V3-013212 | OEIS-A303769

a(0) = 0, a(n+1) is either the largest number obtained from a(n) by toggling a single 1-bit off (to 0) if no such number is yet in the sequence, otherwise the least number not yet in sequence that can be obtained from a(n) by toggling a single 0-bit on (to 1). In both cases the bit to be toggled is the rightmost possible that results yet an unencountered number.

The original, but now conjectural, alternative definition is: The equivalence of these definitions is still conjectural. The official definition of this sequence follows the latter one. - _Antti Karttunen_, Jun 08 2018 a(n) = A048675(A303762(n)). [The original definition, now conjectured]

V3-013223 | OEIS-A304174

Decimal expansion of 2^61/(3^32*993), the conjectured maximal residue in the Collatz 3x+1 problem.

Decimal expansion of 2^61/(3^32*993), the conjectured maximal residue in the Collatz 3x+1 problem. The residue of n in the 3x+1 problem is defined as the ratio 2^h(n)/(3^t(n)*n), where h = A006666 is the number of halving steps, and t = A006667 is the number of tripling steps. It is conjectured that n = 993 yields the highest possible residue. See e.g. the Roosendaal page, and A127789 for indices of record residues.

V3-013225 | OEIS-A304178

Number of distinct sets of palindrome prefix lengths, over all binary palindromes of length n.

Claesson's conjecture: for n>=3, a(n+1) equals the number of Wilf-classes of Hertzsprung patterns of length n. These patterns correspond to "rigid patterns" from Myers's work. Bóna studied them under the name "very tight patterns". The number of Wilf-classes of Hertzsprung patterns can also be interpreted as the number of different autocorrelation polynomials of self-overlapping permutations. For more details, definitions and examples, see works by Claesson, Bóna, Kirgizov-Nurligareev and Myers in the links section. - _Sergey Kirgizov_, Nov 28 2024

V3-013226 | OEIS-A304239

Indices for which the Mertens function A002321 reaches its extremum between subsequent zeros for the first time.

This is related to the Mertens conjecture, more precisely to record values of Mertens function A002321 in the following sense: Due to the short-scale and long-scale oscillations of A002321, it is less appealing to consider record values in the usual sense (cf. A051402), which yields many slowly growing records and record indices lying closely together, during the approach of a "long-scale" record. Therefore this sequence considers maxima or minima between two subsequent zeros, ignoring the empty intervals between immediately adjacent zeros A002321(k) = A002321(k+1) = 0.

V3-013254 | OEIS-A305024

Minimal number of squares, not all equal to 1, having as sum prime(n), such that their squares also sum to a prime; 0 if no such decomposition exists.

It has been conjectured (cf. A126769) that any prime p >= 5 can be written in a nontrivial way as p = Sum (b_i)^2 such that Sum (b_i)^4 is also prime. This sequence lists the number of required terms b_i for each prime. The two initial zeros say that this decomposition is not possible for prime(1) = 2 and prime(2) = 3, and are thus conjectured to be the only zeros of the sequence. Since we are interested in the minimal number of terms, we can consider only nonzero b_i >= 1 and min{b_i} >= 2 to avoid the trivial solution b_i = 1 for all i <= k = prime(n).

V3-013260 | OEIS-A305310

Numbers k(n) used for Cassels's Markoff forms MF(n) corresponding to the conjectured unique Markoff triples MT(n) with maximal entry m(n) = A002559(n), for n >= 1.

Numbers k(n) used for Cassels's Markoff forms MF(n) corresponding to the conjectured unique Markoff triples MT(n) with maximal entry m(n) = A002559(n), for n >= 1. Every m(n) is proved to appear as largest member of a Markoff triple MT(n) = (m_1(n), m_2(n), m(n)), with positive integers m_1(n) < m_2(n) < m(n) for n >= 3 (MT(1) = (1, 1, 1) and MT(2) = (1, 1, 2)) satisfying the Markoff equation m_1(n)^2 + m_2(n)^2 + m(n)^2 = 3*m_1(n)*m_2(n)*m(n). The famous Markoff uniqueness conjecture is that m(n) as largest member determines exactly one ordered triple MT(n). See, e.g., the Aigner reference, pp. 38-39, and Corollary 3.5, p. 48. [In numerating the sequence with n related to A002559(n) this conjecture is assumed to be true. - _Wolfdieter Lang_, Jul 29 2018] a(n) = k(n) has been defined in terms of the (conjectured unique) ordered Markoff triple MT(n) = (m_1(n), m_2(n), m(n)) with m(n) = A002559(n) in the comment above as k(n) = min{k1(n), k2(n)}, where m_1(n)*k1(n) - m_2(n) == 0 (mod m(n)), with 0 <= k1(n) < m(n), and m_2(n)*k2(n) - m_1(n) == 0 (mod m(n)), with 0 <= k2(n) < m(n).

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013262 | OEIS-A305312

Discriminant a(n) of the indefinite binary quadratic Markoff form m(n)*F_{m(n)}(x, y) with m(n) = A002559(n), for n >= 1.

a(n) is also the discriminant D(n) = a(n) of the indefinite binary quadratic form determining the Markoff triple MT(n) = (x(n), y(n), m(n)) if the largest member is m(n) = A002559(n) and x(n) <= y(n) <= m(n). This is the form x^2 - 3*m*x*y + y^2 = -m^2 (with dropped argument n), or in reduced version X^2 + b*X*Y - b*Y^2 = -m^2, with b = b(n) = 3*m(n) - 2, where X = X(n) = y(n) - x(n) and Y = Y(n) = y(n). The uniqueness of such Markoff triples MT(n) with given largest members m(n) is a conjecture. If the forms for a Markoff triple with largest member m are numerated with n giving m as m(n) = A002559(n)as in the present entry then the uniqueness conjecture is assumed to be true. Otherwise certain m(n) will lead to several different forms. - _Wolfdieter Lang_, Jul 30 2018

V3-013263 | OEIS-A305313

Smallest member m_1(n) of the ordered Markoff triple MT(n) with largest member m(n) = A002559(n), n >= 1. These triples are conjectured to be unique.

Smallest member m_1(n) of the ordered Markoff triple MT(n) with largest member m(n) = A002559(n), n >= 1. These triples are conjectured to be unique. The second member m_2 of the Markoff (Markov) triple MT(n) = (m_1(n), m_2(n), m(n)) with m_1(n) <= m_2(n) <= m(n), for n >= 1, with m(n) = A002559(n) is given in A305314(n). For n>=3 the inequalities are strict. The existence of MT(n) with largest number m(n) is proved. The uniqueness is conjectured. The Markoff equation is (the argument n is dropped) m_1^2 + m_2^2 + m^2 = 3*m_1*m_2*m. See the references under A002559. a(n) = m_1(n) is the fundamental proper solution x of the indefinite binary quadratic form x^2 - 3*m(n)*x*y + y^2, of discriminant D(n) = 9*m(n)^2 - 4 = A305312(n), representing -m(n)^2, for n >= 1, with x <= y. The uniqueness conjecture means that there are no other such fundamental solutions.

V3-013265 | OEIS-A305315

a(n) = sqrt(5*b(n)^2 - 4), with b(n) = A134493(n) = Fibonacci(6*n+1), n >= 0.

