<pi(x).

V3-005614 | OEIS-A178785

a(n) is the smallest n-perfect number of the form 2^(n+1)*L, where L is an odd number with exponents <= n in its prime power factorization, and a(n)=0 if no such n-perfect number exists.

Let k >= 1. In the multiplicative basis Q^(k) = {p^(k+1)^j, p runs through A000040, j=0,1,...} every positive integer m has a unique factorization of the form m = Product_{q is in Q^(k)} q^(m_q), where m_q is in {0,1,...,k}. In particular, in the case of k=1, we have the unique factorization over distinct terms of A050376. Notice that the standard prime basis is the limiting value for k tending to infinity, and, by the definition, Q^(infinity)=A000040. The number d is called a k-divisor of m if the exponents d_q in its factorization in the basis Q^(k) do not exceed m_q. A number m is called k-perfect if it equals to the sum of its proper positive k-divisors. Conjecture: a(11)=0. Note that we also know of n-perfect numbers for n = 12, 14, 15, 16, and 18.

V3-005641 | OEIS-A179238

Numerators in convergents to infinitely repeating period 3 palindromic continued fraction [1,2,1,...].

Conjecture relating palindromic continued fractions to the tangents of angles A and 2A: The conjecture applies to any palindromic form such as [a,a,a,...], [a,b,a,a,b,a,...], [a,b,b,a,a,b,b,a,...], [a,b,c,c,b,a,...] and so on. Conjecture proved by the author, Jul 05 2010. - _Gary W. Adamson_, Mar 25 2014 Tan(2) corrected to tan(A), which is the half angle of a right triangle with sides (a, b) and c = sqrt(a^2 + b^2), not an integer. Example: Given a right triangle with sides a = 3, b = 5, c = sqrt(34), we calculate the two acute angles 2A and divide each by two, giving us two angles A; then perform tan(A) on each. These have an algebraic equivalency of two constants: 3/(5 + sqrt(34)) = 0.276983964... and 5/(3 + sqrt(34)) = 0.566190378... The continued fraction representations of these constants are respectively barover[3,1,1,1,1,3] and barover[1,1,3,3,1,1], both palindromic. The conjecture and proof don't apply to Pythagorean triangles, in which case the tangents of the half angles would be rational. - _Gary W. Adamson_, Apr 07 2014

V3-005652 | OEIS-A179481

a(n) = 2*t(n)-1 where t(n) is the sequence of records positions of A179480.

In answer to the primality question and pursuant to the Coach Theorem of Hilton and Pedersen: phi(b) = 2 * k * c, with b an odd integer and k in A003558, and c (the numbers of coaches) in A135303; iff phi(b) = (b-1) then b = p, prime. This implies that if b has one coach and k = (b-1)/2, b must be prime since phi(b) = 2 * k * c = 2 * (b-1)/2 * 1 = (b-1). Conjectures: all terms in A179481 have one coach with k = (b-1)/2 and are therefore primes. Next, if A179480(n) is a new record high value, then so is A003558(n-1); but not necessarily the converse (e.g. 13), and the corresponding value of k for b is (b-1)/2. Examples: b = 13 has one coach with k (sum of bottom row terms) = 6 = A003558(6); and r (number of entries in each row) = 3:

V3-005696 | OEIS-A180323

Positive numbers l of the form l = A007913(k^4 - 4*k*m^3), where 1 <= k <= 5*l, 1 <= |m| <= 5*l.

The equation x^3 + y^3 + z^3 = 0 is solvable in numbers of the form N + M*sqrt(a(n)), where M and N are integers. Moreover, it is solvable in numbers of the form N + M*sqrt(l), where l has the form l = A007913(k^4 - 4*k*m^3), where k,|m| >= 1 (without restrictions k,|m| <= 5*l). But in this more general case there could be unknown numbers l having this form; this circumstance does not allow construction of the full sequence of such l. Therefore we restrict ourselves by the condition k,|m| <= 5*l. Note that testing l with respect to this condition is rather simple by sorting all values of k,|m| <= l. One can prove that, at least, if the Fermat numbers (A000215) are squarefree, then the sequence is infinite. Conjecture (necessity of the form of l): If the equation x^3 + y^3 + z^3 = 0 is solvable in numbers of the form N + M*sqrt(l) with integer N,M, then there exist positive integers k,m such that l = A007913(k^4 - 4*k*m^3).

V3-005697 | OEIS-A180336

Positive numbers l of the form l = A007913(4*k*m^3 - k^4), where 1 <= k <= 5*l, 1 <= m <= 5*l.

The equation x^3 + y^3 + z^3 = 0 is solvable in numbers of the form N + M*sqrt(-a(n)), where M and N are integers. Moreover, it is solvable in numbers of the form N + M*sqrt(-l), where l>0 has the form l = A007913(4*k*m^3 - k^4), where k,m >= 1 (without restrictions k,m <= 5*l). But in this more general case there could be unknown numbers l having this form; this circumstance does not allow construction of the full sequence of such l. Therefore we restrict ourselves by the condition k,m <= 5*l. Note that testing l with respect to this condition is rather simple by sorting all values of k,m <= l. One can prove that, at least, in case the Fermat numbers (A000215) are squarefree, the sequence is infinite. Conjecture (necessity of the form of l): If the equation x^3 + y^3 + z^3 = 0 is solvable in numbers of the form N + M*sqrt(-l) with integer N,M, then there exist positive integers k,m such that l = A007913(4*k*m^3 - k^4).

V3-005713 | OEIS-A181018

Maximum number of 1's in an n X n binary matrix with no three 1's adjacent in a line along a row, column or diagonally.

Three or more "1"s may be adjacent in an L-shape or step shape (cf. bottom of first example) or 2 X 2 square (top right of 2nd example) or similar. One possible (not always optimal) solution is therefore to fill the square with 2 X 2 squares of "1"s, separated by rows of "0"s: this yields the lower bound (n - floor(n/3))^2 = ceiling(2n/3)^2 given in FORMULA. I conjecture that this is optimal for n = 2 (mod 3) and that a(n) ~ (2n/3)^2. For n = 3k, the array can be filled with 2k(2k+1) "1"s by repeating the optimal solution for n = 3 on the diagonal, and filling the rest with 2 X 2 blocks separated by rows of "0"s, cf. the 4th example for 6 X 6. - _M. F. Hasler_, Jul 17 2015 [Conjecture proved to be wrong, see below. - _M. F. Hasler_, Jan 19 2016]

V3-005736 | OEIS-A181547

a(n) = Sum_{k=0..floor(n/2)} C(n-k,k)^5.

Conjecture: Given F(n,L) = Sum_{k=0..[n/2]} C(n-k,k)^L, then lim_{n->oo} F(n+1,L)/F(n,L) = (Fibonacci(L)*sqrt(5) + Lucas(L))/2 for L>=0 where Fibonacci(n) = A000045(n) and Lucas(n) = A000032(n).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Paul D. Hanna_, Oct 29 2010 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-005737 | OEIS-A181553

Coefficient of x^n in (x^2 + 98*x + 1)^n.

On Jan 29 2011, _Zhi-Wei Sun_ conjectured that Sum_{k>=0} (40k + 3)*a(k)*binomial(4k, 2k)*binomial(2k, k)/112^(2k) = 70*sqrt(21)/(9*Pi). He also conjectured that 2n(2n + 1)*binomial(2n, n) divides Sum_{k=0..n-1} (40k + 3)*a(k)*binomial(4k, 2k)*binomial(2k, k)112^{2(n - 1 - k)} for each n = 2, 3, 4, ... and that for any prime p different from 2 and 7 we have the congruence Sum_{k=0..p-1} (40k + 3)*a(k)*binomial(4k, 2k)*binomial(2k, k)/112^(2k) == p(-21/p)(5 - 2(-2/p)) (mod p^2). Another conjecture of his states that for any prime p == 1, 3 (mod 8) with p = x^2 + 2y^2 (x, y integers) we have Sum_{k=0..p-1} a(k)*binomial(4k, 2k)*binomial(2k, k)/112^(2k) == (7/p)(4x^2 - 2p) (mod p^2). By a result of Sun, Sum_{k=0..p-1} (40k + 3)*a(k)*binomial(4k, 2k)*binomial(2k, k)/112^(2k) == 0 (mod p^2) for any prime p = 5,7 (mod 8).

V3-005759 | OEIS-A182090

Carmichael numbers divisible by 11.

Conjecture: Any Carmichael number C divisible by 11 and not divisible by 3 can be written in one of the following four forms: C = 990k+11; C = 990k+11^2; C = 990k+11*41 or C = 990k+11*71, where k is a natural number. For comparison, we issue the following related conjectures: The first counterexample to the conjecture is 6049681 which is 781 mod 990. 341 and 671 mod 990 also appear. Conjecture 1 is true; the only excluded possibility is 161 mod 210 which is never a 2-pseudoprime (check mod 7). All three parts of conjecture 2 are false; counterexamples include 461502097, 1378483393, and 7044493729. Conjecture 3 is true, consider Korselt's criterion mod 30. - _Charles R Greathouse IV_, Dec 07 2014

V3-005770 | OEIS-A182187

a(n) is the least m >= n such that the Hamming distance D(n,m) = 2.

Using this formula, we can prove the conjecture formulated in comment in A209554 in the case k=2. Moreover, let us show that if N does not have the form 8*t or 8*t+1, then it can be represented in the form n<+>2. Indeed, in the cases N = 8*t+2, 8*t+4, 8*t+6, 8*t+3, 8*t+5 and 8*t+7 it is sufficient to choose n=N-4, n=N-2, n=N-1, n=N-3, n=N-2 and n = N-3 respectively; in the cases 8*t, 8*t+1, for every choice of n <= N, we do not obtain the equality n<+>2 = N.

V3-005835 | OEIS-A183299

Complement of A005563.

Defining the probability for integer value x in a Poisson distribution of integer mean = q > 0 as P(q,x) = e^(-q)*(q^x)/x! then it is conjectured that P(n, a(n)+1)- P(n, a(n)) <= P(n, k+1)- P(n, k), for every k > 0.

V3-005878 | OEIS-A183978

1/4 the number of (n+1) X 2 binary arrays with all 2 X 2 subblock sums the same.

Based on the conjectured recursion formula, it is also the number of notches in a sheet of paper when you fold it n times and cut off the four corners (see A274230). - _Philippe Gibone_, Jul 06 2016 Based on the conjectured recursion formula, we may prove (by a tedious induction) that a(n) = (2^ceiling(n/2) + 1) * (2^floor(n/2) + 1) = A051032(n) * A051032(n-1) for n >= 1. - _Philippe Gibone_, Jul 06 2016, corrected by _Robert Israel_, May 21 2019

V3-005911 | OEIS-A184423

a(n) = (2*n)!*(3*n)!/n!^5.

Inductively define a family of sequences {a(i,n) : n >= 0}, i >= 1, by setting a(1,n) = a(n) and, for i >= 2, a(i,n) = [x^n] (exp(Sum_{k >= 1} a(i-1,k)*x^k/k))^n. We conjecture that the sequences {a(i,n) : n >= 0}, i >= 2, also satisfy the supercongruences u(n*p^r) == u(n*p^(r-1)) (mod p^(3*r)) for primes p >= 5 and positive integers n and r. Cf. A362730 and A362732. (End)

V3-005924 | OEIS-A184774

Primes of the form floor(k*sqrt(2)).

The conjecture formerly posted here, that "if r is an irrational number and 1<r<2, then there are infinitely many primes in the set L={floor(n*r)}," is proved in I. M. Vinogradov, The Method of Trigonometrical Sums in the Theory of Numbers, (1954), page 180. The conjecture generalized: if r is a positive irrational number and h is a real number, then each of the sets {floor(n*r+h)}, {round(n*r+h)}, and {ceiling(n*r+h)} contains infinitely many primes. Can the method in Vinogradov be extended to cover these cases? [Update regarding the conjecture from _Clark Kimberling_, Jan 03 2011.]

V3-005954 | OEIS-A185636

a(n) = |{0 <= k < n: n+k and n+k^2 are both prime}|.

Conjecture: a(n) > 0 for all n > 1. This conjecture has been verified for n up to 10^8. It is stronger than Bertrand's postulate proved by Chebyshev in 1850. Zhi-Wei Sun also guessed the following refinement of the conjecture: For any integer n > 1456 there is an integer k among 0,...,n-1 such that n-k, n+k and n+k^2 are all prime; in other words, there is a prime p <= n such that 2n-p and n+(n-p)^2 are both prime. For other refinements of the conjecture, the reader may consult arXiv:1211.1588. The author also conjectured the following polynomial analogs: In a 2017 paper, the author announced a USD $100 prize for the first solution to his conjecture that for each n = 1,2,3,... there is an integer k among 0,...,n such that n+k and n+k^2 are both prime. - _Zhi-Wei Sun_, Dec 03 2017

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Dec 18 2012 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-005955 | OEIS-A185645

Number of permutations q_1,...,q_n of the first n primes p_1,...,p_n with q_1 = p_1 = 2 and q_n = p_n, and with |q_1-q_2|, |q_2-q_3|, ..., |q_{n-1}-q_n|, and |q_n-q_1| (if n>2) pairwise distinct.

Conjecture: a(n) > 0 for all n > 0. In general, for any n consecutive primes p_k,...,p_{k+n-1}, there always exists a permutation q_k,...,q_{k+n-1} of p_k,...,p_{k+n-1} with q_{k+n-1} = p_{k+n-1} such that the n-1 numbers |q_k-q_{k+1}|, |q_{k+1}-q_{k+2}|,...,|q_{k+n-2}-q_{k+n-1}| are pairwise distinct. (In the case k = 2, this implies that a(n) > 0.) On Aug 31 2013, Zhi-Wei Sun proved the following extension of the general conjecture: Let a_1 < a_2 < ... < a_n be a sequence of n distinct real numbers in ascending order. Then there is a permutation b_1, ..., b_n of a_1, ..., a_n with b_n = a_n such that |b_1-b_2|, |b_2-b_3|, ..., |b_{n-1}-b_n| are pairwise distinct. In fact, when n = 2*k is even we may take (b_1,...,b_n) = (a_k,a_{k+1},a_{k-1},a_{k+2},...,a_2,a_{2k-1},a_1,a_{2k}); when n = 2*k-1 is odd we may take (b_1,...,b_n) = (a_k,a_{k-1},a_{k+1},a_{k-2},a_{k+2},..., a_2,a_{2k-2},a_1,a_{2k-1}). On Sep 01 2013, Zhi-Wei Sun made the following conjecture: (i) For any n distinct real numbers a_1, a_2, ..., a_n (not necessarily in ascending or descending order), there is a permutation b_1, ..., b_n of a_1, ..., a_n with b_1 = a_1 such that the n-1 distances |b_1-b_2|, |b_2-b_3|, ..., |b_{n-1}-b_n| are pairwise distinct. We believe that part (ii) of the new conjecture holds at least when G is cyclic, and it might also hold when the group G is not abelian.

V3-005959 | OEIS-A185897

G.f. A(x) satisfies: A(x - A(x)^2) = x/(1-x).

Conjecture: for n > 1, a(n) is odd when n = 3*2^k through 4*2^k - 1 for k >= 0. - _Paul D. Hanna_, Oct 05 2025 The conjecture is true (see Preil link). Proof sketch: the defining equation determines A(x) uniquely over the integers, so it suffices to solve it mod 2. Over GF(2) put L(y) = Sum_{k>=0} y^(2^k), so that L(y)^2 + L(y) = y. Then B(x) = L(x + x^3)/(1 + x) satisfies B(x + B(x)^2) = x/(1 + x), because with u = x + B^2 one has u = L(x+x^3)/(1+x)^2 and L(u + u^3) = x(1+u)/(1+x), verified by the Artin-Schreier identity. Hence A(x) == L(x + x^3)/(1 + x) (mod 2), whose coefficients are 1 exactly for n = 1 and 3*2^k <= n <= 4*2^k - 1. - _Dovid Preil_, Oct 16 2026

Number of cycle-up-down permutations of {1,2,...,n} having no fixed points. A permutation is said to be cycle-up-down if it is a product of up-down cycles. A cycle (b(1), b(2), ...) is said to be up-down if, when written with its smallest element in the first position, it satisfies b(1)<b(2)>b(3)<... .

G.f.: conjecture: T(0), where T(k) = 1 - x^2*(k+1)*(k+2)/(x^2*(k+1)*(k+2) - 2*(1-x*k)*(1-x*(k+1))/T(k+1)); (continued fraction). - _Sergei N. Gladkovskii_, Nov 21 2013

V3-005988 | OEIS-A186388

Adjusted joint rank sequence of (f(i)) and (g(j)) with f(i) before g(j) when f(i)=g(j), where f(i)=6*i and g(j)=j*(j+1)/2 (triangular number). Complement of A186387.