This shows that ordered Markoff (Markov) triples [1, y, m], with 1 <= y <= m, have for m from the union of sets {m1(k)}_{k>=0} U {m5(k)}_{k>=0) U {m3(k)}_{k>=0)}, with mj(k) = F(6*k+j), for j = 1, 5, and 3, the unique solutions yj(k) = (3*F(6*k+j) - aj(k))/2 < mj(k), namely y1(k) = F(6*k-1) = A134497(k-1) with F(-1) = 1, y5(k) = F(6*k+3) = A134495(k) and y3(k) = F(6*k+1) = A134493. The solutions with the + sign are excluded because they are > mj(k). This trisection of the odd-indexed Fibonacci numbers as m numbers shows again the well known fact that each of them appears as largest member in a Markoff triple if the smallest member is x = 1. The positions of the odd-indexed Fibonacci numbers in the Markoff sequence A002559 are given in A158381. The conjecture in this case is that the odd-indexed Fibonacci numbers appear as largest numbers only in the ordered Markov triples with x = 1. See, e.g., the Aigner reference for the general Frobenius-Markoff conjecture.

V3-013266 | OEIS-A305317

a(n) gives the length of the period of the regular continued fraction of the quadratic irrational of any Markoff form representative Mf(n), n >= 1 (assuming the uniqueness conjecture).

a(n) gives the length of the period of the regular continued fraction of the quadratic irrational of any Markoff form representative Mf(n), n >= 1 (assuming the uniqueness conjecture). The index n enumerates the Markoff triples with largest member m from A002559 in increasing order. If the Markoff-Frobenius uniqueness conjecture (see, e.g. the book of Aigner) is true then the triples can be numbered by n if the largest member is m(n) = A002559(n). In the other (unlikely) case there may be more than one triple (hence forms) for some Markoff numbers m from A002559, and then one orders these triples lexicographically. The indefinite binary quadratic Markoff form Mf(n) = Mf(n;x,y) for the given Markoff number m(n) = A002559(n), n >= 1, (assuming that the mentioned uniqueness conjecture is true) is m(n)*x^2 + (3*m(n) - 2*k(n))*x*y + (l(n) - 3*k(n))y^2 with l(n) = (k(n)^2 +1)/m(n), and k(n) is defined for the representative form (of the unimodualar equvivalence class), e.g., in Cassels as k(n) = k_C(n) = A305310(n). The qudadratic irrational xi(n) is the solution of Mf(n;x,1) = 0 with the positive root. For the representative forms used by Cassels the regular continued fractions for xi(n) = xi_C(n) are not purely periodic. The smallest preperiod is -1 for n = 1 and 0 for n >= 2.

V3-013281 | OEIS-A305550

Expansion of e.g.f. Product_{k>=1} (1 + (exp(x) - 1)^k).

Conjecture: Let k be a positive integer. The sequence obtained by reducing a(n) modulo k is eventually periodic with the period dividing phi(k) = A000010(k). For example, modulo 16 we obtain the sequence [1, 1, 3, 3, 7, 3, 15, 11, 7, 3, 15, 11, 7, 3, 15, 11, ...], with an apparent period of 4 beginning at a(4). Cf. A167137. More generally, we conjecture that the same property holds for integer sequences having an e.g.f. of the form G(exp(x) - 1), where G(x) is an integral power series. (End)

V3-013287 | OEIS-A305827

Beastly primes with beastly prime indices, i.e., primes p such that both the decimal representation of p and the decimal representation of the index of p in A000040 contain the substring "666".

Conjecture 1: The sequence is infinite. An argument in favor of the conjecture goes as follows: Choose any sufficiently large integer i containing the substring "666". Then it seems very likely, assuming the digits of prime(i) are distributed uniformly, that prime(i) contains the substring "666" at least once. Based on that argument, one can make the following stronger conjecture: Conjecture 2: There exists an integer h such that for each i >= h, prime(A051003(i)) is a term of the sequence. This conjecture may be false if some subsequences of the primes are infinite. For example, assume A004022 is infinite. Then it seems likely that there exists a large term of that sequence whose index in A000040 contains the substring "666".

V3-013324 | OEIS-A306225

Number of ways to write n as w + x^5 + pen(y) + pen(z), where w is 0 or 1, and x,y,z are integers with x >= w and pen(y) < pen(z), and where pen(m) denotes the pentagonal number m*(3*m-1)/2.

Conjecture: a(n) > 0 for all n > 0. In other words, any positive integer can be written as the sum of two fifth powers of nonnegative integers one of which is 0 or 1, and two distinct generalized pentagonal numbers. We have verified a(n) > 0 for all n = 1..2*10^6. The conjecture implies that the set A = {x^5 + pen(y): x = 0,1,2,... and y is an integer} is an additive basis of order two (i.e., the sumset A + A coincides with {0,1,2,...}). See also A306227 for a similar conjecture.

V3-013339 | OEIS-A306334

a(n) is the number of different linear hydrocarbon molecules with n carbon atoms.

We prove _Vaclav Kotesovec_'s conjectures from the Formula section. Let M = [[0,0,1], [0,1,1], [1,1,1]], X(n) = M^(n-2), and Y(n) = M^(floor(n/2)-2) = X(floor(n/2)) (with negative powers indicating matrix inverses). Let also, t_1 = [1,1,1]^T, t_2 = [1,2,2]^T, and t_3 = [1,2,3]^T. In addition, define b(n) = (1/2)*(t_1^T X(n) t_1) and c(n) = (1/2)*(t_3^T Y(n) t_1) if n is even and = (1/2)*(t_2^T Y(n) t_1) if n is odd. We have a(n) = b(n) + c(n) for n >= 1. Since the characteristic polynomial of _Vaclav Kotesovec_'s recurrence is x^9 - 2*x^8 - 3*x^7 + 5*x^6 + x^5 + 2*x^3 - 3*x^2 - x + 1 = g(x)*g(x^2), where g(x) = x^3 - 2*x^2 - x + 1, to prove his first conjecture, it suffices to show that b(n) - 2*b(n-1) - b(n-2) + b(n-3) = 0 (whose characteristic polynomial is g(x)) and c(n) - 2*c(n-2) - c(n-4) + c(n-6) = 0 (whose characteristic polynomial is g(x^2)). Since the characteristic polynomial of _Vaclav Kotesovec_'s recurrence is g(x)*g(x^2), which is a polynomial of degree 9, the denominator of the g.f. of the sequence (a(n): n >= 1) should be x^9*g(1/x)*g(1/x^2) = (1 - 2*x - x^2 + x^3)*(1 - 2*x^2 - x^4 + x^6), as _Vaclav Kotesovec_ conjectured below. The numerator of _Vaclav Kotesovec_'s g.f. can be easily derived using the initial conditions (from a(1) = 1 to a(9) = 409). (End) Conjectures from _Vaclav Kotesovec_, Feb 12 2019: (Start) G.f.: (1 - x - 2*x^2 - x^4 + 2*x^5 + x^6 - x^7) / ((1 - 2*x - x^2 + x^3)*(1 - 2*x^2 - x^4 + x^6)) - 1. (End) [These conjectures are true. See my comments above. - _Petros Hadjicostas_, Nov 17 2019]

V3-013345 | OEIS-A306384

Start with n and repeatedly double it and apply the "delete any run of identical digits" operation described in A321801; a(n) is the number of steps needed to reach one of 0, 1, or 5, or -1 if none of these three numbers is ever reached.

Conjecture: every number will eventually reach one of 0, 1, or 5. Conjecture is true for n < 10^10.

V3-013350 | OEIS-A306460

Number of ways to write n as x*(2x-1) + y*(y+1)/2 + z*(z+1)*(z+2)/6, where x,y,z are nonnegative integers with x > 0.

Conjecture 1: a(n) > 0 for all n > 0. In other words, any positive integer n can be written as the sum of a positive hexagonal number, a triangular number and a tetrahedral number. Conjecture 2: Let c be 1 or 3. Then each n = 0,1,... can be written as c*x(x+1) + y*(y+1)/2 + z*(z+1)*(z+2)/6 with x,y,z nonnegative integers. Conjecture 3: Let t(x) = x*(x+1)*(x+2)/6. Then each n = 0,1,... can be written as 2*t(w) + t(x) + t(y) + t(z) with w,x,y,z nonnegative integers. We have verified Conjecture 3 for all n = 0..2*10^5. Clearly, Conjecture 3 implies Pollock's conjecture which states that any natural number is the sum of five tetrahedral numbers.

V3-013354 | OEIS-A306516

a(n) is the decimal representation of the binary number with string structure 10s00, s in {0,1}*, such that it results in a non-palindromic cycle of length 4 in the Reverse and Add! procedure in base 2 and is not in the trajectory of any m < a(n).

It is conjectured that all terms in this sequence are derived from S -> S_a -> 10 T_a 00 -> 10 T_a0 00 (in decimal representation here) when we represent the cyclic patterns by the context-free grammar with production rules: It is observed that numbers of the form 81*2^k + 2^floor((k+6)/2) + 2^6*(2^floor((k-8)/2) - 1) + 4 for k >= 11 (i.e. numbers lower(k) as defined in A306514) are all included in this sequence. By assuming this conjecture is true, it is easily to see that the number of seeds for the Reverse and Add! are infinite in base 2.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _A.H.M. Smeets_, Feb 21 2019 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-013355 | OEIS-A306517

a(n) is the binary number with string structure 10s00, s in {0,1}*, such that it results in a non-palindromic cycle of length 4 in the Reverse and Add! procedure in base 2 and is not in the trajectory of any m < a(n).

It is conjectured that all terms in this sequence are derived from S -> S_a -> 10 T_a 00 -> 10 T_a0 00 when we represent the cyclic patterns by the context-free grammar with production rules: It is observed that all strings 10 T_a0 00, with T_a0 produced by the extended right regular grammar with starting symbol T_a0 and production rules T_a0 -> 1010010 T_a0 | 101, are included in this sequence; i.e. the set of seeds in base 2 is infinite if this conjecture is true. Similar observations can be made for any base b = 2^a, a > 0.

V3-013359 | OEIS-A306559

A self-describing sequence mostly made of 1's and 0's emerging when written in English words (see the Comments section for an explanation).

Jean-Marc Falcoz has computed 100000 terms and found no place where the sequence enters into a loop. It is conjectured that the sequence will grow infinitely without ever entering into such a loop. The proportions of ONEs and ZEROs are conjectured to be 2/3 and 1/3. _Alan C. Wechsler_ (Feb 23 2019) observes that if the first four terms are deleted, this appears to coincide with A039982. Indeed, the resulting pair of sequences agree for at least the first 28442 terms, so this is a very plausible conjecture. - _N. J. A. Sloane_, Feb 23 2019 After deleting the first three terms, this sequence is 0*W(0)*W^2(0)*W^3(0)*... where W is the morphism 0 -> 11, 1 -> 01. It can be shown that this is equivalent to the above conjecture (see link for proof). - _Charlie Neder_, Mar 04 2019

V3-013373 | OEIS-A306761

Let digsum(k) = A007953(k) denote the digital sum of k. The sequence lists the smallest integer k such that digsum(k) = digsum (k/d(1)) = digsum (k/d(2)) = ... = digsum (k/d(n)) where d(i) are the n distinct prime factors of k.

Conjecture 1: a(n) == 0 (mod 54) for n > 1. Conjecture 2: a(n)/27 is a squarefree number for n > 1. The smallest multiple of 54 that can be a(10) is 1069808930190, which is also a multiple of 7^2, so the two conjectures above cannot be both true. - _Giovanni Resta_, Mar 08 2019

V3-013382 | OEIS-A306921

Number of ways of breaking the binary expansion of n into consecutive blocks with no leading zeros.

Conjecture: n appears A067824(n) times for n > 1. Proof: Each partition of n is uniquely determined by a partition of k (call it K) and a choice of some number, from 0 to e, of trailing digits to append to the final part in K, since any remaining digits must appear as singletons. The conjecture follows, since each ordered factorization of a number m produces two numbers n such that a(n) = m, one of each parity, and A067824(n) = 2*A074206(n).

V3-013408 | OEIS-A307486

a(0) = 3; a(n) = smallest k > 1 such that 1 + a(0)*a(1)*...*a(n-1)*k is composite.

Conjecture: for any initial term a(0) > 0, a(n) > 3 only for finitely many n >= 0. Carl Pomerance (in a letter to the author) wrote: Since the sequence a(0)a(1)...a(n-1) grows geometrically, the chance that any given k will give a prime is about 1/n, so the chance that both k = 2 and k = 3 will give primes is about 1/n^2, heuristically, which has a convergent sum. Thus, for this reason I would agree it's reasonable to conjecture that for any starting a(0), the sequence will eventually be made up of 2's and 3's, with 2's predominating. The number of 3's among the first n terms should be proportional to log n.

V3-013425 | OEIS-A307744

A fractal function, related to ruler functions and the Cantor set. a(1) = 0; for m >= 0, a(3m) = 1; for m >= 1, a(3m-1) = a(m-1) + sign(a(m-1)), a(3m+1) = a(m+1) + sign(a(m+1)).

Take a Sierpinski arrowhead curve formed of unit edges numbered consecutively from 0 at its axis of symmetry and aligned with an infinite Sierpinski gasket so that each edge is contained in the boundary of either the plane sector occupied by the gasket or a triangular region of the gasket's complement. If a(n) = 0, the n-th edge is contained in the sector boundary, otherwise the relevant triangular region seems to have side 2^(a(n)-1). See A307672 for a fuller description. The conjectured formulas below (that use A094373) derive from summing areas of regions within the gasket. - Corrected by _Peter Munn_, Aug 09 2019 Sum_{n=-3^k..3^k-1} A094373(a(n)) = 3 * 4^k (conjectured). Sum_{n=-3m..3m-1} A094373(a(n)) = 4 * Sum_{n=-m..m-1} A094373(a(n)) (conjectured).

V3-013464 | OEIS-A308190

Number of steps to reach 5 when iterating x -> A111234(x) starting at x=n.

It is easy to show that every number n >= 5 eventually reaches 5. This was conjectured by Ali Sada. For A111234 sends a composite n > 5 to a smaller number, and sends a prime > 5 to a smaller number in two steps. Furthermore no number >= 5 can reach a number less than 5. So all numbers >= 5 eventually reach 5.

V3-013533 | OEIS-A309130

Smallest prime factor of A077586(n).

a(n) = A077586(n) iff A077586(n) is prime, A077586(n) is prime for 1 <= n <= 4, but composite for 5 <= n <= 17. The status of A077586(18) = 2^(2^61-1)-1 is unknown. It is conjectured that A077586(n) is composite for all n >= 5. Conjecture: All terms are in A122094 (all terms in A263686 are in A122094). For examples related to that conjecture, see A322568. - _Jeppe Stig Nielsen_, Aug 29 2019

V3-013573 | OEIS-A309878

The real part of b(n) where b(n) = (n + b(n-1)) * (1 + i) with b(-1)=0; i = sqrt(-1).