Both conjectures from _Chai Wah Wu_ hold. Proof: Let T_n = n*(n+1)/2. In the joint ranking, there are n triangular numbers up to T_n. Since multiples of 6 are ranked before T_n in case of equality, the number of positive multiples of 6 counted up to T_n is floor(T_n/6). Hence a(n) = n + floor(T_n/6) = n + floor(n*(n+1)/12). Checking the residue classes of n modulo 12 shows that this formula gives the conjectured generating function; multiplying that generating function by its denominator gives the stated recurrence. - _Kaiming Sun_, Sep 03 2026 Conjectures from _Chai Wah Wu_, May 12 2026: (Start)

V3-006071 | OEIS-A187714

Odd numbers m divisible by 3 such that for every k >= 1, m*2^k - 1 has a divisor in the set {5, 7, 11, 13, 17, 19, 31, 37, 41, 61, 73, 109, 151, 241, 331}.

Conjecture: 7148695169714208807 is the smallest Riesel number that is divisible by 3. - _Arkadiusz Wesolowski_, May 12 2017

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Arkadiusz Wesolowski_, Mar 17 2011 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006072 | OEIS-A187754

Number of ways of writing the n-th twin prime p as p = q + r + s, where q >= r >= s are twin primes.

The author conjectures that a(n) >= 1 for all n >= 4. By Zhi-Wei Sun's conjecture related to A219157, for any positive integer n not among 1, 10, 430 we can write 6n-1 = p+2q = p+q+q with p,p-2,q,q+2 all prime, also for any integer n>702 we can write 6n+1 = 6(n-1)+7 = p+q+7 with p,p-2,q,q+2 all prime. Thus the author's conjecture is a consequence of Sun's conjecture. - _Zhi-Wei Sun_, Jan 06 2013

V3-006074 | OEIS-A187758

Number of ways to write n=x+y (x,y>0) with 2x-3, 2x+3, 6y+1 and 6y+5 all prime.

Conjecture: a(n)>0 for all n>4.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Jan 03 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006075 | OEIS-A187759

Number of ways to write n=x+y (0<x<y<n) with 6x-1, 6x+1, 6y-1 and 6y+1 all prime.

Conjecture: If n>200 is not among 211, 226, 541, 701, then a(n)>0. This essentially follows from the conjecture related to A219157, since n=x+y for some positive integers x and y with 6x-1,6x+1,6y-1,6y+1 all prime if and only if 6n=p+q for some twin prime pairs {p,p-2} and {q,q+2}. Similarly, the conjecture related to A218867 implies that any integer n>491 can be written as x+y (0<x<=y<n) with 6x+1, 6x+5, 6y+1 and 6y+5 all prime; and the conjecture related to A219055 implies that any integer n>1600 not among 2729 and 4006 can be written as x+y (0<x<=y<n) with 2x-3, 2x+3, 2y-3 and 2y+3 all prime.

V3-006076 | OEIS-A187761

Number of maps f: [n] -> [n] with f(x)<=x and f(f(x)) = f(f(f(x))).

Conjecture (confirmed below) about the e.g.f. A(x): Let B(x) = Sum_{n>=0} b(n) * x^n/n! = exp(exp(x)-1) the e.g.f. of the Bell numbers (A000110). Then A(x) = Sum_{n>=0} a(n) * x^n/n! = exp(Sum_{n>=0} b(n) * x^(n+1)/(n+1)!), see PARI program. Conjecture (confirmed below): Let C(0,x) = 1 and for k>=1 C(k, x) = exp(integral(C(k-1,x))) then C(k,x) is the e.g.f. for monotonic-labeled forests on n vertices with rooted trees of height less than k (column k of A179455(n,k) for k>=1, n>=k). For k=1 (C(1,x)=exp(x)) and k=2 (C(2,x)=exp(exp(x)-1)) this is known to be true, for k=3 this is the conjecture above. (End) "Which means the conjecture is right. (The integral turns that into 'multisets of things whose sizes plus 1 add up to n'; a tree is a forest together with a new node on top.)"

V3-006154 | OEIS-A189007

Number of ON cells after n generations of the 2D cellular automaton described in the comments.

Conjecture: a(1) = 1; a(n) = 2^A056791(n-1) for n > 1. - _Michael De Vlieger_, Nov 02 2022 It is not difficult to show that the preceding conjecture is correct. In fact one can give an explicit formula for the n-th term. At generation n >= 2, the configuration of ON cells consists of a set of concentric diamonds (see the illustration). The sizes of the diamonds are given by the (n-2)nd term of A245191. Let N = A245191(n-2) = Sum_{i>=0} b_i*2^i. Then the ON cells form a set of diamonds with edge-lengths i+2 for each b_i = 1. The i-th diamond contains 4*(i+1) ON cells, and the total number of ON cells is therefore a(n) = 4*Sum_i (i+1)*b_i. The b_i are given explicitly in A245191.

V3-006161 | OEIS-A189202

Let s_k(n) denote the sum of digits of n in base k. Then a(n) is the smallest m>0 such that both s_2(m*(n-1)) and s_n(2*m*(n-1))/(n-1) are even, or a(n)=0, if such m does not exist.

Conjecture: For all n>=2, a(n)>0.

V3-006162 | OEIS-A189281

Number of permutations p of 1,2,...,n satisfying p(i+2) - p(i) <> 2 for all 1 <= i <= n-2.

The conjectured recurrence would imply the asymptotic expansion for a(n)/n! ~ There are good reasons to believe the conjecture is correct. (It has the expected form.) The problem is one of counting Hamiltonian cycles in the complement of some simple graph. There is a method for counting these efficiently (although I have not implemented in code). Similar to A242522 / A229430. - _Andrew Howroyd_, Mar 06 2022 a(40)-a(300) were computed using an independent solution (dynamic programming, O(N^4) per term), and the conjectured recurrence was further confirmed to be correct up to n=300. Consequently, the keyword "hard" is removed. - _Rintaro Matsuo_, Oct 18 2022

Conjectured recurrence of degree 11 and order 8: (262711*n + 1387742*n^2 - 824875*n^3 - 1855253*n^4 - 111530*n^5 + 680983*n^6 + 364242*n^7 + 84992*n^8 + 10332*n^9 + 640*n^10 + 16*n^11)*a(n) + (-1050844*n - 9705192*n^2 - 7414683*n^3 + 3536494*n^4 + 6459004*n^5 + 3326393*n^6 + 903534*n^7 + 144684*n^8 + 13756*n^9 + 720*n^10 + 16*n^11)*a(n+1) + (3492344 - 2212342*n - 8507169*n^2 - 11544227*n^3 - 12034116*n^4 - 8216995*n^5 - 3442049*n^6 - 890050*n^7 - 142300*n^8 - 13660*n^9 - 720*n^10 - 16*n^11)*a(n+2) + (19817984 + 45323852*n + 825228*n^2 - 57004661*n^3 - 57059306*n^4 - 28077270*n^5 - 8398637*n^6 - 1631510*n^7 - 207980*n^8 - 16828*n^9 - 784*n^10 - 16*n^11)*a(n+3) + (9586160 + 6680237*n - 13772613*n^2 - 27689586*n^3 - 22162455*n^4 - 9855085*n^5 - 2629562*n^6 - 427656*n^7 - 41332*n^8 - 2176*n^9 - 48*n^10)*a(n+4) + (22192864 + 44710768*n - 2924668*n^2 - 52385912*n^3 - 45161616*n^4 - 18784740*n^5 - 4549208*n^6 - 674256*n^7 - 60400*n^8 - 3008*n^9 - 64*n^10)*a(n+5) + (557152 - 2032472*n - 2937392*n^2 - 1594200*n^3 - 517688*n^4 - 122032*n^5 - 19856*n^6 - 1792*n^7 - 64*n^8)*a(n+6) + (3786960 + 7105324*n - 1191064*n^2 - 8059160*n^3 - 5938996*n^4 - 2073752*n^5 - 402736*n^6 - 44528*n^7 - 2624*n^8 - 64*n^9)*a(n+7) + (-598208 - 943004*n + 414196*n^2 + 1213772*n^3 + 728648*n^4 + 203584*n^5 + 29616*n^6 + 2176*n^7 + 64*n^8)*a(n+8) = 0. This recurrence correctly predicted the four new terms in the b-file. - _Christoph Koutschan_, Feb 19 2022 The preceding conjectured recurrence is equivalent to the following, which has degree 3 and order 13, and was obtained by _Doron Zeilberger_ and then reformatted by _Manuel Kauers_ (it uses Mathematica syntax): Conjecture: ((-1 + n)^2*n*a[n])/4 + (n*(-16 + 38*n + 11*n^2)*a[1 + n])/16 +

V3-006200 | OEIS-A190213

Integers m such that m divides (2^m-2)^2 and (m-2)^((k-1)*(1+k*(m-1))) == 1 (mod k), where k = 2^m - 1.

Conjecture: All odd entries are also Mersenne exponents (A000043): primes n such that 2^n-1 is prime. Any exceptions to the conjecture are larger than 10^5. - _Charles R Greathouse IV_, Oct 03 2022

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Alzhekeyev Ascar M_, May 19 2011 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006201 | OEIS-A190273

Numbers n such that n' = m+1, with n and m semiprimes and gcd(m,n)>1, where n' is the arithmetic derivative of n.

The sequence is related to the Rassias Conjecture ("for any prime p there are two primes p1 and p2 such that p*p1=p1+p2+1, p>2, p2>p1", see A190272-A190275), because n = p1*p2, m=p1*p -> p1*p = p1+p2-1. The sequence includes the cases with p=p1 (or p2). Generalization can be achieved by removing semiprimarity condition or accepting gcd(n,m)=1. The differential equation in its general form n'=m+1 includes Giuga Numbers, i.e., n'=b*n+1, or n'=n+1 (A007850).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Giorgio Balzarotti_, May 07 2011 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006202 | OEIS-A190274

Numbers n such that n' = p^2-1, with n = semiprime = p*q, n' is the arithmetic derivative of n. Also: semiprimes of the form p*(p^2-p-1).

The sequence shows similarity with the Rassias Conjecture ("for any prime p there are two primes p1 and p2 such that p*p1=p1+p2+1, p>2, p2>p1") with p1=p we have p*p=p+p2-1 (see A190272). Generalization can be achieved by removing semiprimarity condition and accepting p^e, e>=2.

V3-006209 | OEIS-A190661

a(n) is the least number m such that there are at least n primes in the range (T(k-1), T(k)] for all k >= m, where T(k) is the k-th triangular number.

All values and even whether the sequence is well defined are conjectural. a(n) is the conjectured index of the last occurrence of n in A066888. It is conjectured that for every n >= 0, a(n) > n. With R_n the n-th Ramanujan prime (A104272), it is conjectured that for every n >= 0, (1/2) R_n <= a(n) < (20/13) R_n. These bounds have been verified for all n up to 8000. For most n <= 8000, we have a(n) > R_n, with exceptions listed in A190881.

V3-006225 | OEIS-A191257

a(n) = A067368(n)/2.

With the previous definition, a(n) = A067368(n)/2 was stated as a conjecture. _Jianing Song_, Sep 21 2018 showed that this is true, and gave us the simpler definition that we have now used. The conjecture is correct because {a(n)} lists the numbers of the form 2^(3t)*s, and {A067368(n)} lists the numbers of the form 2^(3t+1)*s, where s is an odd number. Note also that a(n) = A213258(n)/4.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006226 | OEIS-A191269

Fixed point of the morphism 0 -> 001, 1 -> 02, 2 -> 01.

Proof of Kimberling's conjecture on the positions of 0 in this sequence: consider the letter to letter projection pi given by pi(0) = 0, pi(1) = 1, pi(2) = 1. Then pi sigma = tau pi, where tau is the morphism on {0,1} given by tau(0) = 001, tau(1) = 01. It follows that pi(a) = x, where x = A188432 is the fixed point of tau. Note that the positions of zero in a = A191269 are equal to the positions of zero in x. Since x is the infinite Fibonacci word with a zero in front, it follows that these positions are given by A026351. - _Michel Dekking_, Aug 24 2019

V3-006261 | OEIS-A192062

Square Array T(ij) read by antidiagonals (from NE to SW) with columns 2j being the denominators of continued fraction convergents to square root of (j^2 + 2j).

Conjecture re relation of A192062 to the sequence of primes: T(2*n,j) = A(n,j)*T(n,j) where A(n,j) is from the square array A191971. There, A(3*n,j) = A(n,j)*B(n,j) where B(n,j) are integers. It appears further that B(5*n,j)=B(n,j)*C(n,j); C(7*n,j)= C(n,j)*D(n,j); D(11*n,j) = D(n,j)*E(n,j); E(13*n,j) = E(n,j)*F(n,j) and F(17*n,j) = F(n,j)*G(n,j) where C(n,j), D(n,j) etc. are all integers. My conjecture is that this property continues indefinitely and follows the sequence of primes.

V3-006264 | OEIS-A192189

Polynomial-like numbers: numbers whose sequence of number-derivatives (A003415) is monotonically decreasing.

Conjecture. For every sufficiently large greater q of twin primes, the sequence contains infinite increasing sequence {s_n} of semiprimes beginning with 2*(q-2), such that (s_n)'=s_(n-1). This conjecture is true, if 1) there exist infinitely many twin primes; 2) there exists n_0, such that for every prime p>n_0, number 2*p is sum of two primes r,t, for which r*t-2 is prime.

V3-006309 | OEIS-A192984

In repeated iterations of function m->m/3 if m == 0 (mod 3), m->4m+a if 4m+a == 0 (mod 3) where a = 1 or 2, a(n) is maximum value achieved if starting from n.

If a(n) exists (which is the conjecture of A194428) then a(n) must be a multiple of 9, since if a(n) is not divisible by 3 then the next iteration 4*a(n) + 1 or 4*a(n) + 2 would be greater than a(n), while if a(n) was divisible by 3 only once, a(n) = 3x -> x -> 4x+1 or 4x+2 is greater than 3x.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Michel Lagneau_, Aug 25 2011 | 2026-10-24

V3-006312 | OEIS-A193020

Number of distinct self-shuffles of the word given by the binary representation of n.

An examination of the terms of the sequence leads to the following conjectures (in each case with the caveat that k must exceed a certain lower bound): a(2^k-5)=3k-6, a(2^k-4)=k*(k-1)/2, a(2^k-3)=2k-2, a(2^k-2)=k, a(2^k-1)=1, a(2^k)=k+1, a(2^k+1)=k^2, a(2^k+2)=2*(k-1)^2, a(2^k+3)=k*(k-1)^2/2. To illustrate, consider a(2^k+1); we get, for k=1, 2, 3, ..., a(3)=1, a(5)=4, a(9)=9, a(17)=16, a(33)=25, a(65)=36, a(129)=49, a(257)=64,..., leading to the conjecture that a(2^k+1)=k^2. The other conjectures were arrived at in the same manner.

V3-006313 | OEIS-A193101

Minimal number of numbers of the form (m^3+5m)/6 (see A004006) needed to sum to n.

It is conjectured that a(n) <= 5 for all n.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _N. J. A. Sloane_, Jul 15 2011 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006314 | OEIS-A193138

Number of square satins of order n.

This sequence is conjectured to coincide with the multiplicities of the representation of n >= 3 as primitive sums of two squares. Neither the order of the squares nor the signs of the numbers to be squared are taken into account. a(n) = 0 if no such representation exists. Checked for n = 3,4, ..., 1000 (using the program below). The two squares are in each case nonzero and distinct. If one includes also 0 as a square in the primitive sum of two squares one could take a(0) = 0, a(1) = 1, a(2) = 1. If only nonzero squares are considered, then one could take a(0) = 0, a(1) = 0, a(2) = 1. For the numbers n with a(n) > 0 (in this conjectured interpretation of a(n)) see A008784. - _Wolfdieter Lang_, Apr 17 2013 The stated conjecture is true because it follows immediately from Theorem 3.22, p. 165, of the Niven-Zuckerman-Montgomery reference. There r(n) gives the number of primitive solutions of n = x^2 + y^2 with ordered and signed pairs of integers x,y. Because x and y are distinct if n >= 3 one needs here a(n) = r(n)/2^3. This then coincides with the formula for u(n) given in the Grünbaum-Shephard Theorem 5. - _Wolfdieter Lang_, Apr 18 2013

V3-006317 | OEIS-A193229

A double factorial triangle.

It appears that T(n,k) = (2*n-k)!/(2^(n-k)*(n-k)!) with conjectural e.g.f. 1/(x*(1-2*z) + (1-x)*sqrt(1-2*z)) = 1 + (1+x)*z + (3+3*x+2*x^2)*z^2/2! + ... Cf. A102625. - _Peter Bala_, Jul 09 2012 The conjectured formula above is valid. The production matrix gives T(n+1,0) = T(n+1,1), T(n+1,k)-T(n+1,k+1) = k*T(n,k-1) for 1 <= k <= n, and T(n,n) = n!. The displayed formula satisfies these relations and T(0,0)=1, which proves it by induction. - _Philip Weiss_, Jul 09 2026

V3-006323 | OEIS-A193358

a(0)=1; a(1)=2 and for n>1: a(n)=a(n-a(n-2))+2.

Conjecture: Every positive integer is in this sequence. Conjecture: Odd numbers are not repeated. Both conjectures are true. Sequence follows the pattern: for n = 0,1,2,..., the sequence consists of 2*n terms of value 2*(n+1), followed by the terms 2*n+1 and 2*(n+1). Thus 0 terms of 2 followed by 1 and 2, then 2 terms of 4 followed by 3 and 4, then 4 terms of 6 followed by 5 and 6, etc. In other words, a(n*(3+n)) = 2n+1 and for the rest of the terms, a(n*(n+1)) ,..., a(n+(n+1)^2) = 2*(n+1). It can be shown that this definition satisfies the recurrence relation. - _Chai Wah Wu_, Jun 06 2016

V3-006355 | OEIS-A194469

Values of m for which sqrt(m) is curbed by 1/2; see Comments for "curbed by".