Conjectures from _Colin Barker_, Aug 21 2019: (Start) E.g.f.: exp(x)*(-x + 2*sin(x)). - Conjectured by _Stefano Spezia_, Aug 21 2019 after _Colin Barker_ Conjecture: a(n) = 2*A009545(n)-n. - _R. J. Mathar_, Mar 06 2022 All conjectures stated above hold true. See links. - _Sela Fried_, Jul 27 2024.

V3-013575 | OEIS-A309906

a(n) is the smallest number of divisors of p^n - 1 that may possibly occur for arbitrarily large primes p.

The existence of infinitely many primes p such that p^n - 1 has exactly a(n) divisors is conjectured. E.g., although it is known that p-1 has fewer than 4 divisors for only finitely many primes p (see Example section), it is not known whether there exist infinitely many primes p such that p-1 has exactly 4 divisors. (Thanks to _Jianing Song_, who pointed out the need for this clarification.) - _Jon E. Schoenfield_, Mar 04 2021

V3-013577 | OEIS-A309985

Maximum determinant of an n X n Latin square.

a(10) = 36843728625, conjectured. See Stack Exchange link. - _Hugo Pfoertner_, Sep 29 2019 The conjectured value a(10) = 36843728625 above is false. The noncirculant Latin square in the Example section has absolute determinant 36860608125. Therefore a(10) >= 36860608125 > A328030(10) = 36843728625, and the maximum absolute determinant at order 10 cannot be attained by a circulant Latin square. - _Arthur Queiroz M._, Aug 06 2026

V3-014025 | OEIS-A318921

In binary expansion of n, delete one symbol from each run. Set a(n)=0 if the result is the empty string.

Conjecture: For n in the range 2^k, ..., 2^(k+1)-1, the total value of a(n) appears to be 2*3^(k-1) - 2^(k-1) (see A027649), and so the average value of a(n) appears to be (3/2)^(k-1) - 1/2. - _N. J. A. Sloane_, Sep 25 2018 The above conjecture was proved by _Doron Zeilberger_ on Nov 16 2018 (see link) and independently by _Chai Wah Wu_ on Nov 18 2018 (see below). - _N. J. A. Sloane_, Nov 20 2018 Conjecture is correct for k > 0. Proof: looking at the least significant 2 bits of n, it is easy to see that a(4n) = 2a(2n), a(4n+1) = a(2n), a(4n+2) = a(2n+1) and a(4n+3) = 2a(2n+1)+1. Define f(k) = Sum_{i=2^k..2^(k+1)-1} a(i), i.e. the sum ranges over all numbers with a (k+1)-bit binary expansion. Thus f(0) = a(1) = 0 and f(1) = a(2)+a(3) = 1. By summing over the recurrence relations for a(n), we get f(k+2) = Sum_{i=2^k..2^(k+1)-1} (f(4i) + f(4i+1) + f(4i+2) + f(4i+3)) = Sum_{i=2^k..2^(k+1)-1} (3a(2i) + 3a(2i+1) + 1) = 3*f(k+1) + 2^k. Solving this first order recurrence relation with the initial condition f(1) = 1 shows that f(k) = 2*3^(k-1)-2^(k-1) for k > 0.

V3-014037 | OEIS-A319197

All entries from a(3) to a(n) appear in addition to 2^n as factors in the conjectured factorization of Fibonacci(2^(n-2)*3*m) for n >= 3 and all m >= 0.

All entries from a(3) to a(n) appear in addition to 2^n as factors in the conjectured factorization of Fibonacci(2^(n-2)*3*m) for n >= 3 and all m >= 0. It appears that Fibonacci(2^(n-2)*3*m)/(2^n) is a nonnegative integer for n >= 3 and all m >= 0. The remaining factor for n >= 3 is given by A(n) := Product_{j=3..n} a(j). For n = 3 and 4 see A049660 and A253368, respectively. Thus the conjecture is that I(n; m) := Fibonacci(2^(n-2)*3*m) / ((2^n)*A(n)) is a nonnegative integer for all m >= 0. This is best possible for all m (because for m = 1 this becomes 1); special m may allow more factors. E.g., n = 3: 8 | Fibonacci(6*m), for all m >= 0, but for even m larger powers of 2 than 2^3 appear; for m = 0 any power of 2. I(n; m) := F(2^(n-2)*3*m) / ((2^n)* Product_{j=3..n} a(j)) is conjectured to be a nonnegative integer for n >= 3 and all m >= 0, where F = A000045. There are no more factors > 1 for all m >= 0 because I(n, 1) = 1.

First differences of the tribonacci representation numbers (A003726 or A278038).

Conjecture: All terms are of the form ceiling(2^k/7) for some k (cf. A046630), and all numbers of the form ceiling(2^k/7) occur. Conjecture (continued): Furthermore, new values of ceiling(2^k/7) (that is, new records) appear at n = 0, 6,12, 23, 43, 80, 148, 273, ..., which (apart from the start) are the tribonacci numbers minus 1, A000073 - 1, or A089068.

V3-014049 | OEIS-A319515

Second term of the simple continued fraction of (Sum_{k=1..n} k^k)/(n^n).

Ignoring the first two terms, a(n+1) is very similar to floor(n*e) (the Beatty sequence for e, A022843). This breaks down at n=11, where a(12)=30 and floor(11*e)=29. The successive terms (or partial denominators) in the sequence differ by 3 except for semi-regular "glitches". For example, the pattern of differences is 3132333233323332332333233

233323332332333233233323332333233233233233332... A natural conjecture is that the mean of these differences is asymptotic to e. The glitches are positioned between terms n and n+1, for values of n which begin 2,4,8,12,16,19,23,26,30,34,37,41,44,48,.... If one counts the 3's immediately preceding the 2's in the pattern of differences, one gets the "derivative" sequence 233323233232323323....

V3-014059 | OEIS-A319926

Isomer counts of compound perfect squared squares.

The isomer count of a compound perfect squared square (CPSS) is the number of ways its squared subrectangle and constituent squares can be arranged, up to symmetry of the CPSS. A squared square is perfect if none of its constituent squares are the same size. A squared square is compound if it contains a smaller squared subrectangle. Note that the squared subrectangle can be a squared square. Specific concrete examples of CPSSs with isomer counts under 100 of 4, 7, 8, 11, 12, 16, 19, 20, 23, 24, 28, 31, 32, 35, 36, 39, 40, 47, 48, 56, 60, 63, 64, 68, 72, 76, 80, 88 and 96 exist. Geometric constructions based on a suitable pair of perfect squared rectangles each with up to 4 isomers suggests additional isomer counts up to 100 of 14, 21, 22, 33, 42, 44, 66 and 99, but no actual examples are known. As the

number of squares in a squared square - the order - increases new arrangements appear. It is conjectured that expected CPSS subrectangle isomer arrangements will eventually appear if the order is high enough.

V3-014101 | OEIS-A321005

Let p = prime(n); a(n) = number of pairs of primes (i,j) with i < j < p such that i*j == 1 (mod p).