Suppose that r and c are real numbers, that 0<c<1, and that s(n)=sum{<c+k*r>-<k*r> : 1<=k<=n}, where < > denotes fractional part. The inequalities s(n)<0, s(n)=0, s(n)>0 yield up to three sequences that partition the set of positive integers, as in the examples cited at A194368. If s(n)>=0 for every n>=1, we say that r is curbed by c. For r=sqrt(m), clearly r is curbed by 1/2 if m is a square. Conjecture: there are infinitely many nonsquare m for which sqrt(m) is curbed by 1/2, and there are infinitely many m for which sqrt(m) is not curbed by 1/2 (see A194470). The terms shown here for A194469 are conjectured, based on examinations of s(n) for 1<=n<=B for various B>100.

V3-006361 | OEIS-A194688

First differences of A036554 (numbers whose binary representation ends in an odd number of zeros).

Conjecture. This sequence is self-generated according to the following rule: start with {4} at step 0, then extend by steps, appending {2,2,4} at step n if a(n)=4 or appending {4} if a(n)=2. (This has been verified for several thousand terms.) To illustrate, the first few steps of this process give {4}->{4,2,2,4}, since a(1)=4, ->{4,2,2,4,4}, since a(2)=2, ->{4,2,2,4,4,4}, since a(3)=2, ->{4,2,2,4,4,4,2,2,4}, since

a(4)=4, etc. Equivalently, it appears that {a(n)} is the fixed-point of the morphism 2->4, 4->422, starting with 4. Since A036554 = 2*A003159, this conjecture follows from the paper by Allouche, Shallit and Skordev in 2005, see page 13. - _Michel Dekking_, Jan 06 2019

V3-006381 | OEIS-A195264

Iterate x -> A080670(x) (replace x with the concatenation of the primes and exponents in its prime factorization) starting at n until reach 1 or a prime (which is then the value of a(n)); or a(n) = -1 if a prime is never reached.

J. H. Conway offered $1000 for a proof or disproof for his conjecture that every number eventually reaches a 1 or a prime - see OEIS50 link. - _N. J. A. Sloane_, Oct 15 2014 The number D' = 13^532385396179 maps to D and so is a much larger number with a(D') = -1. Repeating this process (by finding a prime prefix of D') should lead to an infinite sequence of counterexamples to Conway's conjecture. - _Hans Havermann_, Jun 09 2017

猜想/问题提及段 | historical_or_current_mention_unreviewed | _N. J. A. Sloane_, Sep 14 2011, based on discussions on the Sequence Fans Mailing List by _Alonso del Arte_, _Franklin T. Adams-Watters_, _D. S. McNeil_, _Charles R Greathouse IV_, _Sean A. Irvine_, and others | 2026-10-24

V3-006408 | OEIS-A195871

a(n) is the smallest prime(m) such that the interval (prime(m)*n, prime(m+1)*n) contains exactly one prime.

Conjecture: In the supposition that there are infinitely many twin primes, for n>=5 all terms are in A001359 (lesser of twin primes). Note that a unique prime which is contained in an interval of the form (prime(m)*n, prime(m+1)*n) is called n-isolated (see author's link, where a heuristic proof is given that the number of n-isolated primes<=x approaches e^{-2(n-1)}x/log(x) as x goes to infinity (cf. Conjecture 25, Remark 26 and formula (47)). One can easily prove that a(n) is not bounded. This conjecture seems hard, since it's not obvious how to find an upper bound for a(n) (see Conjecture 42 in the Shevelev link). - _Charles R Greathouse IV_, Jan 02 2013

V3-006416 | OEIS-A196226

m such that A054024(m) (sum of divisors of m reduced modulo m) is 3 + m/2.

Conjectures. (1) If m>=14 is a term of this sequence, then sigma(2,m) is congruent to 5 + m/2 modulo m; (2) If m>=22 is a term of this sequence, then sigma(3,m) is congruent to 9 + m/2 modulo m; If m>=38 is a term of this sequence, then sigma(4,m) is congruent to 17 + m/2 modulo m. (sigma(k,m) denotes the sum of the k-th powers of the divisors of m.) Similar conjectures can be made about sigma(k,m) congruent to 2^k+1 + m/2 modulo m, for m a sufficiently large term of this sequence..

V3-006418 | OEIS-A196523

G.f. A(x) satisfies A(x) = x + x*A(A(A(A(x)))).

Conjecture: a(n) == 1 (mod 3) for n >= 1. - _Paul D. Hanna_, Dec 01 2024 The conjecture is true, and more generally if A(x) = x + x*A^[l](x), where A^[l] is the l-th iterate of A, then a(n) == 1 (mod l-1) for n >= 1. Proof: the equation determines a(n) from a(1..n-1) by integer polynomial recurrences, so A mod l-1 is the unique solution over Z/(l-1). Let B(x) = x/(1-x); by induction B^[k](x) = x/(1-k*x). Since l == 1 (mod l-1), B^[l] = B, and x + x*B = x/(1-x) = B. Hence A == x/(1-x) (mod l-1). - _Amol Bhave_, Oct 13 2026

V3-006456 | OEIS-A198636

One half of total number of round trips, each of length 2n, on the graph P_6 (o-o-o-o-o-o).

Conjecture: a(n) = 2^(2*n)*(sum_{k=1,2,3} (cos(k*Pi/7))^(2*n)). - _L. Edson Jeffery_, Jan 21 2012 (in fact this conjecture was recently proved in [Barbero, et al.]) Let r,s,t be the roots of x^3 + x^2 - 2x - 1; then apparently a(n) = r^(2n) + s^(2n) + t^(2n). - _James R. Buddenhagen_, Nov 03 2013 [This is equivalent to the conjecture by _L. Edson Jeffery_.]

V3-006499 | OEIS-A200503

Record (maximal) gaps between prime sextuplets (p, p+4, p+6, p+10, p+12, p+16).

Prime sextuplets (p, p+4, p+6, p+10, p+12, p+16) are densest permissible constellations of 6 primes. Average gaps between sextuplets (and, more generally, between prime k-tuples) can be deduced from the Hardy-Littlewood k-tuple conjecture and are O(log^6(p)). Maximal gaps may be significantly larger than average gaps; this sequence suggests that maximal gaps are O(log^7(p)). (1) Conjectured upper bound: gaps between prime sextuplets (p, p+4, p+6, p+10, p+12, p+16) are smaller than 0.058*(log p)^7, where p is the prime at the end of the gap. (2) Estimate for the actual size of the maximal gap that ends at p: maximal gap = a(log(p/a)-1/3), where a = 0.058*(log p)^6 is the average gap between sextuplets near p, as predicted by the Hardy-Littlewood k-tuple conjecture. Formulas (1) and (2) are asymptotically equal as p tends to infinity. However, (1) yields values greater than all known gaps, while (2) yields "good guesses" that may be either above or below the actual size of maximal gaps. Both formulas (1) and (2) are derived from the Hardy-Littlewood k-tuple conjecture via probability-based heuristics relating the expected maximal gap size to the average gap. Neither of the formulas has a rigorous proof (the k-tuple conjecture itself has no formal proof either). In both formulas, the constant ~0.058 is reciprocal to the Hardy-Littlewood 6-tuple constant 17.2986...

V3-006500 | OEIS-A200526

a(n) = gcd(t(n), t(3n-1)), where t = A200217.

Successive maxima of the GCD in A200217 occur between A200217(n) and A200217(3n-1) terms. Conjecture: All terms have same set of prime divisors, that can be used to complete prime factorization of every term in this sequence by the GCD method. All prime divisors with exception 19 are of the form 4k+1. The integer 19 divides a(3n+1) for n=0,1,2,3,...

V3-006535 | OEIS-A201051

Record (maximal) gaps between prime septuplets (p, p+2, p+6, p+8, p+12, p+18, p+20).

Prime septuplets (p, p+2, p+6, p+8, p+12, p+18, p+20) are one of the two types of densest permissible constellations of 7 primes (A022009 and A022010). Average gaps between prime k-tuples can be deduced from the Hardy-Littlewood k-tuple conjecture and are O(log^k(p)), with k=7 for septuplets. If a gap is larger than any preceding gap, we call it a maximal gap, or a record gap. Maximal gaps may be significantly larger than average gaps; this sequence suggests that maximal gaps are O(log^8(p)).

V3-006538 | OEIS-A201062

Record (maximal) gaps between prime 5-tuples (p, p+4, p+6, p+10, p+12).

Prime quintuplets (p, p+4, p+6, p+10, p+12) are one of the two types of densest permissible constellations of 5 primes (A022006 and A022007). Average gaps between prime k-tuples can be deduced from the Hardy-Littlewood k-tuple conjecture and are O(log^k(p)), with k=5 for quintuplets. If a gap is larger than all preceding gaps, we call it a maximal gap, or a record gap. Maximal gaps may be significantly larger than average gaps; this sequence suggests that maximal gaps between quintuplets are O(log^6(p)). (2) Estimate for the actual size of the maximal gap that ends at p: maximal gap ~ a(log(p/a)-0.4), where a = 0.0987*(log p)^5 is the average gap between quintuplets near p, as predicted by the Hardy-Littlewood k-tuple conjecture. Both formulas (1) and (2) are derived from the Hardy-Littlewood k-tuple conjecture via probability-based heuristics relating the expected maximal gap size to the average gap. Neither of the formulas has a rigorous proof (the k-tuple conjecture itself has no formal proof either). In both formulas, the constant ~0.0987 is reciprocal to the Hardy-Littlewood 5-tuple constant 10.1317...

V3-006539 | OEIS-A201073

Record (maximal) gaps between prime 5-tuples (p, p+2, p+6, p+8, p+12).

Prime quintuplets (p, p+2, p+6, p+8, p+12) are one of the two types of densest permissible constellations of 5 primes (A022006 and A022007). Average gaps between prime k-tuples can be deduced from the Hardy-Littlewood k-tuple conjecture and are O(log^k(p)), with k=5 for quintuplets. If a gap is larger than any preceding gap, we call it a maximal gap, or a record gap. Maximal gaps may be significantly larger than average gaps; this sequence suggests that maximal gaps are O(log^6(p)). (2) Estimate for the actual size of the maximal gap that ends at p: maximal gap ~ a(log(p/a)-0.4), where a = 0.0987*(log p)^5 is the average gap between quintuplets near p, as predicted by the Hardy-Littlewood k-tuple conjecture. Both formulas (1) and (2) are derived from the Hardy-Littlewood k-tuple conjecture via probability-based heuristics relating the expected maximal gap size to the average gap. V3-006541 | OEIS-A201202

Row sums of triangle A201201: first associated monic Laguerre polynomials with parameter alpha=1 evaluated at x=1.

This e.g.f. satisfies the homogeneous second-order differential equation: (1+x)^2*(d^2/dx^2)g(x) + (5+6*x)*(d/dx)g(x) + 6*g(x) = 0, with g(0)=1 and (d/dx)g(x)|_{x=0} = -3. This is equivalent to the recurrence conjectured by _R. J. Mathar_, which is thus proved.

V3-006569 | OEIS-A201828

The smallest A(m) such that the interval (A(m)*n, A(m+1)*n) contains exactly one element of A, where A is the sequence of primes p for which p-2 is not prime.

This is a possible model sequence to understand the role of twin primes in sequences like A195871. In particular, if after a large number N_tw, there are no twin primes, what primes will take their place in A195871? Our observations and expectations are expressed in the following conjecture. Conjecture: For n>=13, every a(n) is the lesser of a pair of cousin primes p and p+4, cf. A023200. Note that it is only conjectured that there are infinitely many pairs of cousin primes.

V3-006581 | OEIS-A202056

Smallest d such that Mordell's elliptic curve x^3-y^2=d (for positive d) has an integral point in the quadratic extension sqrt(A202057(n)).

The existence of such d for each A202057(n) is conjectural following the conjecture in A201278.

V3-006587 | OEIS-A202150

a(n) = A202146(3*n*(n+1)) for n>=0.

Conjecture: this sequence consists of all odd terms in A202146; the g.f. of A202146 is 1/(1-x) + Sum_{n>=1} x^n/(1-x) * Product_{k=1..n} (1 - x^k) / (1 - x^(2*k+1)), which by the conjecture has an odd coefficient of x^m iff m = 3*n*(n+1) for n>=0. The conjecture holds for at least the initial 30300 terms of A202146.

V3-006594 | OEIS-A202281

Record (maximal) gaps between prime decuplets (p+0,2,6,8,12,18,20,26,30,32).

Average gaps between prime k-tuples are O(log^k(p)), with k=10 for decuplets, by the Hardy-Littlewood k-tuple conjecture. If a gap is larger than any preceding gap, we call it a maximal gap, or a record gap. Maximal gaps may be significantly larger than average gaps; this sequence suggests that maximal gaps are O(log^11(p)). Both formulas (1) and (2) are derived from the Hardy-Littlewood k-tuple conjecture via probability-based heuristics relating the expected maximal gap size to the average gap. Neither of the formulas has a rigorous proof.

V3-006595 | OEIS-A202319

Lesser of two semiprimes sandwiched each between semiprimes thus forming a twin semiprime-triple.

Conjecture: For every natural number k there are infinitely many semiprime pairs sp and sp' both sandwiched between semiprimes such that sp' - sp = 4k. The number centered between the triples of a twin semiprime-triple must be divisible by 36. Let m be the middle of such a twin semiprime-triple. It is trivial that m is divisible by 4, and that it is congruent to 0, 4, or 5 (mod 9). If it were congruent to 4, then m-1 and m+2 would both be divisible by 3, hence equal to 3 times a prime. But then those two primes would differ by 1, impossible except for primes 2, 3, which can be checked separately. A similar argument eliminates the case m == 5 (mod 9), so m must be divisible by 9. Conjecture by the author, proved by _Franklin T. Adams-Watters_, Dec 18 2011.

V3-006625 | OEIS-A202917

For n >= 0, let n!^(1) = A053657(n+1) and, for 0 <= m <= n, C^(1)(n,m) = n!^(1)/(m!^(1)*(n-m)!^(1)). The sequence gives a triangle of numbers C^(1)(n,m) with rows of length n+1.

3) If p is an odd prime, then the (p-1)-th row contains two 1's and p-2 numbers that are multiples of p. For a conjectural generalization, see comment in A175669.

V3-006658 | OEIS-A203399

T(n, k), a triangular array read by rows, is the number of classes of equivalent 2-color n-bead necklaces (turning over is allowed) that contain k necklaces.

Conjectures: For n >= 1, let b(n) be the number of bracelets of two colors with n beads that are either periodic (period >= 2), or have reflection symmetry (achiral), or both. Then b(n) = A000029(n) - A032239(n) for n >= 3 with b(n) = A000029(n) for n = 1, 2. We have A000029(n) = 2^floor(-3 + n/2) * (7 - (-1)^n) + (1/(2*n)) * Sum_{d|n} phi(d) * 2^(n/d) for n >= 1 and A032239(n) = (1/2) * Sum_{d|n} mu(d) * (-2^floor(-2 + (n/(2*d))) * (7 - (-1)^(n/d)) + 2^(n/d)/n) for n >= 3. For 1 <= k <= n, we conjecture that T(n, k) = Sum_{d|k} mu(d)*b(k/d) for k|n, and = 0 otherwise. Note that, if 3 <= n <= 11, we have T(n, k) = A056493(k) when k|n, but this is not true (for example) for n = 12 and n = 14. We have T(12, 12) = 82 <> 81 = A056493(12) and T(14, 14) = 177 <> 175 = A056493(14). I ran the author's Mathematica program for n = 1..21 and I saw that the conjecture is OK except for n = 18 and n = 21. The program gives T(n=18, k=12) = 1 and T(n=18, k=18) = 742 while my conjecture implies that T(n=18, k=12) = 0 (since k = 12 does not divide n = 18) and T(n=18, k=18) = 743. In addition, the program gives T(n=21, k=14) = 2 and T(n=21, k=21) = 2030, while my conjecture implies that T(n=21, k=14) = 0 (since k = 14 does not divide n = 21) and

T(n=21, k=21) = 2032. Apparently, my conjecture needs to be refined.

V3-006710 | OEIS-A204844

Cyclic primes that are not absolute primes (A003459).

Conjecture: The sequence is finite, with 999331 being the last term (cf. A293142). - _Felix Fröhlich_, Aug 05 2018

猜想/问题提及段 | historical_or_current_mention_unreviewed | _N. J. A. Sloane_, Jan 19 2012 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006711 | OEIS-A204983

a(n) = 2^(k-1)-2^(j-1), where (2^(k-1),2^(j-1)) is the least pair of distinct positive powers of 2 for which n divides 2^(k-1)-2^(j-1).

(Conjecture) Equivalently, the solution set of 2^p * (2^q - 1) = x * y, OR 2^q - 1 = 2^p * x * y, for at most one of the naturals x and y being given; unknown p and q in the integers; then a(n) = 2^p * (2^q - 1) where p and q are directly related to n (see formula). - _Andrew T. Porter_, Dec 20 2022 Conjecture: a(n) = 2^A007814(n) * (2^A007733(n) - 1). - _Andrew T. Porter_, Dec 20 2022

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Clark Kimberling_, Jan 21 2012 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006712 | OEIS-A204988

The index j < k such that n divides 2^k - 2^j, where k is the least index (A204987) for which such j exists.

a(n) = A007814(n) + (1-(-1)^n)/2 (conjecture). - _Velin Yanev_, Nov 14 2016. The above conjecture is true because the definition of this sequence and A204987 requires j to be at least 1 and 2^k - 2^j can be written 2^j*(2^(k-j) - 1).

V3-006727 | OEIS-A205497

Triangle read by rows: Zig-zag Eulerian number triangle T(n, k).

(Previous name:) Omitting the first two ones, a rectangular array M read by antidiagonals in which entry M_{n-k, k} in row n-k and column k, 0 <= k <= n, gives the coefficient of x^k in the numerator of the conjectured generating function for row n + 3 of the tabular form of A050446. Conjecture: 1. M_{n, k} = M_{k, n}, for all n and k; that is, M is symmetric about the central terms {1, 3, 31, 623,...}. (This has been verified for the first 100 antidiagonals of M.) Conjecture: 2. For m in {3, 4,...}, row m of array A050446 has generating function of the form H_m(x)/(1 - x)^m, in which the numerator H_m(x) is a polynomial of degree m - 3 in x with coefficients given by the entries of the (m - 3)-th antidiagonal of M containing the sequence of entries {M_{m-3-j,j}}, j=0..m-3 (see the example below). It is known that H_1(x) = H_2(x) = 1. Conjecture: 3. Define the Chebyshev polynomials of the second kind by U_0(t) = 1, U_1(t) = 2*t and U_r(t) = 2*t*U_(r-1)(t) - U_(r-2)(t) (r > 1). Assuming Conjecture 1, lim_{n -> infinity} M_{n+1, k}/M_{n, k} = U_k(cos(Pi/(2*k+3))) = spectral radius of the (k+1) X (k+1) unit-primitive matrix (see [Jeffery]) A_{2*k+3, k} = [0,...,0,1; 0,...,0,1,1; ...; 0,1,...,1; 1,...,1], with identical limits for the columns of the transpose M^T of M. Conjecture: 4. Let S(u, v) denote the entry in row u and column v of triangle S = A187660, 0 <= v <= u. Define the polynomials P_u(x) = Sum[S(u, v)*x^v]. Assuming Conjecture 1, then (i) the generating function for row (or column) n of M is of the form Remarks: The coefficients in the numerators G_n(x) appear to have no pattern. The polynomial P_j(x), j in {1,...,n+1}, of Conjecture 4 is also obtained from the characteristic polynomial of the unit-primitive matrix A_{2*j+3,j} of Conjecture 3 by taking the exponents of the latter in reverse order; and P_j(x) is otherwise identical to the characteristic polynomial of the unit-primitive matrix A_{2*j+3,1}. Conjecture: The Eulerian zig-zag polynomials have only negative and simple real roots and form a Sturm sequence, that is, p(n+1, x) has n real roots separated by the roots of p(n, x). This property was proved by Frobenius for the classical Eulerian polynomials. - _Peter Luschny_, Jun 04 2024 Conjecture: 5.1. G.f. for column 0 of M is 1/(1-x) (A000012). Conjecture: 5.2. G.f. for column 1 of M is 1/((1-x)^2*(1-x-x^2)) (A001924). Conjecture: 5.3. G.f. for column 2 of M is (1 - x^2 - x^3 - x^4 + x^5)/((1-x)^3*(1-x-x^2)^2*(1 - 2*x - x^2 + x^3)) (A205492). Conjecture: 5.4. G.f. for column 3 of M is (1 + x - 6*x^2 - 15*x^3 + 21*x^4 + 35*x^5 - 13*x^6 - 51*x^7 + 3*x^8 + 21*x^9 + 5*x^10 + x^11 - 5*x^12 - x^13 - x^14)/((1-x)^4*(1-x-x^2)^3*(1 - 2*x - x^2 + x^3)^2*(1 - 2*x - 3*x^2 + x^3 + x^4)) (A205493). Conjecture: 5.5. G.f. for column 4 of M is (1 + 4*x - 31*x^2 - 67*x^3 + 348*x^4 + 418*x^5 - 1893*x^6 - 1084*x^7 + 4326*x^8 + 4295*x^9 - 7680*x^10 - 9172*x^11 + 9104*x^12 + 11627*x^13 - 5483*x^14 - 10773*x^15 + 1108*x^16 + 7255*x^17 + 315*x^18 - 3085*x^19 - 228*x^20 + 669*x^21 + 102*x^22 - 23*x^23 - 45*x^24 - 16*x^25 + 11*x^26 + 2*x^27 - x^28)/((1-x)^5*(1-x-x^2)^4*(1 - 2*x - x^2 + x^3)^3*(1 - 2*x - 3*x^2 + x^3 + x^4)^2*(1 - 3*x - 3*x^2 + 4*x^3 + x^4 - x^5)) (A205494).

V3-006786 | OEIS-A207375

Irregular array read by rows in which row n lists the (one or two) central divisors of n in increasing order.

Conjecture 1: It appears that the n-th record in this sequence is the last member of row A008578(n). The conjecture 1 follows from Bertrand's Postulate. - _Charles R Greathouse IV_, Feb 11 2022

V3-006787 | OEIS-A207384

A206815(n+1)-A206815(n).

The sequences A206815, A206818, A207384, A207835 illustrate the closeness of {j+pi(j)} to {k+(k+1)/log(k+1)}, as suggested by the prime number theorem and the conjecture that all the terms of A207384 and A207835 are in the set {1,2,3}.

V3-006836 | OEIS-A208229

Consider Wolfram's universal 2-state 3-symbol Turing machine on a one-way-infinite tape with all but the first n cells initially blank and the head initially in state 1. a(n) is the maximum number of steps the Turing machine can make before halting.

For initial conditions with n<=11, the machine always halts (the Mathematica code given assumes that the machine halts for all finite configurations). Whether this remains true is an open question.

V3-006847 | OEIS-A208296

Smallest positive nontrivial odd solution of the congruence x^2 == 1 (mod A001748(n+2)), n >= 1.

a(n) solves also the congruence x^2 == 1 (Modd A001748(n+2)), n>=1. For Modd n (not to be confused with mod n) see a comment on A203571. This follows from floor(a(n)^2/3*prime(n+2)) being even, in fact it is 8*A024699(n) (see a comment there), hence a(n)^2 (Modd 3*prime(n+2)) = a(n)^2 (mod 3*prime(n+2)) = 1. For those multiplicative groups Modd 3*p with p an odd prime which are cyclic (this is not possible in the mod case, see A033949), a(n) is the representative of the only other nontrivial solution of this congruence. The representative of the trivial solution is 1 (-1 belongs to the same Modd class). (The conjecture stated here earlier is wrong, that is, the multiplicative group Modd (91=7*13) is non-cyclic. It may still be true for 3*p. - _Wolfdieter Lang_, Mar 15 2012)

V3-006864 | OEIS-A208494

Least integer m>1 such that those k! mod m with k=1,...,n are pairwise distinct.

On Feb 27 2012 Zhi-Wei Sun conjectured that a(n) is a prime with the only exception a(5)=10, and that a(n) does not exceed n^2/2 for all n=2,3,4,... He also conjectured that max{n>0: 1!,...,n! are pairwise incongruent mod p} is asymptotically equivalent to sqrt(p), where p is an odd prime. He guessed that if we replace k! in the definition of a(n) by (-1)^k*k! then a(n) is a prime with the only exception a(3)=6. If we replace k! in the definition of a(n) by (2k)! or (-1)^k*(2k)!, then Zhi-Wei Sun conjectured that a(n) will take only prime values. He also has similar conjectures involving (r*k)! or (-1)^k*(r*k)! with r>2.

V3-006904 | OEIS-A209260

Irregular triangular array read by rows, resulting in a permutation of the natural numbers.

Conjecture 1. 2*n+1 is in the set S_n = {union of first n rows of A209260} if and only if 2*n+1 is composite. (Verified for all n <= 10^6 by _Charles R Greathouse IV_.) This conjecture has been proved (see [Jeffery]). Conjecture 2. Let N be an integer, N>0, and let D_N be the set of all positive integral divisors of N. Let B_N be the set of all integral solutions of d + (h-1)/2 for which d in D_N, with h=N/d and N=d*h (some solutions will not be integers and so are not in B_N). Then N appears in row r = min(B_N) of A209260. Also, N appears in row b of A141419, for each b in B_N. - _L. Edson Jeffery_, Feb 13 2013 For a proof of Conjecture 2 see the link.

V3-006930 | OEIS-A209934

a(n) is the first value to occur consecutively in the sequence b_n defined by p_2k(b_n(k)) = p_k(n)^2, k=1,2,3,..., where p_k(n) is the n-th k-almost prime.

Conjecture: Each sequence b_n repeats indefinitely. (Example: for n=3, b_n = 9, 8, 8, 8, 8, 8, ... It looks like b_3(k) is 8 for all k > 1.) The conjecture follows from the formula that uses A078843 below (and the strict monotonicity of A078843). However the first repeated value is not for every n the value that repeats indefinitely. For example a(8) = b_8(2) = b_8(3) = 66, but b_8(k) = 64 for k >= 4. - _Peter Munn_, Aug 05 2019

V3-006952 | OEIS-A210468

Collatz (3x+1) problem with rational numbers: number of steps to reach the end of the cycle starting with 1/(2n+1).

This variation of the "3x+1" problem with a class of rational numbers is as follows: start with any number 1/(2n+1). If the numerator is even, divide it by 2, otherwise multiply it by 3 and add 1. Do we always reach the end of a cycle with a rational number? It is conjectured that the answer is yes. If x is of the form x = m/(2n+1) where m is an integer, it is conjectured that the number of steps tends into the end of a finite cycle.

V3-006960 | OEIS-A210528

Number of ways to write 2n = p+q (p<=q) with p, q and p^6+q^6 all practical.

Conjecture: a(n)>0 for all n>0. Moreover, for any positive integers m and n, if m is greater than one or n is not among 17, 181, 211, 251, 313, 337, then 2n can be written as p+q with p, q and p^{3m}+q^{3m} all practical. This conjecture implies that for each m=1,2,3,... there are infinitely many practical numbers of the form p^{3m}+q^{3m} with p and q both practical.

V3-006975 | OEIS-A211175

Triangle read by rows: row n gives, in increasing order, the prime divisors of all the composites of the form k^2 + 1 between the two primes A002496(n) and A002496(n+1).

A variety of conjecturally infinite subsequences and starting with {2, 5, ...} can be shown in the graph of the sequence. If the number of primes of the form n^2 + 1 is finite, then the last subsubsequence of the graph abruptly becomes A002144(n) union {2} (odd Pythagorean primes with the number 2). In this case, the discontinued forms of the graph disappear. But this case is highly improbable.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Michel Lagneau_, Feb 01 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-006976 | OEIS-A211189

Number of prime divisors formed by {2} and the consecutive Pythagorean primes for all the composites k^2 + 1 between the two primes A002496(n) and A002496(n+1).

These considerations confirm the opinion of the truthfulness of the conjecture about an infinity of primes of the form n^2 + 1. This sequence gives the length of a variety of conjecturally infinite subsequences of consecutive primes starting with {2, 5, ...}. If the number of primes of the form n^2 + 1 were finite, there should exist a last prime p such that this sequence stops abruptly from p because the length of A002144(n) is infinite. In this case, we should observe a contradictory behavior of this sequence between the stability of the slow growth of a(n) and the discontinuity from the prime p. But this case is highly improbable.

V3-006992 | OEIS-A211433

Number of ordered triples (w,x,y) with all terms in {-n,...,0,...,n} and w+2x+4y=0.

Also, a(n) is the number of ordered pairs (w,x) with both terms in {-n,...,0,...,n} and w+2x divisible by 4. If (w,x) is such a pair it is easy to see that (-w,x), (-w,-x), and (w,-x) also are such pairs. The number of pairs with both w and x positive is given by A211521(n). If w=0, x must be even, and if x=0, w must be divisible by 4. This means that a(n) = 4*A211521(n) + 2*floor(n/2) + 2*floor(n/4) + 1. Since the sequences A211521(n), floor(n/2), floor(n/4), and the constant sequence all satisfy the recurrence conjectured in the formula section, a(n) must also satisfy the recurrence, so this proves the conjecture. - _Pontus von Brömssen_, Jan 19 2020 Conjectures from _Colin Barker_, May 15 2017: (Start)

V3-006993 | OEIS-A211434

Number of ordered triples (w,x,y) with all terms in {-n,...,0,...,n} and w+2x+5y=0.

Also, a(n) is the number of ordered pairs (w,x) with both terms in {-n,...,0,...,n} and w+2x divisible by 5. If (w,x) is such a pair it is easy to see that (-x,w), (-w,-x), and (x,-w) also are such pairs. If both w and x are nonzero these four pairs lie one in each quadrant. If one of w or x is zero, the other must be a multiple of 5. This means that a(n) equals 4*A211523(n) (the nonzero pairs) plus 4*floor(n/5) + 1 (pairs with w or x equal to zero). Since the sequences A211523(n), floor(n/5), and the constant sequence all satisfy the recurrence conjectured in the formula section, a(n) must also satisfy the recurrence, so this proves the conjecture. - _Pontus von Brömssen_, Jan 17 2020 Conjectures from _Colin Barker_, May 15 2017: (Start)

V3-007028 | OEIS-A212198

Leading diagonal of triangle in A211321.

Conjectured to be the number of permutations of length n avoiding the partially ordered pattern (POP) {1>5, 2>5, 5>3, 5>4} of length 5. That is, conjectured to be the number of length n permutations having no subsequences of length 5 in which the fifth element is larger than the elements in positions 3 and 4, but smaller than the elements in positions 1 and 2. - _Sergey Kitaev_, Dec 13 2020 The conjecture of Kitaev has been proven. It can be restated as the number of size n permutations avoiding 45123, 45213, 54123, 54213. There are nineteen sets of permutations avoiding four size five permutations that are known to match this sequence. A further four are conjectured to match this sequence. - _Christian Bean_, Jul 23 2024

V3-007056 | OEIS-A212814

a(n) = number of integers k >= 7 such that A212813(k) = n.

Comment from Hans Havermann, Sequence Fans Mailing List, May 31 2012: The 11 numbers k for which A212813(k)=2 are 9, 11, 14, 20, 24, 27, 28, 40, 45, 48, 54. Empirically, it appears that 2632 is the sum of the number of prime partitions (A000607) of the eleven numbers 8, 10, 13, 19, 23, 26, 27, 39, 44, 47, 53. I hesitate turning this into a conjecture only because the 3 numbers k for which A212813(k)=1 are 7, 10, 12 and the sum of the number of prime partitions of the three numbers 6, 9, 11 is twelve, not eleven (the extra partition being, I think, 2+2+2).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _N. J. A. Sloane_, May 30 2012. I added _Hans Havermann_'s comment May 31 2012 | 2026-10-24

V3-007063 | OEIS-A212843

Carmichael numbers that have only prime divisors of the form 10k+1.

Conjecture: only Carmichael numbers of the form 10n+1 can have prime divisors of the form 10k+1 (but not all Carmichael numbers of the form 10n+1 have prime divisors of the form 10k+1). Conjecture: all Carmichael numbers C (not only with three prime divisors) of the form 10n+1 that have only prime divisors of the form 10k+1 can be written as C = (30a+1)*(30b+1)*(30c+1), C = (30a+11)*(30b+11)*(30c+11), or C = (30a+1)*(30b+11)*(30c+11). In other words, there are no numbers of the form C = (30a+1)*(30b+1)*(30c+11). The first conjecture is a consequence of Korselt's criterion. - _Charles R Greathouse IV_, Oct 02 2012

V3-007064 | OEIS-A212855

T(n,k) = number of n X k arrays with rows being permutations of 0..k-1 and no column j greater than column j-1 in all rows (n, k >= 1).

The integer partitions of k = 1..10 are listed on pp. 831-832 of Abramowitz and Stegun (1964). We see that, for k = 1..6, the corresponding multinomial coefficients k! / ((1!)^a_1 * (2!)^a_2 * ... * (k!)^a_k) are all distinct; that is, A070289(k) = A000041(k) and A309951(k,s) = A325305(k,s) for s = 0..A000041(k). For 7 <= k <= 10, this is not true anymore; i.e., A070289(k) < A000041(k) for 7 <= k <= 10 (and we conjecture that this is the case for all k >= 7).

V3-007079 | OEIS-A213257

a(1) = 1, a(2) = 2 and, for n > 2, a(n) is the smallest integer greater than a(n - 1) such that no three terms of the sequence form a geometric progression of the form {x, 2 x, 4 x}.