See link for conjectured asymptotic behavior of this sequence, showing (red line) first asymptotic term and residual bounds (blue lines). It appears that a(n) ~ Li(p)^2/(2*p), based upon the assumption that the probabilities that the first and second numbers in a pair are primes are independent. The residuals (with minor exceptions for some small p) seem to be bounded by (2/Pi^2)*sqrt(p). These observations were contributed by Karl Love (via Mapleprimes). - _David James Sycamore_, Nov 05 2018 An alternative heuristic argument leads the conjecture that a(n) ~ (n-4)/(2*log(n)) ~ Pi(n)/2. (Essentially the same as Karl Love's conjecture in the Comments section, but simpler to calculate.) - _N. J. A. Sloane_, Nov 06 2018

V3-014110 | OEIS-A321252

(Conjecturally) the lexicographically earliest infinite sequence over {0,1,2,3} avoiding abelian squares.

(Conjecturally) the lexicographically earliest infinite sequence over {0,1,2,3} avoiding abelian squares. An abelian square is a nonempty string where the second half is a rearrangement of the first half, like the English word "reappear". To "avoid" an abelian square means to have no contiguous block of that form. Although an easy compactness argument, combined with a result of Keränen (1992) shows that the lexicographically earliest infinite string avoiding abelian squares over the alphabet {0,1,2,3} must exist, the terms provided are only conjecturally part of the described sequence, because we have no proof currently that this particular string can be extended infinitely far to the right.

V3-014124 | OEIS-A321612

Numbers k such that all k - t are triangular numbers where t is a triangular number in range k/2 <= t < k.

This sequence is analogous to A320447. Instead of the sequence of primes it uses the sequence of triangular numbers (A000217). It is conjectured that the sequence is finite and full.

V3-014126 | OEIS-A321616

Primes p = k^2 + (k-1)^2 such that k^p - (k-1)^p is prime.

Conjecture: generally, these are primes p = a^2 + b^2 with a > b > 0 such that (a^p - b^p)/(a-b) is prime, so must be a-b = 1. It seems that there are no primes (a^q + b^q)/(a+b) for primes q = a^2 + b^2 > 5. Especially, there are probably no primes q = m^2 + 1 > 5 such that (m^q - 1)/(m-1) is prime or (m^q + 1)/(m+1) is prime. How to prove it?

V3-014144 | OEIS-A322004

Index i of the smallest Fibonacci number > n such that Fib(i) - n is a prime, or 0 if no such index exists.

Motivated by a recent "conjecture" seen on internet, that any number > 1 is of the form prime(i) + Fib(j) + Fib(k). Actually the number of such representations increases that fast that this conjecture seems not interesting. The present sequence shows that any number is the difference of a Fibonacci number and a prime, or such that n + some prime = some Fibonacci number. (See A322005 for the corresponding prime.) Most of the terms correspond to the index of the smallest Fibonacci number > n or the subsequent one. Local maxima and/or a(n) > a(n+1) + 1 correspond to numbers for which one has to look further. a(25) = 102 is a noteworthy example.

V3-014147 | OEIS-A322041

Triangle read by rows: let E denote the standard triangular 6-valent grid in the plane, regarded as a graph with the Eisenstein integers as vertices; row n gives the coordination sequence of the quotient graph E/nE.

When E is regarded as a lattice in R^2, E/nE has packing radius roughly n/2, but covering radius roughly n/sqrt(3) > n/2 (see Conway-Sloane, Chapter 4). This means that as n increases, the number of terms in the n-th row of the triangle will increase linearly with n. The largest k such that T(n,k) is nonzero is A322042(n), which is conjecturally n - ceiling(n/3). One can now formulate a specific conjecture for what row n is, for each of the six residue classes of n mod 6. There are similar conjectures for n = 6t+1, ..., 6t+5.

V3-014163 | OEIS-A322165

Numbers k that give record values for s(k)*phi(k)/k^2, where s(k) is the sum of squares of the differences between consecutive totatives of k (A322144).

Erdős conjectured that this ratio is bounded and offered $500 for a proof. The conjecture was proved by Montgomery and Vaughan, who won the prize.

V3-014164 | OEIS-A322210

G.f.: P(x,y) = Product_{n>=1} 1/(1 - (x^n + y^n)), where P(x,y) = Sum_{n>=0} Sum_{k>=0} T(n,k) * x^n*y^k, as a square table of coefficients T(n,k) read by antidiagonals.

Conjecture 1: the triangular table T(n,k) is the number of ways to form the subsum k from the partitions of n, where n and k are integers such that 0 <= k <= n. For example, t(4,2)=10; the five partitions of 4 are (4), (3,1), (2,2), (2,1,1), (1,1,1,1) with subsum 2 occurring {0,0,2,2,6) times for a total of 10. - _George Beck_, Jan 03 2020 Conjecture 2: the square table T(n,k) is the coefficient of s_lambda in the sum over all partitions lambda |-n and nu |-k of (s_rho/mu) where s_lambda*s_mu = Sum(rho|-n+k; C(rho, lambda, mu) s_rho). Simply stated as: multiply lambda with mu, and, for each term in the result, take the skew Schur function with mu and count how often you get the original lambda back. Sum up over all lambda and mu of the size n and k. Conjecture 3: the triangular table T(n,k) is analogous to conjecture 2, but counting s_lambda in s_(lambda/mu) * s_mu with lambda |-n and mu |- k and 0<=k<=n. (End)

V3-014165 | OEIS-A322253

Number of circular permutations of the integers from 0 to n which generate a complete stepping-on sequence, when the stepping-on direction depends on the odd/even parity of the current value.

It is conjectured that the sequence continues indefinitely. For the complementary case where stepping-on is always in the same direction, no permutation of 0 to n with n even can generate a complete sequence. For odd n, the number of complete sequences corresponds to A141599((n + 1)/2) for n up to 11, as limited by available computing power - it is conjectured that this correspondence continues indefinitely. - _Ian Duff_, Dec 25 2018

V3-014172 | OEIS-A322523

a(n) is the least nonnegative integer k for which there does not exist i < j with i+j=n and a(i)=a(j)=k.

Proof is based on induction on n. Obviously a(n) != 0. For 1 <= e <= a(n/3), there exists i+j = n/3, i < j such that a(i) = a(j) = e-1, by induction hypothesis we have a(3*i) = a(3*j) = e, so a(n) != e. a(n) = a(n/3) + 1 is OK. Suppose otherwise that n = i+j, i < j and a(i) = a(j) = a(n/3) + 1 > 0, then i,j == 0 (mod 3), by induction hypothesis we have a(i/3) = a(j/3) = a(n/3), a contradiction. Obviously a(n) != 0. From (1) we know that a(3^e) = a(2*3^e) = t. For 1 <= e <= t, n - d_e*3^e = 3*(Sum_{0<=r<=t-1, r!=e-1} d_r*3^r + O(3^(t+1))) + 5 = 3*(Sum_{0<=r<=e-2} d_r*3^r + O(3^e)) + 5, so A215879((n-d_e*3^e-5)/3) = e-1. Since 5 <= n - d_e*3^e == 2 (mod 3), by induction hypothesis we have a(n-d_e*3^e) = e = a(d_e*3^e), so a(n) != e. a(n) = t+1 is OK. Suppose otherwise that n = i+j, i != j and a(i) = a(j) = t+1 > 0, then {i,j} == {0,2} (mod 3) and i,j > 2. Suppose that i == 2 (mod 3), by induction hypothesis A215879((i-5)/3) = t. Write i = 3*(Sum_{0<=r<=t-1} d'_r*3^r + O(3^(t+1))) + 5, 1 <= d'_r <= d_r. If d'_r = d_r for all r, then j = n-i is divisible by 3^(t+2), so a(j) >= t+2, a contradiction. If d'_r != d_r for some r, then j = 3^(r_0+1) + O(3^(r_0+2)) where r_0 is the smallest index such that d'_r != d_r, so a(j) = r_0+1 + a(1+O(3^1)) = r_0+1 <= t, also a contradiction.