Conjecture. The positive integers that are not in this sequence are given by the positions of 2 in the fixed-point of the morphism 0->01, 1->02, 2->03, 3->01 (see A191255). (This has been confirmed for over 5000 terms of A213257.) To illustrate, the fixed-point of the indicated morphism is {0,1,0,2,0,1,0,3,0,1,0,2,0,1,0,1,0,1,0,2,0,...} and 2 occurs at positions {4,12,20,...}, integers that are missing in A213257.

V3-007080 | OEIS-A213258

Positive integers that are not in A213257.

Conjecture. The terms of this sequence are given by the positions of 2 in the fixed-point of the morphism 0 -> 01, 1 -> 02, 2 -> 03, 3 -> 01 (see A191255). (This has been confirmed for over 5000 terms of A213257.) To illustrate, the fixed-point of the indicated morphism is {0,1,0,2,0,1,0,3,0,1,0,2,0,1,0,1,0,1,0,2,0,...} and 2 occurs at positions {4,12,20,...}, integers in this sequence but missing from A213257. The above two conjectures are correct. This is indeed positions of 2 in A191255, and numbers of the form 2^(3t+2)*s where s is an odd number. - _Jianing Song_, Sep 21 2018

V3-007083 | OEIS-A213381

a(n) = n^n mod (n+2).

Conjectures: Conjecture 1) is true: with m = n+2, a(n) = (-2)^(m-2) mod m = 0 iff m divides 2^(m-2), i.e., m = 2^k for some k with k <= m-2 (which is true for k >= 2). Conjecture 2) is true: if n = 3*p-2 where p is prime, then n == 1 (mod 3) so n^n == n (mod 3), and n^(p-1) == 1 (mod p) so n^n == n (mod p), and therefore (if p <> 3) n^n == n (mod 3*p). A separate computation verifies the case p=3.

V3-007094 | OEIS-A213648

The minimum number of 1's in the relation n*[n,1,1,...,1,n] = [x,...,x] between simple continued fractions.

Conjecture: the fixed points of this sequence are in A000057. The conjecture above is true; in fact, the fixed points of this sequence are exactly the terms of A000057. See Formula. - _M. Jeremie Lafitte (Levitas)_, Aug 10 2026 Conjecture: a(n)=A001177(n)-1. The conjecture is true. For n>=2, write F(k)=A000045(k) and M(t)={{t,1},{1,0}}. If [n,1,...,1,n] contains m occurrences of 1, then M(n) M(1)^m M(n)={{P,Q},{Q,F(m+1)}}, where P F(m+1)-Q^2=(-1)^m. Applying the Euclidean algorithm to this symmetric continuant matrix, with the canonical convention that the final partial quotient is greater than 1, shows that the canonical simple continued fraction obtained by multiplying [n,1,...,1,n] by n has equal first and last partial quotients if and only if n | F(m+1). Hence a(n)=min{m>=1: n | F(m+1)}=A001177(n)-1. This proves Art DuPre's 2012 conjecture.

V3-007100 | OEIS-A213892

Fixed points of a sequence h(n) defined by the minimum number of 3's in the relation n*[n,3,3,...,3,n] = [x,...,x] between simple continued fractions.

We conjecture that this sequence contains prime numbers analogous to the sequence of prime numbers A000057, in the sense that, instead of referring to the Fibonacci sequences (sequences satisfying f(n) = f(n-1) + f(n-2) with arbitrary positive integer values for f(1) and f(2)) it refers to the sequences satisfying f(n) = 3*f(n-1) + f(n-2), A006190, A003688, A052924, etc. This would mean that a prime is in the sequence if and only if it divides some term in each of the sequences satisfying f(n) = 3*f(n-1) + f(n-2). In response to the conjecture above, an exhaustive computation using the rank criterion in the Formula section found no composite term n<=10^6. The proposed characterization of the prime terms by analogy with A000057 is exact, as explained below. For a prime p, these conditions are also equivalent to p dividing a term of every integer sequence satisfying f(k+2)=3*f(k+1)+f(k). Thus the equivalence proposed in the conjecture above holds for primes. (End)

V3-007110 | OEIS-A213982

Least k >= 1 such that prime(n) +- k = 2^m * q, m >= 0, where q >= 2 is prime.

What can one say about the average behavior of a(n) for large n? It is interesting in view of the Broughan-Qizhi inequality A192869(n) >> n*(log(n))^2 and their conjecture that A192869(n) = O(n*(log(n))^2). But in the case of A213982 we have, on average, log(n) possible odd positive and negative values of k with |k| < min(prime(n)-prime(n-1), prime(n+1)-prime(n)) which is approximately log(n). Therefore, we conjecture that, on average, a(n) is approximately c*log(n) with c in (0,1). Calculations up to 10^6 (_Peter J. C. Moses_) show that, most likely, c < 0.298.

V3-007113 | OEIS-A214018

Least k >= 1, such that prime(n) + k has the form 2^m * q, m >= 0, where q >= 2 is prime.

By the definition, a(n)<=p_(n+1)-p_n. It is well known that, for large n, p_(n+1)-p_n on average is approximately log(n). What is the average behavior of a(n)? By the Broughan-Qizhi inequality, A192869(n)>>n*(log(n))^2. Besides, they conjecture that A192869(n)=O(n*(log(n))^2). But in the case of this sequence, we have, on average, log(n)/2 possible odd values of k< p_(n+1)-p_n. Therefore, we conjecture that, on average, a(n) is approximately c*log(n) with c in (0,1). Calculations up to 10^6 (_Peter J. C. Moses_) show that, most likely, c < 0.53 (cf. comment in A213892).

V3-007121 | OEIS-A214305

Fermat pseudoprimes to base 2 with two prime factors.

Conjecture: For any biggest prime factor of a Poulet number p1 with two prime factors, there exists a series with infinitely many Poulet numbers p2 formed this way: p2 mod (p1 - d) = d, where d is the biggest prime factor of p1. Note: it can be seen that the Poulet numbers divisible by 73 bigger than 2701 (7957, 10585, 15841, 31609, etc.) can be written as 1314*n + 73 as well as 2628*m + 73. Conjecture: Any Poulet number p2 divisible by d can be written as (p1 - d)*n + d, where n is a positive integer, if there exists a smaller Poulet number p1 with two prime factors divisible by d. Note: This conjecture can't be extrapolated for Poulet numbers p1 with more than two prime factors; for instance, if p1 = 561 = 3*11*17, there indeed are bigger Poulet numbers divisible by 17 (such as 1105 and 4369) that can be written as 544*n + 17, but there also exist such numbers that can't be written this way, e.g., 2465. But the first conjecture can be extrapolated. Conjecture: For any biggest prime factor of a Poulet number p1 exists a series with infinitely many Poulet numbers p2 formed this way: p2 mod (p1 - d) = d, where d is the biggest prime factor of p1. The conjectured formula p2 = (p1-d)*n+d fails for p1 = 23377 = 97*241, p2 = 34945 = 5*29*241, and d = 241. Here p1 < p2, p1 has exactly two prime factors, and d is its largest prime factor and also divides p2. Both numbers are Poulet numbers. To check this, note that 2^48 == 1 (mod 97) and 2^24 == 1 (mod 241), while both 48 and 24 divide p1-1. Likewise, 2^4 == 1 (mod 5), 2^28 == 1 (mod 29), and 2^24 == 1 (mod 241), while 4, 28, and 24 all divide p2-1. But the proposed formula would require n = (p2-d)/(p1-d) = 34704/23136 = 3/2, which is not an integer. This disproves the representation conjecture, but not the separate infinitude conjectures. - _Eiver Rodríguez_, Sep 22 2026

V3-007156 | OEIS-A214834

a(n) is the smallest prime number such that both a(n) and (4n + 2) - a(n) are prime numbers of the form 4k + 3.

Any even number of the form of 4k + 2 (k > 0) can be partitioned into 4k + 2 = (4i+3) + (4j+3), where i + j + 1 = k. This sequence implies the conjecture that for any number in the form of 4k + 2 (k > 0), there is a partition for which 4i + 3 and 4j + 3 are both prime. Conjecture tested true up to n=1000000000. In case the conjecture is not true, zero could be used to represent the missing entries.

V3-007169 | OEIS-A214971

Integers k for which the base-phi representation of k includes 1.

Conjecture: L(2k-1) and L(2k)+1 are terms of this sequence for all positive integers k, where L=A000032 (Lucas numbers). Proof of this conjecture: this follows directly from the well known formula L(2k)=phi^{2k}+phi^{-2k}, and the recursion L(2k+1)=L(2k)+L(2k-1). - _Michel Dekking_, Jun 25 2019 Conjecture: If D is the difference sequence, then D-3 is the infinite Fibonacci word A096270. If so, then A214971 can be generated as in Program 3 of the Mathematica section. - _Peter J. C. Moses_, Oct 19 2012 Conjecture: A very simple formula for this sequence seems to be a(n) = ceiling((n-1)*phi) + 2*(n-1) for n>1; thus, see the related sequence A004956. - _Thomas Baruchel_, May 14 2018 Moses' conjecture is equivalent to Baruchel's conjecture: Baruchel's conjecture expresses that this sequence is a generalized Beatty sequence, and since A096270 equals the Fibonacci word A005614 with an initial zero, this follows directly from Lemma 8 in Allouche and Dekking. - _Michel Dekking_, May 04 2019 The conjectures by Baruchel and Moses are proved in my paper 'Base phi representations and golden mean beta-expansions'. - _Michel Dekking_, Jun 25 2019

V3-007177 | OEIS-A215056

a(n) = smallest k such that k is both a sum of n nonzero squares and 50-n nonzero squares.

Conjecture: If a vector (x1,...,x50) is a zero to a signature S, then it is only also a zero for S' and no other signature T. {S' is the complement signature of S - all the signs are reversed, so if S=(+,-,-,+,-) then S' is (-,+,+,-,+)}. We therefore modify the conjecture to say that if we define Z_S as the set of integer zeros for S, and Z_t as the collection of integer zeros for all signatures T that are not S or S' (i.e., belong to t), then Z_S is NOT a subset of Z_t. The opposite - for some S, Z_S is a subset of Z_t - implies S has no function. The conjecture is obviously true for k=1, and also for k=1 there are no 'shared zeros'. For k=2, pick one of the 2 squares so that it cannot be equaled by some combination of the other 48 squares, therefore it must be combined with its companion square and so must be a unique integer zero for S(2). For k=3 we require that 2 of the 3 available squares are not matchable, and nor is their sum. This method can be extended for higher k, however the basic existence of such a zero in the first place becomes increasingly less provable.

V3-007194 | OEIS-A215594

Expansion of f(-x, -x^4) / f(x, x^4) in powers of x where f(,) is Ramanujan's two-variable theta function.

Let A(q) denote the g.f. of this sequence. Let m be a nonzero integer. The simple continued fraction expansions of the real numbers A(1/(2*m)) and A(1/(2*m+1)) may be predictable. For a given positive integer n, the sequence of the n-th partial denominators of the continued fractions are conjecturally polynomial or quasi-polynomial in m for m

sufficiently large. An example is given below. Cf. A080054 and A098151. - _Peter Bala_, Jun 10 2025

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-007201 | OEIS-A215692

Smallest prime whose decimal expansion consists of the concatenation of a 1-digit cube, a 2-digit cube, a 3-digit cube, ..., and an n-digit cube, or 0 if there is no such prime.

The n-th term has A000217(n) = n(n+1)/2 digits. We can conjecture that a(n) > 0 for all n > 1 and the terms converge to the concatenation of (c(1), c(2), c(3), ...) where c(k) is the smallest k digit cube, cf. formula. The number of such primes between a(n) and A340115(n) (the largest of this form) is (0, 2, 2, 9, 177, 6909, 570166, ...). (In particular, for n = 2 and 3, a(n) and A340115(n) are the only two primes of this form.) This is very close to what we expect, given the number of concatenations of cubes of the respective length (product of 10^(k/3)-10^((k-1)/3), k=1..n) and the density of primes in that range according to the PNT. - _M. F. Hasler_, Dec 31 2020 a(n) ~ 10^(n(n+1)/2)*0.12712510001064810382310000010077696 1... (conjectured) - _M. F. Hasler_, Dec 31 2020

V3-007232 | OEIS-A216368

Number T(n,k) of distinct values taken by k-th derivative of x^x^...^x (with n x's and parentheses inserted in all possible ways) at x=1; triangle T(n,k), n>=1, 1<=k<=n, read by rows.

Conjecture: T(n,n) = A000081(n) for n>=1. It would be nice to have a proof (or a disproof if the conjecture is wrong).

V3-007233 | OEIS-A216371

Odd primes with one coach: primes p such that A135303((p-1)/2) = 1.

Conjecture relating to odd integers: iff an integer is in the set A216371 and is either of the form 4q - 1 or 4q + 1, (q>0); then the top row of its coach (cf. A003558) is composed of a permutation of the first q odd integers. Examples: 11 is of the form 4q - 1, q = 3; with the top row of its coach [1, 5, 3]. 13 is of the form 4q + 1, q = 3; so has a coach of [1, 3, 5]. 37 is of the form 4q + 1, q = 9; so has a coach with the top row composed of a permutation of the first 9 odd integers: [1, 9, 7, 15, 11, 13, 3, 17, 5]. - _Gary W. Adamson_, Sep 08 2012

V3-007234 | OEIS-A216374

Number of ways to express the square of the n-th prime as the sum of four nonzero squares.

The simple counting and the conjectured first formula agree for all the primes from 3 to 997. The counting and the conjectured second formula agree for all the primes from 5 to 997. The author of this sequence would like to know whether the formulas are already known and/or how it could be proved. a(n) = floor((prime(n)^2 + 4*prime(n) + 24)/48) (conjectured for n>1). a(n) = (prime(n)^2 + 4*prime(n) + (19*(5*(prime(n) mod 48)+2)^2) mod 48 - 24)/48 (conjectured for n>2).

V3-007271 | OEIS-A217475

Coefficients of polynomials in a Melham conjecture.

Coefficients of polynomials in a Melham conjecture. A conjecture by Melham (see the reference, eq. 2.7) is: The table a(m,l) lists the coefficients of these polynomials for m=1..6. Thus the conjecture is certainly true for m=1..6. a(m,l) = [x^l]P(2*m-1,x), m>-1, l=0..2*m-1, with the polynomial P appearing in the Melham conjecture stated in the comment section.

V3-007283 | OEIS-A217772

a(n) = ((p+1)*(3p)!/((2p-1)!*(p+1)!*2p) - 3)/(3p^3), where p is the n-th prime.

This sequence is based on Gary Detlefs's conjecture, which he posted as a comment to A005809. His conjecture is equivalent to the conjecture that the Diophantine equation ((n+1)*(3*n)!/((2*n-1)!*(n+1)!*2*n)-3)/n^3 = m has integer solutions m for all odd primes n. Additionally I conjecture that all m are divisible by 3, therefore terms of this sequence a(n) = m/3. The values of this sequence's terms are replicated by conjectured general formula, given in A223886 (and also added to the formula section here) for k=3, j=1 and n>=2. - _Alexander R. Povolotsky_, Apr 18 2013 a(n) = (binomial(j*k*prime(n), j*prime(n)) - binomial(k*j, j))/(k*prime(n)^3) for k=3, j=1 and n>=2 (conjectured). - _Alexander R. Povolotsky_, Apr 18 2013

V3-007285 | OEIS-A217785

Smallest integer s>n such that 1+2*s+3*s^2+...+n*s^{n-1} is prime.

Conjecture: For each n=2,3,... there are infinitely many primes of the form 1+2*s+...+n*s^{n-1}, where s is a positive integer; moreover, we have a(n)<12*n^2. This is related to the following conjecture of the author: The polynomials s_n(x)=sum_{k=0}^n(k+1)x^k (n=1,2,3,...) are all irreducible over the field of rational numbers; moreover, s_n(x) is reducible modulo every prime if and only if n has the form 8k(k+1), where k is a positive integer.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-007286 | OEIS-A217788

Least integer s > p_n such that sum_{k=1}^n p_k*s^(n-k) (the number [p_1,...,p_n] in base s) is prime, where p_k denotes the k-th prime.

Conjecture: For any integers n >= m > 0, there are infinitely many positive integers s > p_n such that the number sum_{k=m}^n p_k*s^{n-k} (i.e., [p_m,...,p_n] in base s) is prime; moreover the smallest such an integer s (denoted by s(m,n)) does not exceed (n+1)*(m+n+1). A related conjecture of the author states that for each n=2,3,... the polynomial sum_{k=1}^n p_k*x^(n-k) is irreducible modulo some prime. See also the author's comments on A000040. The conjecture can be further extended as follows: If a_1 < ... < a_n are distinct integers with a_n prime, then there are infinitely many integers b > a_n such that [a_1,a_2,...,a_n] in base b is prime. See A224197 for a more general conjecture.

V3-007308 | OEIS-A218465

Least integer b>2n+1 such that the numbers written as [1,3,...,2n-1,2n+1] and [2n+1,2n-1,...,3,1] in base b are both prime.

Conjecture: Let n be any positive integer. Then a(n) exists, moreover there are infinitely many integers b > 2n+1 such that [1,3,...,2n-1,2n+1] and [2n+1,2n-1,...,3,1] in base b are both prime. Also, the polynomial S_n(x) = sum_{k=0}^n (2k+1)*x^{n-k} is irreducible modulo some prime p < (n+1)(n+2), and the Galois group of S_n(x) over the field of rational numbers is isomorphic to the symmetric group S_n. This conjecture can be extended by replacing 2k+1 by (2k+1)^m. For example, [1^2,3^2,5^2,...,61^2,63^2] and [63^2,61^2,...,3^2,1^2] in base b=241784 are both prime.