V3-014176 | OEIS-A322631

a(n) = 2*binomial(7*n-1,2*n)/(7*n-1).

In 2012, Nakamigawa and Tokushige stated: Let A[x,y] = number of lattice paths starting at (0,0) that stay in y < 2*x/5 + 2/5 and B[x,y] = number of lattice paths starting at (0,0) that stay in y < 2*x/5 + 1/5, then a(t) = A[5*t-1,2*t-1] + B[5*t-1,2*t-1]. Their theorem was mentioned by D. Knuth in Problem 4 "Lattice Paths of Slope 2/5" in his lecture "Problems That Philippe (Flajolet) Would Have Loved". Knuth reported the empirical observation that A[5*t-1,2*t-1]/B[5*t-1,2*t-1] = a - b/t + O(t^-2), with constants a~=1.63026 and b~=0.159. Knuth's conjecture was proved by C. Banderier and M. Wallner, who also found the exact values of a and b. Numerical values of a and b are provided in A322632 and A322633.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014204 | OEIS-A323739

a(n) is the number of residues modulo (4*primorial(n)) of the squares of primes greater than or equal to prime(n+1).

Conjecture: a(n) = 2^(1-n)*Product_{j=1..n} (prime(j)-1) for n >= 0, so a(n) = a(n-1)*(prime(n)-1)/2 for n >= 1. Conjecture is true. Since there exists a prime congruent to r modulo 4*primorial(n) for any r coprime to primorial(n), this set is precisely the set of coprime quadratic residues of 4*primorial(n). If n >= 1, each residue can be broken down into congruences modulo 8 and the first n-1 odd primes, each odd prime p has (p-1)/2 residue classes, and every combination eventually occurs, giving the formula. (End)

V3-014237 | OEIS-A324794

Conjectured value of N(2^n), defined by property that the Jensen polynomial J^{2^n,m}_p(X) is hyperbolic for m >= N(2^n).

Conjectured value of N(2^n), defined by property that the Jensen polynomial J^{2^n,m}_p(X) is hyperbolic for m >= N(2^n). Normally the OEIS does not list conjectured values in the Data section, but an exception has been made here in view of the importance of these numbers. The conjectured values of N(d) for d = 1,...,9 are 1, 25, 94, 206, 381, 610, 908, 1269, 1701.

V3-014238 | OEIS-A324863

Binary length of A324866(n), where A324866(n) = A156552(n) OR (A323243(n) - A156552(n)).

Provided that the maximal value that A324861(d) attains among divisors d of n is attained an odd number of times, then a(n) gives that maximal value. It is conjectured that this always holds. Among n = 1..10000, there are only two such cases, where the maximal value occurs more than once among the divisors: 3675 and 7623, where it occurs three times in both (see the examples). a(n) = Max_{d|n} A324861(d) [conjectured].

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014241 | OEIS-A324969

Number of unlabeled rooted identity trees with n vertices whose non-leaf terminal subtrees are all different.

The conjecture of Mathar is true. Proof: Given a rooted identity tree T, a terminal subtree T' with more than one vertex contains at least one edge that is also a terminal subtree of T'. Thus, if T has more than one branch with more than one vertex, then it fails the additional condition since it would have at least two non-leaf terminal subtrees (namely edges) that are the same. Also, T can't have under its root more than one branch with exactly one vertex because it is an identity tree. Now we know that under the root of T is exactly one branch of the same kind as T or else it has exactly one other branch with exactly one vertex. The leads immediately to the same recurrence as A000045 the Fibonacci sequence except for n=3. (End)

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014294 | OEIS-A326042

a(n) = A064989(sigma(A003961(n))), where A003961 shifts the prime factorization of n one step towards larger primes, and A064989 shifts it back towards smaller primes.

Conjecture: There are no other fixed points than a(1) = 1. If true, then there are no odd perfect numbers. This condition is equivalent to the condition that if A161942 has no fixed points larger than one, then there are no odd perfect numbers. This follows as whenever k is a fixed point, that is, a(k) = k, then we should also have A003961(a(k)) = A003961(A064989(sigma(A003961(k)))) = A161942(A003961(k)) = A003961(k). Note that A003961 is an injective and surjective mapping from natural numbers to odd numbers, A064989 is its (left) inverse, and composition A003961(A064989(n)) is equivalent to A000265(n).

V3-014329 | OEIS-A326896

Prime numbers p such that 0 < pi(p;10,(9,1)) = pi(p;10,(1,7)) where pi(x;q,(a,b)) is the number of primes p_n <= x such that p_n == a (mod q) and p_(n+1) == b (mod q).

Lemke Oliver and Soundararajan conjectured that pi(x;3,(1,1)) < pi(x,3,(1,2)) and pi(x;4,(1,1)) < pi(x;4,(1,3)) are robust biases, i.e., they always hold. Here we conjecture that pi(x;10,(9,1)) > pi(x;10,(1,7)) is a semi- robust bias, i.e., it holds from a certain value x_0 on. Here x_0 is conjectured to be 17839. This conjecture seems to be confirmed by the observation that pi(x;10,(9,1)) - pi(x;10,(1,7)) ~ (Li(x)/16) * (1/2) * log(2*Pi/5*log(x)) / log(x).

V3-014342 | OEIS-A327297

Terms in A003656 that are not prime powers (A246655).

Conjecture: if D is a term of this sequence, then D = uv, where u, v are 4, 8 or primes congruent to 3 modulo 4. For example, a(1) = 12 = 3*4, a(2) = 21 = 3*7, a(3) = 24 = 3*8, a(4) = 28 = 4*7, a(5) = 33 = 3*11, ... [This conjecture is correct: see Theorem 1 and Theorem 2 of Ezra Brown link; see also A003656. - _Jianing Song_, Dec 28 2021] Also, it is conjectured that the quadratic field with discriminant D has form class number 2, where D is a term of this sequence. This is equivalent to the conjecture above. [This can also be deduced from the first paragraph of Ezra Brown link: the norm of the fundamental unit of the field k is -1 if D = 8 or a prime congruent to 1 modulo 4, and 1 if D is in this sequence. Here k is the quadratic field with discriminant D. - _Jianing Song_, Dec 28 2021]

V3-014360 | OEIS-A327621

Sums of distinct powers of 3 and powers of 4 (greater than 1).

These gaps are closely related to the gaps in the set where 3^0 and 4^0 are (both) also allowed to be in the sum, in which case the first missing numbers are A367090 = (62, 63, 143, 144, 207, ...), see also Melfi's paper. It is obvious that the study of these gaps is crucial for the proof of Erdös conjecture. For A(x) the enumerating function, Erdős conjectured that A(x) > c*x.

V3-014368 | OEIS-A327883

a(0)=a(1)=0; thereafter a(n+1) is the index of the earliest as yet unused occurrence of a(n) if a(n) has occurred before; otherwise a(n+1) = a(a(n)-1). Once an occurrence of a(n) has been used it cannot be used again.

There appears to be a proper copy subsequence given by a(4*m+2) = a(m-1); m >0 (noticed by Carl J Love). There may be other (independent) copies to be found (e.g. by selecting terms sequentially, one from each of the above mentioned intervals). A family of sequences similar to this one can be described using the same rule as above, with offset k >= 0 and initial terms a(k) = a(k+1) = k. Conjecture: Every such sequence contains a proper copy of itself as a(4*m+2+k) = a(m+k-1). Conjectured formulae:

V3-014373 | OEIS-A327969

The length of a shortest path from n to zero when using the transitions x -> A003415(x) and x -> A276086(x), or -1 if no zero can ever be reached from n.