V3-007310 | OEIS-A218483

Fermat pseudoprimes to base 2 which are congruent to 1 (mod 8).

For p = 5 the formula becomes 40*n + 25. From the first 15 pseudoprimes divisible by 5, 12 are of the form 40*n + 25 (beside 3 of them which are of the form 40*n + 5). Conjecture: there are no pseudoprimes to base 2 of the form 40*n + 15. Conjecture: If a Fermat pseudoprime to base 2 can be written as 8*p*n + p^2, where n is an integer and p one of its prime factors, then it can be written this way for any of its prime factors. Checked for all pseudoprimes from the sequence above. Conjecture: If a Fermat pseudoprime to base 2 with two prime factors can be written as 8*p1*n + p1^2, where n is a natural number and p1 one of its two prime factors, then it can also be written as 8*p2*(-n) + p2^2, where p2 is the other prime factor. Checked for 4033 = 37*109(n = 9), 4369 = 17*257(n = 30), 4681 = 31*151(n = 15), 8321 = 53*157(n = 13), 18721 = 97*193(n = 12), 23377 = 97*241(n = 18), 31417 = 89*353(n = 33), 31609 = 73*433 (n = 45), 65281 = 97*673(n = 72), 85489 = 53*1613 (n = 195). Conjecture: If a Fermat pseudoprime to base 2 cannot be written as 8*p*n + p^2, where n is an integer and p one of its prime factors, then it cannot be written this way for any of its prime factors. Checked for the following pseudoprimes: 341, 645, 1387, 2047, 2701, 2821, 3277, 4371, 5461, 7957, 10261, 13741, 13747, 13981, 14491, 15709, 19951, 29341, 31621, 42799, 49141, 49981, 55245, 60701, 60787, 63973, 65077, 68101, 72885, 80581, 83333. All three conjectures are true (obvious from new characterization). - _Charles R Greathouse IV_, Dec 07 2014

V3-007358 | OEIS-A219529

Coordination sequence for 3.3.4.3.4 Archimedean tiling.

First few terms provided by _Allan C. Wechsler_; Fred Lunnon and Fred Helenius gave the next few; Fred Lunnon suggested that the recurrence was a(n+3) = a(n) + 16 for n > 1. [This conjecture is true - see the CGS-NJAS link for a proof. - _N. J. A. Sloane_, Dec 31 2017] Conjectured to be a(n) = floor((16n+1)/3) for n>0; a(0) = 1; this is a consequence of the suggested recurrence due to Lunnon (see comments). [This conjecture is true - see the CGS-NJAS link in A296368 for a proof. - _N. J. A. Sloane_, Dec 31 2017]

V3-007359 | OEIS-A219540

a(n) = (n^2 + 2*(Sum_{j = 1..n} j^n)) (mod n^3).

R. Mestrovic conjectures that, for n >= 3, 2*sum(j = 1, n) j^n == -n^2 (mod n^3) implies that n is prime. See proposition 2.2(ii) - the conjecture is proved to be equivalent to Giuga's conjecture. This proves the first half of Mestrovic's conjecture and hence the first half of Giuga's conjecture : If n>2 is prime, a(n)=0. Proof: [1] [(n-k)^n + k^n] mod n^3 with n odd becomes [2] n^2*k^(n-1) mod n^3. k^(n-1) == 1 mod n if n is prime, so we can write k^(n-1) = 1 + jn. Place this back into [2], we find that [2] is just n^2 mod n^3. From [1] we have (n-1)*n^2 = -n^2 mod n^3. Q.E.D. The second half of Mestrovic's conjecture involves proving that if n is composite then a(n)<>0. It is easy enough to prove a(4k+2)<>0 by noticing that the residue must be even on the RHS, but the residue on the LHS is odd. a(8k+4)<>0 by a similar method. - _Jon Perry_, Dec 01 2012

V3-007388 | OEIS-A219838

Number of ways to write n as x + y with 0 < x <= y and (xy)^2 + xy + 1 prime.

Conjecture: a(n) > 0 for all n > 1. Zhi-Wei Sun has made the following general conjecture: For each prime p, any sufficiently large integer n can be written as x + y, where x and y are positive integers with ((x*y)^p - 1)/(x*y - 1) prime. (For p = 5, 7 it suffices to require n > 28 and n > 46 respectively.) Compare this with Sun's another conjecture related to A219791.

V3-007427 | OEIS-A220572

Number of ways to write 2n-1=x+y (x,y>=0) with x^18+3*y^18 prime.

Conjecture: a(n)>0 for every n=1,2,3,.... Moreover, any odd integer greater than 2092 can be written as x+y (x,y>0) with x-3, x+3 and x^18+3*y^18 all prime. Zhi-Wei Sun also made the following general conjecture: For each positive integer m, any sufficiently large odd integer n can be written as x+y (x,y>0) with x-3, x+3 and x^m+3*y^m all prime (and hence there are infinitely many primes in the form x^m+3*y^m). In particular, for m = 1, 2, 3, 4, 5, 6, 18 any odd integer greater than one can be written as x+y (x,y>0) with x^m+3*y^m prime, and for m =1, 2, 3 any odd integer n>15 can be written as x+y (x,y>0) with x-3, x+3 and x^m+3*y^m all prime.

V3-007428 | OEIS-A220670

Coefficient triangle for powers of x^2 of polynomials appearing in a generalized Melham conjecture on alternating sums of third powers of Chebyshev's S polynomials with odd indices. Coefficients in powers of x^2 of 2 + (-1)^n*S(2*n,x).

Coefficient triangle for powers of x^2 of polynomials appearing in a generalized Melham conjecture on alternating sums of third powers of Chebyshev's S polynomials with odd indices. Coefficients in powers of x^2 of 2 + (-1)^n*S(2*n,x). For the original Melham conjecture on sums of odd powers of even-indexed Fibonacci numbers see the references given in A217475. See especially the Wang and Zhang reference given there. An analog conjecture stated for Chebyshev's S polynomials (see A049310) is (Product_{j=0..m} tau(j,x))*(Sum_{k=0..n} ((-1)^k)*(S(2*k-1,x)/x)^(2*m+1))/(P(n,x^2)^2) = H(m,n,x^2), with P(n,x^2) := (1 - (-1)^n*S(2*n,x))/x^2 and certain integer polynomials H with degree (2*m-1)*n + binomial(m-1,2) in x^2. The coefficients of powers of x^2 of the monic integer polynomials tau(n,x) := 2*T(2*n+1,x/2)/x, with Chebyshev's T polynomials, are given by the signed A111125 triangle (see a comment there from Oct 23 2012). The coefficients of the powers of x^(2*j) of the polynomials P(n,x^2) are found in (-1)^(n-1)*A109954(n-1,j). Here the conjecture is considered for m=1 (third powers): H(1,n,x^2) = Sum_{p=0..n} a(n,p)*x^(2*p), n >= 1. It is conjectured that in fact H(1,n,x^2) = 2 + (-1)^n*S(2*n,x). This has been checked by Maple for n=1..100. Therefore we have added a(0,0) = 3 (in the conjecture above this would be the undetermined 0/0). The original Melham conjecture for m=1 (third powers), appears by putting x = i (the imaginary unit): 1*4*sum(F(2*k)^3)/(1-F(2*n+1))^2 = sum(a(n,p)*(-1)^p) = 2 + F(2*n+1) (the unsigned row sums of the present triangle). This m=1 identity is, of course, proved.

V3-007429 | OEIS-A220671

Coefficient array for powers of x^2 of polynomials appearing in a generalized Melham conjecture on alternating sums of fifth powers of Chebyshev S polynomials with odd indices.

Coefficient array for powers of x^2 of polynomials appearing in a generalized Melham conjecture on alternating sums of fifth powers of Chebyshev S polynomials with odd indices. For the generalized Melham conjecture and links to the references concerned with the Melham conjecture on sums of fifth powers of even-indexed Fibonacci numbers see a comment under A220670. Here the conjecture is considered for m=2 (fifth powers): H(2,n,x^2):= product(tau(j,x), j=0..2) * sum(((-1)^k)*(S(2*k-1,x)/x)^5, k=0..n) / (P(n,x^2)^2), with P(n,x^2):= (1 - (-1)^n*S(2*n,x))/x^2. For tau(j,x):= 2*T(2*j+1,x/2)/x, with Chebyshev's T polynomials see a Oct 23 2012 comment on A111125. For the polynomials P see signed A109954. The conjecture is that H(2,n,x^2) is an integer polynomial of degree 3*n: H(2,n,x^2) = sum(a(n,p)*x^(2*p), p=0..3*n), n >= 1. If one puts x = i (the imaginary unit) one obtains the original Melham conjecture for Fibonacci numbers F = A000045. H(2,n,-1) = +44*sum(F(2*k)^5,k=0..n)/(1+F(2*n+1))^2, n>=1, which is conjectured to be -14 - 3*y(n) + 8*y(n)^2 + 4*y(n)^3, with y(n):=F(2*n+1) (see row m=2 of A217475). It is conjectured that H(2,n,x^2) = h(2,n,x^2) - 3*z(n) + 8*z(n)^2 + 4*z(n)^3, with z(n):= ((-1)^n)*S(2*n,x), with h an integer polynomial of degree 3*n. See A220672 for the coefficients of h(2,n,x^2) for n = 1..5. Because h(2,n,-1) = -14 by the usual Melham conjecture, we put h(2,0,x^2) = -14.

V3-007430 | OEIS-A220672

Coefficients of powers of x^2 of polynomials, called h(2,n,x^2), appearing in a conjecture on alternating sums of fifth powers of odd-indexed Chebyshev S polynomials stated in A220671.

Coefficients of powers of x^2 of polynomials, called h(2,n,x^2), appearing in a conjecture on alternating sums of fifth powers of odd-indexed Chebyshev S polynomials stated in A220671. A generalized Melham conjecture involving fifth powers (m=2) of odd-indexed Chebyshev S polynomials (see A049310) is H(2,n,x^2):= (x^2-3)*(x^4-5*x^2+5)*sum(((-1)^k)*(S(2*k-1,x)/x)^(2*m+1), k=0..n)/((1 - (-1)^n*S(2*n,x))/x^2)^2 = h(2,n,x^2) - 3*z(n) + 8*z(n)^2 + 4*z(n)^3, with z(n):= ((-1)^n)*S(2*n,x), and h an integer polynomial of degree 3*n. The present array a(n,p) appears as h(2,n,x^2) = sum(a(n,p)*x^(2*p),p=0..3*n), n >= 1. The entry a(0,0) := -14 has been used because, in accordance with the original Melham conjecture (see a comment on A220671), h(2,n,i^2), with the imaginary unit i, is conjectured to be -14, for all n >= 1. a(n,p) = [x^(2p)] h(0,2,n,x^2), with the polynomial h defined above in a comment. The conjecture is that h is an integer polynomial of degree 3n in x^2.

V3-007485 | OEIS-A221671

Maximum number of squares in a non-constant arithmetic progression (AP) of length n.

González-Jiménez and Xarles (2013) compute a(n) up to a(52) = 12 using elliptic curves (see Table 2, where their Q(N) = a(N)). They do not seem to have noticed that a(n) = A193832(n) for n != 5 in the range where they computed a(n). I conjecture that this formula holds for all n != 5. Bombieri & Zannier prove that a(n) << n^(3/5) (log n)^c for some constant c > 0. It is conjectured that a(n) ~ sqrt(8n/3). - _Charles R Greathouse IV_, Jan 21 2022

V3-007613 | OEIS-A223886

Numbers (binomial(j*k*prime(n), j*prime(n)) - binomial(k*j, j))/(k*prime(n)^3) for k=4, j=3 and n>=2.

This sequence (together with already present in the OEIS A034602 and A217772) is based on Gary Detlefs' conjecture, which he disclosed to me in a private communication on 3/29/13 and recently he gave me permission to make it public. Specifically he wrote to me the following: "I have a conjecture which is broader than the one I submitted, having to do with binomial(k*n,n) mod n^3. It appears that binomial(j*k*n,j*n) mod n^3 will be binomial(k*j,j) for n sufficiently large." In effect above conjecture further extends Wolstenholme's and Ljunggren's ideas and could also be expressed as follows: starting with some specific (for any given unchanged values of integers k>0 and j>0) sufficiently large value of n=N and further on for n>N it is true that (binomial(j*k*prime(n), j*prime(n)) - binomial(k*j, j))/k/(prime(n))^3 = m(j, k, n), where m(j, k, n) are integer values.

V3-007619 | OEIS-A223934

Least prime p such that x^n-x-1 is irreducible modulo p.

Conjecture: a(n) < n*(n+3)/2 for all n>1. The conjecture was motivated by E. S. Selmer's result that for any n>1 the polynomial x^n-x-1 is irreducible over the field of rational numbers. We also conjecture that for every n=2,3,... there is a positive integer z not exceeding the (2n-2)-th prime such that z^n-z-1 is prime, and the Galois group of x^n-x-1 over the field of rationals is isomorphic to the symmetric group S_n.

V3-007663 | OEIS-A224197

Least b > p_n^2 such that [p_1^2,p_2^2,...,p_n^2] in base b is prime, where p_j denotes the j-th prime.

Conjecture: (i) For any positive integer k and distinct positive integers a_1< a_2 < ... < a_n with a_n prime, there are infinitely many integers b > a_n^k such that [a_1^k,a_2^k,...,a_n^k] in base b is prime. This is the k-th power version of the author's conjecture related to A217788. Note that s(m,n) defined there is identical with s_1(m,n). It seems that s_2(m,n) < p_{n+1}*p_{m+n+1}.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-007664 | OEIS-A224210

Least prime p such that sum_{k=0}^n (k+1)^2*x^{n-k} is irreducible modulo p.

Conjecture: a(n) does not exceed the (4n-3)-th prime for each n>0. Moreover, for any integers m>1 and n>0 the polynomial sum_{k=0}^n (k+1)^m*x^{n-k} is irreducible modulo some prime, and its Galois group over the rationals is isomorphic to the symmetric group S_n. Also, for m,n=2,3,... there are infinitely many integers b > n^m such that [n^m,...,2^m,1^m] in base b is prime. We have a similar conjecture with the above (k+1)^m replaced by (2k+1)^m.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-007709 | OEIS-A224887

Honaker trios: Consecutive prime numbers p < q < r such that p | (qr+1).

Caldwell & Cheng show that there are only 3 Honaker trios below 2*10^17 and that these are the only Honaker trios if the Cramér-Granville conjecture is satisfied with a constant M < 199262; they also give other sufficient conditions for the number of Honaker trios to be finite. Strictly speaking, the keywords "fini,full" are thus only conjectured, but given that the Cramér-Granville conjecture is believed to hold with M = 2*exp(-gamma) ~ 1.123, it seems justified to use them.

V3-007717 | OEIS-A224986

a(n) = Product_{k=1..n-4} (n-k-2)!^(k*k!).

Consider words on n symbols that contain every permutation of those n symbols as contiguous substrings. The minimal length of such a string was conjectured to equal A007489(n) (see A180632). This sequence is a lower bound on the number of distinct (up to relabeling the symbols) such strings of the conjectured minimal length. It was conjectured in the Ashlock paper that, for all n, there is only one string of length A007489(n) containing all permutations. This sequence shows that this conjecture fails as n grows. In 2014 Houston has shown that the first conjecture about the minimal length is also false for all n > 5. In particular, A180632(6) <= 872 = A007489(n). - _M. F. Hasler_, Jul 28 2020

V3-007755 | OEIS-A225611

Determinant of the (p_n-1) X (p_n-1) matrix with (i,j)-entry equal to the Legendre symbol ((i^2+6*i*j+j^2)/p_n), where p_n is the n-th prime.

Conjecture: We have a(n) = 0 if p_n == 3 (mod 4). For an odd prime p and integers c and d, _Zhi-Wei Sun_ defined (c,d)_p to be the determinant of the (p-1) X (p-1) matrix whose (i,j)-entry is the Legendre symbol ((i^2+c*i*j+d*j^2)/p). It is easy to see that (-c,d)_p = (-1/p)*(c,d)_p. Sun conjectured that for any integer c and nonzero integer d there are infinitely many odd primes p with (c,d)_p = 0, moreover (c,d)_p = 0 if (d/p) = -1. He also formulated some concrete conjectures in the case (d/p) = 1. For example, (3,3)_p = 0 if p == 11 (mod 12), and (10,9)_p = 0 if p == 5 (mod 12); (3,2)_p = (4,2)_p = 0 if p == 7 (mod 8). On August 12 2013, _Zhi-Wei Sun_ conjectured that for any odd prime p and integers c and d with d not divisible by p, if (c,d)_p is nonzero then its p-adic valuation (i.e., p-adic order) must be even.

V3-007770 | OEIS-A225868

Numbers m for which max_{2 <= k <= (m-2)/2} Sum_{d>1, d|m+k, k|m+d} 1 = 3.

Terms >= 53 are primes p such that p+2 is either prime or semiprime or, relatively rarely, the cube of a prime. However, according to calculations by _Peter J. C. Moses_, up to 4.2*10^13 there are no numbers p in the sequence for which p+2 is cube of a prime. One can prove that if such a prime p exists, then it is necessary (but not sufficient) for all numbers of the quadruple {r, 2*r - 1, 4*r^2 - 6*r + 3, (2*r - 1)^3 - 2} to be primes, where r == 19 (mod 30) is defined by the equality (2r-1)^3 - 2 = p. The first 3 suitable values of r are 229, 3109, and 17449. But the corresponding p's are not in the sequence. We conjecture that all primes of the sequence are Chen primes, that is, all of them are in A109611.

V3-007787 | OEIS-A226115

Least positive integer not of the form p_m - p_{m-1} + ... +(-1)^(m-k)*p_k with 0 < k < m <= n, where p_j denotes the j-th prime.

Conjecture: sqrt(2*a(n)) > sqrt(p_n)-0.7 for all n > 0, and a(n) is even for any n > 7.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, May 27 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-007788 | OEIS-A226135

Let abcd... be the decimal expansion of n. Number of iterations of the map n -> f(n) needed to reach a number < 10, where f(n) = a^b + c^d + ... which ends in an exponent or a base according as the number of digits is even or odd.

Inspired by the sequence A133501 (Number of steps for "powertrain" operation to converge when started at n). It is conjectured that the trajectory for each number converges to a single number < 10. The conjecture is true, since f(x) < x trivially holds for x > 10^10 and I have verified that for every 10 <= x <= 10^10 there is a k such that f^(k)(x) < x, where f^(k) denotes f applied k times. Both the conventions 0^0 = 1 and 0^0 = 0 have been taken into account. - _Giovanni Resta_, May 28 2013

V3-007858 | OEIS-A226896

Position of log n in the joint ranking of harmonic numbers H(k) and {log k}, for k >= 1; complement of A226894.

If, in the definition, log k is replaced by g + log k, where g is the Euler-Mascheroni constant, then the position of log n is 2n-1, which leads to a conjecture: limit[1/(H(n) - g - log n) - 2n] = 1/3.

V3-007937 | OEIS-A227609

Determinant of the (p_n-1)/2 X (p_n-1)/2 matrix with (i,j)-entry being the Legendre symbol((i^2+j^2)/p_n), where p_n is the n-th prime.

Conjecture: p_n never divides a(n), and moreover -a(n) is a quadratic residue mod p_n. Zhi-Wei Sun also made the following conjecture: These were proved in version 9 of arXiv:1308.2900 (2018). In addition, the author has the following new conjecture. Conjecture: For any prime p == 3 (mod 4), the number -S(1,p) is a positive square divisible by 2^((p-3)/2), i.e., -S(1,p) = (2^((p-3)/4)*m)^2 for some positive integer m. - _Zhi-Wei Sun_, Sep 09 2018

V3-007939 | OEIS-A227631

Array t(n,k): row n consists of the positive integers m for which the least splitter of H(m) and H(m+1) is n, where H denotes harmonic number.

Suppose that x < y. The least splitter of x and y is introduced here as the least positive integer d such that x <= c/d < y for some integer c; the number c/d is called the least splitting rational of x and y. Conjecture: every row of the array in A227631 is infinite, and every positive integer occurs exactly once. Let r be the limiting ratio of consecutive terms of row 1; is r = e?

V3-007964 | OEIS-A227968

Determinant of the (p_n+1)/2 X (p_n+1)/2 matrix with (i,j)-entry (i,j=0,...,(p_n-1)/2) equal to the Legendre symbol((i^2+j^2)/p_n), where p_n is the n-th prime.

Conjecture: 2*a(n) is always a quadratic residue mod p_n. Zhi-Wei Sun also made the following general conjecture: The general conjecture mentioned above was proved in a recent preprint of Zhi-Wei Sun.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Aug 01 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-007965 | OEIS-A227971

Determinant of the (p_n+1)/2 X (p_n+1)/2 matrix with (i,j)-entry (i,j=0,...,(p_n-1)/2) being the Legendre symbol((i+j)/p_n), where p_n is the n-th prime.

Conjecture: If p_n == 1 (mod 4), then a(n) == ((p_n-1)/2)! (mod p_n). If p_n == 3 (mod 4), then a(n) == (2/p_n) (mod p_n). Zhi-Wei Sun also made the following general conjecture: On August 19 2013, Zhi-Wei Sun found a formula for a(n). Namely, he made the following conjecture: If p_n == 1 (mod 4) and e(p_n)^{h(p_n)} = (a_n + b_n*sqrt(p_n))/2 with a_n and b_n integers of the same parity (where e(p_n) and h(p_n) are the fundamental unit and the class number of the quadratic field Q(sqrt(p_n)) respectively), then a(n) = - (2/p_n)*2^{(p_n-3)/2}*a_n. If p_n > 3 and p_n == 3 (mod 4), then a(n) = 2^{(p_n-1)/2}. On August 19 2013, Zhi-Wei Sun proved all the conjectured congruences mentioned above by using the identity D(c,d,n) = (-d)^{n*(n+1)/2}*(n!)^{n+1}, where D(c,d,n) is the (n+1) X (n+1) determinant with (i,j)-entry equal to (i+d*j+c)^n for all i,j = 0,...,n. For any prime p == 1 (mod 4) he showed that R(d,p) == (d*(d/p))^{(p-1)/4}*((p-1)/2)! (mod p). Note also that the formula for a(n) found by Sun on August 9, 2013 is actually equivalent to Chapman's result on the evaluation of the determinant |((i+j-1)/p)|_{i,j=1,...,(p+1)/2}.

V3-007972 | OEIS-A228039

Thue-Morse sequence along the squares: A010060(n^2).

(Adapted from Drmota, Mauduit, and Rivat) The Thue-Morse sequence T(n) is a 0-1-sequence that can be defined by T(n) = s2(n) mod 2, where s2(n) denotes the binary sum-of-digits function of n (that is, the number of powers of 2). By definition it is clear that 0 and 1 appear with the same asymptotic frequency 1/2. However, there is no consecutive block of the form 000 or 111, so that the Thue-Morse sequence is not normal. (A 0-1-sequence is normal if every finite 0-1-block appears with the asymptotic frequency 1/2^k, where k denotes the length of the block.) Mauduit and Rivat (2009) showed that the subsequence T(n^2) also has the property that both 0 and 1 appear with the same asymptotic frequency 1/2. This solved a long-standing conjecture by Gelfond (1967/1968). Drmota, Mauduit, and Rivat (2013) proved that the subsequence T(n^2) is actually normal.

V3-007974 | OEIS-A228060

Irregular table of conjectural numbers. Let len(n) be the length (including n) of the Collatz (3x+1) iteration of n. The number n is in row n - len(n).

Irregular table of conjectural numbers. Let len(n) be the length (including n) of the Collatz (3x+1) iteration of n. The number n is in row n - len(n). This sequence is labeled conjectural because (I think) we currently have no way of knowing whether there is some large n that has a long Collatz iteration. Sequence A220139 computes the trajectory for some large numbers, all of which have moderately small length (see A220140). The table below shows numbers in the same row. Notice that each row has only a few numbers. Row 15 is the first with 4 numbers: 26, 37, 103, 124. Row 324 is the first with 5 numbers: 336, 357, 370, 414, 440. Row 16028 has 6 numbers. Row 34937 has 7 numbers. No row in the first 10^7 rows has more than 7 numbers. This sequence is fairly linear; in the first 10^7 terms, no adjacent terms differ by more than 547.

V3-007975 | OEIS-A228077

Determinant of the (p_n-1)/2 X (p_n-1)/2 matrix with (i,j)-entry being the Legendre symbol ((j-i)/p_n), where p_n is the n-th prime.

Conjecture: In the case p_n == 1 (mod 4), (2/p_n)*a(n) is a positive odd integer whose prime factors are all congruent to 1 modulo 4, and moreover for some integer b(n) we have b(n) + (2/p_n)*a(n)*sqrt(p_n) = e(p_n)^{(2-(2/p_n))h(p_n)}, where e(p_n) and h(p_n) are the fundamental unit and the class number of the real quadratic field Q(sqrt(p_n)) respectively. M. Vsemirnov has proved _Robin Chapman_'s conjecture on the evaluation of the determinant of the (p+1)/2-by-(p+1)/2 matrix with (i,j)-entry (i,j = 0,...,(p-1)/2) being the Legendre symbol ((j-i)/p), where p is an odd prime. On Aug 14 2013, _Robin Chapman_ informed the author that he first made the conjecture about the exact value of a(n) in a private manuscript dated Aug 05 2003.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-007976 | OEIS-A228095

Determinant of the p_n X p_n matrix with (i,j)-entry equal to the Legendre symbol ((i^2 + 3*i*j + 3*j^2)/p_n) for all i,j = 0, 1, ..., p_n-1, where p_n is the n-th prime.

Conjecture: a(n) = 0 if p_n == 5 (mod 6). For an odd prime p and integers c and d, _Zhi-Wei Sun_ defined [c,d]_p to be the determinant of the p X p matrix with (i,j)-entry equal to the Legendre symbol ((i^2+c*i*j+d*j^2)/p). It is easy to see that [-c,d]_p = (-1/p)*[c,d]_p. Sun conjectured that for any integer c and nonzero integer d there are infinitely many odd primes p with [c,d]_p = 0. He also conjectured that if (c,d)_p (defined in the comments in A225611) is nonzero with d not divisible by p, then [c,d]_p/(c,d)_p equals (1-p)/(p-2) or (p-1)/2 according as p divides c^2-4*d or not. He also made some concrete conjectures, for example, [3,2]_p = 0 if p == 3 (mod 4); and [4,2]_p = 0 if p == 5 or 7 (mod 8). On Aug 12 2013, _Zhi-Wei Sun_ conjectured that for any odd prime p and integers c and d with d not divisible by p, if [c,d]_p is nonzero then its p-adic valuation (i.e., p-adic order) must be even.

V3-008003 | OEIS-A228379

Determinant of the n X n matrix with (i,j)-entry equal to (i^2+j^2)^n for all i,j = 0,...,n-1.

Conjecture: If n > 2, then (-1)^{n(n-1)/2}*a(n) > 0 and 2*Product_{k=1..n} (k!*(2k-1)!) divides a(n). This conjecture implies that if p = 2*n-1 > 3 is a prime then we have a((p+1)/2) == 0 (mod p). So Sun's Conjecture 3.7 in the reference would follow from the above conjecture. If b(n) denotes the n X n determinant with (i,j)-entry equal to (i+j)^n for all i,j = 0,...,n-1, then we conjecture that b(n)*(-1)^(n*(n-1)/2) / ((n-2)!*n*Product_{k=1..n} (k!)) is a positive integer for any integer n > 2.

V3-008005 | OEIS-A228407

The digits of a(n) and a(n+1) together can be reordered to form a palindromic integer; the lexicographically earliest injective sequence of nonnegative integers with this property.

It is conjectured that the sequence is a permutation of the nonnegative integers (motivating the choice of offset 0), i.e., that all numbers will eventually occur. (The conjecture is true - see below. - _N. J. A. Sloane_, Nov 12 2013) To test this conjecture, consider the indices n where the smallest integers not yet used occur. If the conjecture is true, this is equivalent to a(m)>a(n) for all m>n; if not, then this list ends at the first missing number. These [n,a(n)] are: [0, 0], [2, 1], [6, 2], [10, 3], [17, 4], [34, 5], [45, 6], [65, 7], [81, 8], [118, 9], [119, 29], [122, 39], [145, 44], [152, 45], [197, 46], [230, 47], [271, 48], [362, 49], [533, 57], [740, 58], [754, 68], [816, 69], [855, 89], [856, 98], [857, 198], [1011, 211], [1012, 222], [1110, 224], [1232, 225], [1385, 234], [1406, 236], [1413, 237], [1767, 238], [1921, 239], [2555, 257], [2590, 259], [2597, 269], [4354, 279], [4355, 297], [4361, 379], [4362, 397], [4368, 479], [4369, 497],...

V3-008008 | OEIS-A228425

Number of ways to write n = x + y (x, y > 0) with x*(x+1)/2 + y^2 prime.

Conjecture: a(n) > 0 for all n > 1. For m = 3, 4, 5, ... the m-gonal numbers are given by p_m(x) = (m-2)*x*(x-1)/2 + x (x = 0, 1, 2, ...). We note that there are many pairs m > k > 2 such that all sufficiently large integers n can be written as x + y (x, y > 0) with p_k(x) + p_m(y) prime. For example, we conjecture that the pair (k, m) works if k is among 3, 4, 6 , and m > k is not congruent to k modulo 2. For k = 5, we guess that the pair (5, m) works if m is congruent to 0 or 4 modulo 6. We conjecture that the only pairs (k,m) with 2 < k <= 10 and k< m <= 100 such that any integer n > 1 can be written as x + y (x, y > 0) with p_k(x) + p_m(y) prime, are as follows: (3,4),(3,6),(3,28),(3,46),(3,52),(3,82),(3,88),(4,7),(4,15),(4,25),(4,27),(4,37),(4,43),(4,63),(4,67),(4,97),(6,25),(6,43),(6,73),(7,10),(7,18),(7,100),(10,15),(10,19),(10,27),(10,37),(10,55),(10,75),(10,79),(10,87),(10,99). We also conjecture that any integer n > 1 can be written as x + y (x, y > 0) with p_k(x) + p_{k+1}(y) prime, if and only if k is among 3, 39, 99.

V3-008037 | OEIS-A228626

Number of Hamiltonian cycles in the undirected simple graph G_n with vertices 1,...,n which has an edge connecting vertices i and j if and only if |i-j| is prime.

Conjecture: a(n) > 0 for all n > 4. In other words, for each n = 5,6,... there is a permutation i_1,...,i_n of 1,...,n such that |i_1-i_2|, |i_2-i_3|, ..., |i_{n-1}-i_n| and |i_n-i_1| are all prime. Note that this conjecture is different from the prime circle problem in A051252 though they look similar. On August 30 2013, Yong-Gao Chen (from Nanjing Normal University) confirmed the conjecture for n > 12 as follows: If n = 2*k then G_n contains a Hamiltonian cycle (1,3,5,2,7,9,...,2k-5,2k-3,2k,2k-2,2k-4,2k-1,2k-6,2k-8,...,6,4);

V3-008050 | OEIS-A228885

Determinant of the n X n matrix with (i,j)-entry equal to 1 or 0 according as i + j is coprime to n or not.

Conjecture: If n is squarefree, then (-1)^(n*(n-1)/2)*a(n) > 0. Conjectures from _Ridouane Oudra_, Mar 13 2025: (Start)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Sep 06 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008051 | OEIS-A228886

Number of permutations i_0,i_1,...,i_n of 0,1,...,n with i_0 = 0 and i_n = n, and with i_0+i_1, i_1+i_2, ..., i_{n-1}+i_n, i_n+i_0 all coprime to both n-1 and n+1.

Conjecture: a(n) > 0 except for n = 2, 4. Note that this conjecture is stronger than the one stated in the comments in A228860. Also, there is no permutation i_0, ..., i_7 of 0, ..., 7 with i_0+i_1, i_1+i_2, ..., i_6+i_7, i_7+i_0 all coprime to 7*13 - 1 = 90. We have some other similar conjectures. For example, for any positive integer n there is a permutation

i_0,i_1,...,i_n of 0,1,...,n with i_0 = 0 and i_n = n such that i_0 + i_1, i_1 + i_2, ..., i_{n-1} + i_n, i_n + i_0 are all relatively prime to both 2*n-1 and 2*n+1. On Sep 10 2013, Zhi-Wei Sun proved the conjecture for any positive odd integer n. In fact, if n == 1 or 3 (mod 6) then we may take the permutation 0,n-2,2,n-4,4,...,1,n-1,n which meets the requirement; if n == 3 or 5 (mod 6) then the permutation 0,1,n-1,3,n-3,...,n-2,2,n suffices for our purpose.

Conjecture: all terms are positive.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Vladimir Shevelev_, Sep 11 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008069 | OEIS-A229038

Number of undirected circular permutations (i_1, ..., i_n) of 1, ..., n such that all the n sums i_1^2+i_2^2, ..., i_{n-1}^2+i_n^2, i_n^2+i_1^2 are among those integers m with the Jacobi symbol (m/(2*n+1)) equal to 1.

Conjecture: a(n) > 0 if 2*n+1 is a prime greater than 13. When p = 2*n+1 > 13 is a prime, the conjecture indicates that there is a numbering a_1, a_2, ..., a_n of all the (p-1)/2 = n quadratic residues modulo p such that all the n adjacent sums a_1+a_2, a_2+a_3, ..., a_{n-1}+a_n, a_n+a_1 are also quadratic residues modulo p. Zhi-Wei Sun also made the following conjecture: Noga Alon has confirmed this conjecture. See also A229878 for a stronger conjecture which remains open.

V3-008084 | OEIS-A229136

Number of solutions to Sum_{i=1..n} x_i^2 == 1 (mod 4) with x_i in 0..3.