When I created this sequence, I conjectured that by applying two simple arithmetic operations "arithmetic derivative" (A003415) and "primorial base exp-function" (A276086) in some combination, and starting from any positive integer, we could always reach zero (via a prime and 1). At the first sight it seems almost certain that the conjecture holds, as it is always possible at every step to choose from two options (which very rarely meet, see A351088), leading to an exponentially growing search tree, and also because A276086 always jumps out of any dead-end path with p^p-factors (dead-end from the arithmetic derivative's point of view). However, it should be realized that one can reach the terms of either A157037 or A327978 with a single step of A003415 only from squarefree numbers (or respectively, cubefree numbers that are not multiples of 4, see A328234), and in general, because A003415 decreases the maximal exponent of the prime factorization (A051903) at most by one, if the maximal exponent in the prime factorization of n is large, there is a correspondingly long path to traverse if we take only A003415-steps in the iteration, and any step could always lead with certain probability to a p^p-number. Note that the antiderivatives of primorials with a square factor seem quite rare, see A351029. For all of the above reasons, I now conjecture that there are natural numbers from which it is not possible to reach zero with any combination of steps. For example 128 or 5^5 = 3125.

V3-014393 | OEIS-A328190

Lexicographically earliest infinite sequence of distinct positive integers such that the sequence and its first differences have no values in common.

Conjecture from _N. J. A. Sloane_, Nov 04 2019: (Start) There is a similar conjecture for A328196. Call the three sets of conjectured terms S0, S1, and S3. The terms in S0 are == 0 or 3 mod 5; those are in S1 are == 1 or 2 mod 10; and those in S3 are == 7 mod 10. So the sets are disjoint, as required by the definition. This conjecture would imply that the points a(2t) lie on a line of slope 5/4 and the points a(2t+1) on a line of slope 5/2, as conjectured by _Peter Kagey_. (End) Let us DEFINE a sequence S by the conjectured formulas given here, and a sequence T by the conjectured formulas given in A328196. Then it is not difficult to prove that the first differences of S are given by T, and that the terms of S and T are disjoint.

V3-014418 | OEIS-A328919

Smallest index m such that from the m-th term on, the sequence {sigma_k(n) mod n: k >= 0} enters into a cycle.

Conjecture: a(n) = 0 only for n = 1, 12. If {sigma_k(n) mod n: k >= 0} is purely periodic, then sigma_0(n) == sigma_psi(n)(n) (mod n). Let p be any prime divisor of n, write n = p^e*s, then sigma_0(n) = d(n) = (e+1)*d(s), sigma_psi(n)(n) == Sum_{d|n, gcd(d,p)=1} 1 = d(s) (mod p^e), d = A000005. So sigma_0(n) == sigma_psi(n)(n) (mod n) means that p^e divides e*d(s) for every p dividing n, which seems highly impossible for n > 12. Of course, this shows that a(n) cannot be 0 if n is squarefree, so a(n) = 1 for squarefree n. Every number occurs in this sequence, because a(p^e) = e for primes p. Conjecture: a(2^e) is always the earliest occurrence of e.

V3-014419 | OEIS-A328934

Nonsquarefree N such that A328919(N) = 1; nonsquarefree N such that {sigma_t(N) mod N: t >= 1} is purely periodic, while {sigma_t(N) mod N: t >= 0} is not.

If N is squarefree then A328919(N) = 1, but the converse is not true. While it is conjectured that 12 is the only N such that 0 = A328919(N) < A051903(N), there are infinitely many N such that 1 = A328919(N) < A051903(N). This shows that A051903(N) - A328919(N) is unbounded, and can take every natural number as its value for infinitely many

times. It is conjectured that the smallest N such that A328919(N) = 1 and A051903(N) = k is N = 2^(k-1)*A002110(k-1), k >= 3.

V3-014447 | OEIS-A329333

There is exactly one odd prime among the pairwise sums of any three consecutive terms: Lexicographically earliest sequence of distinct nonnegative integers with this property.

This is conjectured and designed to be a permutation of the nonnegative integers, therefore the offset is taken to be zero. Restricted to positive indices, this is a sequence of positive integers having the same property, then conjectured to be a permutation of the positive integers. (The word "odd" can be omitted in this case.) If the word "odd" is dropped from the original definition, the sequence starts (0, 1, 3, 6, 2, 7), and then continues from a(6) = 4 onward as the present sequence. This is again conjectured to be a permutation of the nonnegative integers, and a permutation of the positive integers when restricted to the domain [1..oo). The latter however no longer has the property of lexicographic minimality.

V3-014465 | OEIS-A329449

For any n >= 0, exactly four sums a(n+i) + a(n+j) are prime, for 0 <= i < j <= 3: lexicographically earliest such sequence of distinct nonnegative integers.

This map is defined with offset 0 as to have a permutation of the nonnegative integers in case each of these eventually appears, which is so far only conjectured, see below. The restriction to positive indices would then be a permutation of the positive integers, and as it happens, also the smallest one with the given property. (This is in contrast to most other cases where that one is not the restriction of the other one: see crossrefs). Concerning the existence of the sequence with infinite length: If the sequence is to be computed in a greedy manner, this means that for given P(n) := {a(n-1), a(n-2), a(n-3)} and thus 0 <= N(n) := #{ primes x + y with x, y in P(n), x < y} <= 4, we have to find a(n) such that we have exactly 4 - N(n) primes in a(n) + N(n). It is easy to prove that this is always possible when 4 - N(n) = 0 or 1. Otherwise, similar to A329452, ..., A329456, we see that P(n) is an "admissible constellation" in the sense that a(n-4) + P(n) already gave the number of primes required now. So a weaker variant of the k-tuple conjecture would ensure we can find this a(n). But the sequence need not be computable in greedy manner! That is, if ever for given P(n) no a(n) would exist such that a(n) + P(n) contains 4 - N(n) primes, this simply means that the considered value of a(n-1) (and possibly a(n-2)) was incorrect, and the next larger choice has to be made. Given this freedom, there is no doubt that this sequence is well defined up to infinity.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014468 | OEIS-A329453

There are exactly two primes in {a(n+i) + a(n+j), 0 <= i < j <= 4} for any n: lexicographically earliest such sequence of distinct nonnegative integers.