Conjecture: a(n) = A131885(n)*2^(n-1) for n >= 1. [Corrected by _Petros Hadjicostas_, Dec 20 2019] It follows that 2*b(n-1) = 4*b(n-2) - 4*b(n-3) + 2^(n-2) for n >= 4. Subtracting the last equation from the previous one, we get (after some algebra) b(n) = 4*b(n-1) - 6*b(n-2) + 4*b(n-3) for n >= 4. We can easily verify that b(1) = 2, b(2) = 4, and b(3) = 6, and this proves that b(n) = A131885(n) for n >= 1. This proves the above conjecture. (End)

Number of ways to write n = (p - 1)/6 + q, where p is a prime, and q is a term of the sequence A000009.

Conjecture: a(n) > 0 for all n > 1. Also, any integer n > 1 can be written as (p + 1)/6 + q, where p is a prime and q is a term of A000009.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Dec 19 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008140 | OEIS-A229878

a(n) = number of undirected circular permutations tau of 1, ..., (p_n-1)/2 such that tau(1)^2 + tau(2)^2, tau(2)^2 + tau(3)^2, ..., tau((p_n-3)/2)^2 + tau((p_n-1)/2)^2, tau((p_n-1)/2)^2 + tau(1)^2 give all the (p_n-1)/2 quadratic residues modulo p_n, where p_n is the n-th prime.

Conjecture: a(n) > 0 for all n > 6. In other words, for any prime p = 2*n+1 > 13, there is a circular permutation a_1, ..., a_n of the n quadratic residues modulo p such that a_1+a_2, a_2+a_3, ..., a_{n-1}+a_n, a_n+a_1 give all the n quadratic residues modulo p. Zhi-Wei Sun also made the following general conjecture:

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Zhi-Wei Sun_, Oct 02 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008141 | OEIS-A229899

a(n) = |{0<g<p_n: g-1, g, g+1 are primitive roots mod p_n}|, where p_n denotes the n-th prime.

Conjecture: a(n) > 0 except for n = 1, 2, 3, 4, 6, 10, 18. In other words, for any prime p > 7 not equal to 13 or 29 or 61, there are three consecutive integers which are primitive roots modulo p. Zhi-Wei Sun also made the following conjectures: The conjecture that a(n) > 0 except for n = 1, 2, 3, 4, 6, 10, 18 follows from Theorem 1 of Cohen, Oliveira e Silva and Trudgian (2015). For an odd prime power q, their theorem states that F_q contains three consecutive primitive elements if and only if q is not one of 3, 5, 7, 9, 13, 25, 29,

61, 81, 121, 169. The primes in this list are 3, 5, 7, 13, 29 and 61, namely p_2, p_3, p_4, p_6, p_10 and p_18. The remaining exception n = 1 (p = 2) is immediate, since at least one of any three consecutive integers is divisible by 2. - _Eiver Rodríguez_, Sep 05 2026

V3-008149 | OEIS-A230073

Coefficients of the minimal polynomials of the algebraic numbers sqLhat(2*l) from A230072, l >= 1, related to the square of all length in a regular (2*l)-gon inscribed in a circle of radius 1 length unit.

Mustonen's polynomials from his eq. (6) for the even n case coincide with PsqL(l, x) precisely for l = 2^k, k>=1, and for l = 1 (k=0) one has to take the negative. In all other cases the degrees do not fit (Mustonen's polynomials become reducible over the integers). His conjecture for the coefficients can then be rewritten as a conjecture for the present polynomials psqLhat(2^k, x), k >= 0 (see the formula section). S. Mustonen also conjectured about the other zeros of his polynomials. Mustonen's conjecture (adapted, see a comment above) is: a(2^k,m) = ((-1)^m)*binomial(2*2^k,2*m), k >= 1, and for k=0 a(1,0) = -1 and a(1,1) = 1 is trivial.

V3-008171 | OEIS-A230312

Squares which cannot be written as the sum of a smaller nonzero square and twice a triangular number.

The conjecture a(n) = A001912(n)^2 (mentioned in the formula part) is easy. In fact, any prime divisor of 4*n^2 + 1 is congruent to 1 modulo 4 and hence it can be written as a sum of two squares. Thus 4*n^2 + 1 = (2*n)^2 + 1^2 is composite if and only if it can be written as a sum of two squares in at least two ways. So the conjecture follows immediately. - _Zhi-Wei Sun_, Feb 23 2014 Conjecture: a(n) = A001912(n)^2, that is, squares of numbers n such that 4n^2 + 1 is prime. - _Alonso del Arte_, Dec 20 2013

V3-008190 | OEIS-A230578

Smallest number larger than 1 such that multiplying n-th highly composite number by a(n) will give a highly composite number.

Conjecture: all a(n) are prime numbers. This conjecture is false: a(643) = 6 is not prime. - _Alois P. Heinz_, Oct 23 2013

猜想/问题提及段 | historical_or_current_mention_unreviewed | _J. Lowell_, Oct 23 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008191 | OEIS-A230579

a(n) = 2^n mod 341.

Granted that without a computer, the task of calculating 2^340 - 1 and dividing by 341 is tedious and error-prone, thus discouraging the discovery of that number as a counterexample to the so-called Chinese hypothesis.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Alonso del Arte_, Oct 23 2013 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008192 | OEIS-A230596

Number of ways to write n = x + y + z with 0 < x <= y <= z such that x*y*z is a triangular number, and that x is a triangular number of the form (p^2 - 1)/8 with p an odd prime.

Conjecture: (i) a(n) > 0 except for n = 1, 2, 4, 7.

V3-008197 | OEIS-A230762

List of commonest number of decompositions of 2k into an unordered sum of two odd primes in range 3 <= k <= m, integer m >= 3, where m is explained below.

Hypothesis: With the increase of m, the commonest number of decompositions of 2n into an unordered sum of two odd primes in the range of 3 <= k <= m ascends. This hypothesis derives that the corresponding smallest m to the terms of this sequence makes an ascending sequence. Or say, when testing with m ascending, once a number a(n) enters this sequence, no number smaller than a(n) will be able to enter this sequence if they had not enter previous.

V3-008263 | OEIS-A232565

a(n) is the smallest k such that 2^(2^n) - 2^k - 1 is prime, or -1 if no such k exists.

If n > 2, then the (largest) prime P(n) = 2^(2^n)-2^a(n)-1 is a de Polignac number (A065381); i.e., P(n)-2^m is not prime. It seems that if n > 6, then |P(n)-2^m| is composite for every natural m and P(n)*2^m-1 is composite (by the dual Riesel conjecture). So if n > 6, then the prime P(n) may be a Riesel number (A182296). For example, the prime P(7) = 2^(2^7)-(2^18+1) is the first candidate (note that 2^18+1 is the smallest de Polignac number of form 2^k+1). Also, by Crocker's theorem, the smallest number of form 2^(2^n)-2^m-1, namely 2^(2^n-1)-1 is a de Polignac number (A006285) and for n > 6 may be a dual Riesel number (A101036). For example, the double Mersenne prime 2^(2^7-1)-1 probably is a dual Riesel number. It is not known whether these are Riesel numbers with a covering set. - _Thomas Ordowski_, Jan 24 2024

V3-008266 | OEIS-A232624

Coefficient array for the minimal polynomials of 2*cos(2*Pi/n) for n >= 1.

Conjecture: For odd n > 1, the term of the highest degree of (MPR2(2n, x) - MPR2(n, x))/2 is (-1)^omega(n) * x^(phi(n)/2-n/rad(n)) = A076479(n) * x^(A023022(n)-A003557(n)). For example, for n = 15, (MPR2(30, x) - MPR2(15, x))/2 = x^3 - 4x; for n = 105, (MPR2(210, x) - MPR2(105, x))/2 = -x^23 + ...; for n = 225, (MPR2(450, x) - MPR2(225, x))/2 = x^45 + ... If this is true, then for odd n > 1, a(n,A023022(n)-k) = a(2n,A023022(n)-k) = 0 for k = 1, 3, ..., A003557(n)-2; a(n,A023022(n)-A003557(n)) = -A076479(n) and a(2n,A023022(n)-A003557(n)) = A076479(n). - _Jianing Song_, Jul 11 2019 Conjecture: Let MPR2(n, x) equal the odd indexed (n) monic polynomial. If the number of roots with negative signs is even, then n is a term in A014659. Example: n = 7 for x^3 + x^2 - 2x - 1, having two negative roots, (-445041..., and -1.801937...). Two is even so the integer 7 is in A014659. n = 9 for the polynomial x^3 - 3x + 1, with one negative root, (-1.87938). The term 9 is in A014657. - _Gary W. Adamson_, Oct 20 2021

V3-008267 | OEIS-A232636

The second largest value of permanent of (0,1) square matrices of order n with row and column sums equal to 3.

We conjecture that formula below also holds for other values. All terms for n>30 not divisible by 3 are conjectural since our method is based on the following very plausible but yet not proved conjecture with confirms in many cases and without counterexample since 1992 (when it was posed, see ref. [11] in Shevelev link). Let L_n be the set of considered n X n (0,1)-matrices with all row and column sums equal to 3. Let S_n be the subset of completely indecomposable such matrices, i.e., not containing submatrices from L_m (m<n). Let M(n) be the maximal value of permanent on S_n. Then M(n_1+n_2) <= M(n_1)*M(n_2). V. I. Bolshakov proved the result for n divisible by 3, using quite different arguments which, generally speaking, do not work for other n and for third, fourth, etc. largest values of permanent, where our (yet conditional) method does work successfully, at least for sufficiently large n. Conjectures from _Colin Barker_, May 27 2016: (Start)

V3-008287 | OEIS-A232895

Sequence (or tree) S of all positive integers in the order generated by these rules: 1 and 2 are in S; if x is in S then x + 2 and 2*x are in S, where duplicates are deleted as they occur.

Let S be the sequence (or tree) of numbers generated by these rules: 1 and 2 are in S; if x is in S then x + 2 and 2*x are in S, where duplicates are deleted as they occur. Every positive integer occurs exactly once in S, so that S is a permutation of the natural numbers. Deleting duplicates as they occur, the generations of S are given by g(1) = (1,2), g(2) = (3,4), g(3) = (5,6,8), g(4) = (7,10,12,16), ... Concatenating gives 1,2,3,4,5,6,8,... Conjecture: the position of the n-th odd positive integer in S is the linearly recurrent sequence given by A232896(n) for n>=1.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-008356 | OEIS-A233593

Positive integers k such that the continued fraction expansion sqrt(k) = c(1) + c(1)/(c(2) + c(2)/(c(3) + c(3)/....)) is aperiodic.

The cases with known periodic expansions, listed in A233592, all become periodic after just two leading terms. In contrast, the Blazys's expansion of sqrt(a(k)) for every member a(k) of this list remains aperiodic up to at least 1000 terms. It is therefore conjectured, though not proved, that these expansions are indeed aperiodic.

V3-008396 | OEIS-A234788

Solutions to numerator(Bernoulli(k)) == denominator/6 (Bernoulli(k)) (mod 30).

Conjecture: the residues mod 30 of the numerator and the denominator/6 of Bernoulli(20(n-1) + 2) are equal. Conjecture: the only solutions to the above equation are {1, 7, 11, 13, 17, 19, 23 or 29}. Observation: the differences between these solutions are (6, 4, 2, 4, 2, 4, 6), a sequence with bilateral symmetry. Program checks all nonzero Bernoulli numbers except B(1), but if the above conjecture is true, then it needs check only every 20th Bernoulli Number starting with B(2). This formula is conjectural, but the program verified it for each of the first 300 numbers in this sequence: to obtain k from the n of this sequence, k = 20(n-1) + 2.

V3-008469 | OEIS-A236066

Primes p with g(p), g(g(p)), g(g(g(p))), g(g(g(g(p)))), g(g(g(g(g(p))))) all prime, where g(n) = prime(n) - n - 1.

Conjecture: For any integer m > 1, there are infinitely many chains p(1) < ... < p(m) of m primes with p(k+1) = prime(p(k)) - p(k) - 1 for all 0 < k < m. This is similar to the conjecture in A235925.

V3-008552 | OEIS-A237123

Number of ways to write n = i + j + k with 0 < i < j < k such that phi(i), phi(j) and phi(k) are all cubes, where phi(.) is Euler's totient function.

Conjecture: For each k = 2, 3, ... there is a positive integer s(k) such that any integer n >= s(k) can be written as i_1 + i_2 + ... + i_k with 0 < i_1 < i_2 < ... < i_k such that all those phi(i_1), phi(i_2), ..., phi(i_k) are k-th powers. In particular, we may take s(2) = 70640, s(3) = 935 and s(4) = 3273.

V3-008573 | OEIS-A237593

Triangle read by rows in which row n lists the elements of the n-th row of A237591 followed by the same elements in reverse order.

Conjecture 1: the area under the n-th Dyck path equals A024916(n), the sum of all divisors of all positive integers <= n. If the conjecture is true then the n-th Dyck path represents the boundary segments after the alternating sum of the elements of the n-th row of A236104. Conjecture 2: two adjacent Dyck paths never cross (checked by hand up to n = 128), hence the total area between the n-th Dyck path and the (n-1)-st Dyck path is equal to sigma(n) = A000203(n), the sum of divisors of n. Checked _Michel Marcus_'s conjecture with two Mathematica functions up to n=100000, for more information see A240542. - _Hartmut F. W. Hoft_, Jul 17 2014

V3-008577 | OEIS-A237606

Positive integers k such that x^2 - 8xy + y^2 + k = 0 has integer solutions.

Even powers of terms as well as products of an even number of terms belong to A243188. This can be proved with respect to the forms [a,0,-c] and [a, 0, +c] by the following identities: (au^2 - cv^2)(ax^2 - cy^2) = (aux + cvy)^2 - ac(uy + vx)^2 and (au^2 + cv^2)(ax^2 + cy^2) = (aux - cvy)^2 + ac(uy + vx)^2 for all a, c, u, v, x, y in R. This can be verified by expanding both sides of the equations. Generalization (conjecture): This multiplication rule applies to all sequences represented by any binary quadratic form [a, b, c]. Odd powers of terms as well as products of an odd number of terms belong to the sequence. This can be proved with respect to the forms [a,0,-c] and [a, 0, +c] by the following identities: (as^2 - ct^2)(au^2 - cv^2)(ax^2 - cy^2) = a[s(aux + cvy) + ct(uy + vx)]^2 - c[as(uy + vx) + t(aux + cvy)]^2 and (as^2 + ct^2)(au^2 + cv^2)(ax^2 + cy^2) = a[s(aux - cvy) - ct(uy + vx)]^2 + c[as(uy + vx) + t(aux - cvy)]^2 for all a, c, s, t, u, v, x, y in R. This can be verified by expanding both sides of the equations. Generalization (conjecture): This multiplication rule applies to all sequences represented by any binary quadratic form [a, b, c]. Generalization (conjecture): If there are three sequences of a given positive discriminant that are represented by the forms [a1, b1, c1], [a2, b2, c2] and [a1*a2, b3, c3] for a1, a2 != 1, then the BCD rules apply to these sequences. (End)

V3-008607 | OEIS-A238003

Number of partitions of n not having depth 1; see Comments.

The depth of a partition is defined at A237685 as follows. Suppose that P is a partition of n. Let x(1), x(2), ..., x(k) be the distinct parts of P, and let m(i) be the multiplicity of x(i) in P. Let f(P) be the partition [m(1)*x(1), m(2)*x(2), ..., x(k)*m(k)] of n. Define c(0,P) = P, c(1,P) = f(P), ..., c(n,P) = f(c(n-1,P)), and define d(P) = least n such that c(n,P) has no repeated parts; d(P) is the depth of P. Conjecture: lim_{n->infinity} a(n)/A000041(n) = 1.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Clark Kimberling_, Feb 19 2014 | 2026-10-24

V3-008631 | OEIS-A238509

a(n) = |{0 < k < n: p(n) + p(k) - 1 is prime}|, where p(.) is the partition function (A000041).

Conjecture: (i) a(n) > 0 for all n > 1. Also, if n > 2 is different from 8 and 25, then p(n) + p(k) + 1 is prime for some 0 < k < n.

V3-008632 | OEIS-A238516

a(n) = |{0 < k < n: (p(k)+1)*p(n) + 1 is prime}|, where p(.) is the partition function (A000041).

Conjecture: (i) a(n) > 0 for all n > 1. Also, for any integer n > 4 there is a positive integer k < n with (p(k)-1)*p(n) - 1 prime.

V3-008633 | OEIS-A238549

a(n) is one fourth of the total number of free ends of 4 line segments expansion at n iterations (see Comments lines for definition).

We take the official definition to be that provided by the PARI program. From this the assertions in the Formula section follow (they were formerly stated as conjectures). - _N. J. A. Sloane_, Feb 24 2019

V3-008634 | OEIS-A238568

a(n) = |{0 < k < n: n^2 - pi(k*n) is prime}|, where pi(x) denotes the number of primes not exceeding x.

Conjecture: (i) a(n) > 0 for all n > 1, and a(n) = 1 only for n = 2, 3, 4, 8, 10, 24, 41.

V3-008635 | OEIS-A238570

a(n) = |{0 < k < n: pi((k+1)^2) - pi(k^2) and pi(n^2) - pi(k^2) are both prime}|, where pi(x) denotes the number of primes not exceeding x.

Conjecture: (i) a(n) > 0 for all n > 1.