Conjectured to be a permutation of the nonnegative numbers. (Therefore the offset is chosen to have a(0) = 0. The restriction to positive indices is then a permutation of the positive integers, but not the smallest one which is A329413, conjectured.) Concerning the existence of the sequence, if the sequence is to be computed in a greedy manner, this means the following: for given n, we assume given P(n) := {a(n-1), a(n-2), a(n-3), a(n-4)} and thus S(n) := #{ primes x + y with x, y in P(n), x < y} which may equal 0, 1 or 2. We have to find a(n) such that we have exactly 2 - S(n) primes in a(n) + P(n). It is easy to prove that this is possible when 2 - S(n) is 0 or 1. When S(n) = 0, we must find two primes which are at a distance of |x - y| for some x, y in P(n). This is much weaker than to require the existence of twin primes or cousin primes etc., generally believed to hold and in part proved under hypotheses weaker than RH: First, we have the choice of several distances. Second, we don't require that there be no other primes in between. But more than that, it is not at all needed that the sequence be computable in a greedy manner! I.e., in the extremely improbable event that for some n with S(n) = 0 there might be no a(n) such that a(n) + P(n) contains 2 primes, we have infinitely many other choices for a(n-1) or even a(n-2), etc.! Given this additional freedom, the existence of a(n) for any n is beyond any doubt (and maybe not even difficult to prove, by contradiction). Concerning the conjecture that all numbers will eventually occur: if a number m never appears, this means that m + P(n) never has the required number of 2 - S(n) primes. That is, for all n such that S(n) = 2, the set m + P(n) has at least one prime, and whenever S(n) = 1, the

set m + P(n) has never exactly 1 prime. Given that each of the sets P(n) contains 4 numbers which were chosen essentially independently of m, it appears extremely improbable that all these infinitely many constraints could hold simultaneously for any m. Computational results so far also give only strong evidence in favor of this conjecture.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _M. F. Hasler_, based on an idea from _Eric Angelini_, Nov 15 2019 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014469 | OEIS-A329454

There are exactly three primes among a(n+i) + a(n+j), 0 <= i < j <= 3, for any n >= 0: lexicographically earliest such sequence of distinct nonnegative integers.

Concerning the existence of the sequence: If the sequence is to be computed in a greedy manner, this means that for given n, we assume given P(n) := {a(n-1), a(n-2), a(n-3)} and thus S(n) := #{ primes x + y with x, y in P(n), x < y} which may equal 0, 1, 2 or 3. We have to find a(n) such that we have exactly 3 - S(n) primes in a(n) + P(n). It is easy to prove that this is always possible when 3 - S(n) is 0 or 1, and similar to the case of A329452 and A329453 when S(n) = 1. When S(n) = 0, however, we must find three primes in the same configuration as the elements of P(n). It is almost surprising that this can always be found up to n = 10^6. However, the sequence does not need to be computable in a greedy manner. That is, if for given P(n) no a(n) would exist such that a(n) + P(n) contains 3 - S(n) primes, this simply means that the considered value of a(n-1) was incorrect, and the next larger choice has to be made. Given this freedom, well-definedness of this sequence up to infinity is far more probable than, for example, the k-tuple conjecture.

V3-014470 | OEIS-A329455

There are exactly three primes in {a(n+i) + a(n+j), 0 <= i < j <= 4} for any n >= 0: lexicographically earliest such sequence of distinct nonnegative integers.

Concerning the existence of the sequence: If the sequence is to be computed in a greedy manner, this means that for given n, we assume given P(n) := {a(n-1), a(n-2), a(n-3), a(n-4)} and thus S(n) := #{ primes x + y with x, y in P(n), x < y} which may equal 0, 1, 2 or 3. We have to find a(n) such that we have exactly 3 - S(n) primes in a(n) + P(n). It is easy to prove that this is always possible when 3 - S(n) = 0 or 1, and for S(n) = 0 or 1, this is similar to the case of A329452 or A329453. However, the sequence does not need to be computable in a greedy manner. That is, if for given P(n) no a(n) would exist such that a(n) + P(n) contains 3 - S(n) primes, this simply means that the considered value of a(n-1) was incorrect, and the next larger choice has to be made. Given this freedom, well-definedness of this sequence up to infinity is far more probable than, for example, the k-tuple conjecture.

V3-014471 | OEIS-A329456

For any n >= 0, exactly four sums a(n+i) + a(n+j) are prime, for 0 <= i < j <= 4: lexicographically earliest such sequence of distinct nonnegative integers.

Concerning the existence of the sequence with infinite length: If the sequence is to be computed in a greedy manner, this means that for given P(n) := {a(n-1), a(n-2), a(n-3), a(n-4)} and thus N(n) := #{ primes x + y with x, y in P(n), x < y} in {0, ..., 4}, we have to find a(n) such that we have exactly 4 - N(n) primes in a(n) + N(n). It is easy to prove that this is always possible when 4 - N(n) = 0 or 1. Otherwise, similar to A329452, ..., A329455, we see that P(n) is an "admissible constellation" in the sense that a(n-5) + P(n) already gave the number of primes required now. So a (weaker) variant of the k-tuple conjecture ensures we can find this a(n). But the sequence need not be computable in greedy manner! That is, if ever for given P(n) no convenient a(n) would exist, this just means that the considered value of a(n-1) (and possibly a(n-2)) was incorrect, and the next larger choice has to be made. Given this freedom, there is no doubt that this sequence is well defined up to infinity.

V3-014472 | OEIS-A329475

a(n) = Sum_{k=0..n} C(n,k)^2*T(k)*T(n-k), where T(k) = A002426(k) is the coefficient of x^k in the expansion of (x^2+x+1)^k.

The author introduced this sequence in arXiv:1911.05456 and made the following conjecture. Conjecture: Let p be an odd prime and let S = Sum_{k=0..p-1}a(k)/(-4)^k. If p == 1 (mod 12) and p = x^2 + 9*y^2 with x and y integers, then S == 4*x^2-2*p (mod p^2). If p == 5 (mod 12) and p = x^2 + y^2 with x == y (mod 3), then S == 4*x*y (mod p^2). If p == 3 (mod 4), then S == 0 (mod p^2).

V3-014473 | OEIS-A329478

a(n) = (Sum_{k=0..n-1}(-1)^k*(15*k+8)*beta(k)*t(k))/(2*n), where beta(k) = A005258(k), and t(k) is the coefficient of x^k in the expansion of (x^2+4*x-1)^k.

Conjecture 1: (i) a(n) is an integer for each n > 0. Moreover, a(n) is odd if and only if n is a positive power of two. Conjecture 2: Let p > 5 be a prime and let S(p) = Sum_{k=0..p-1}(-1)^k*beta(k)*t(k). If p == 1,4 (mod 5) and p = x^2 + 15*y^2 (with x and y integers), then S(p) == 4*x^2-2p (mod p^2). If p == 2,8 (mod 15) and p = 3*x^2 + 5*y^2, then S(p) == 12*x^2-2p (mod p^2). If Leg(-15/p) = -1, then S(p) == 0 (mod p^2).

V3-014490 | OEIS-A329649

Let D = A042948(n) be the n-th positive integer congruent to 0 or 1 mod 4, then a(n) = b(D) := Sum_{i=1..D} Kronecker(D,i)*i^2, where Kronecker(D,i) is the Kronecker symbol.

Conjecture (a): There are no 0's in this sequence. Conjecture (b): if D is not of the form k^2 or 5*k^2 or 2^t (t odd, t > 1), then b(D) is divisible by 4*D; if D = 5*k^2, then b(D) is divisible by 4*k^2 = 4*(D/5). Conjecture (c): let D be a fundamental discriminant > 1 (A003658), then Sum_{k>=1} Kronecker(D,k)/k^2 = Pi^2*b(D)/D^(5/2) = (4*Pi^2)/D^(3/2) * (b(D)/(4*D)), which is an integer times (4*Pi^2)/D^(3/2) if D > 8 by the conjecture (b). Here Sum_{k>=1} Kronecker(D,k)/k^2 is the value of the Dirichlet L-series of a non-principal character modulo D at s=2.

V3-014491 | OEIS-A329654

a(n) = numerator(b(n)), where b(0) = b(1) = 1 and b(n) = n*b(n-1)/b(n-2) for n >= 1.

This sequence is derived from a particular case of a general recurrence relation expressed by B(0) = x, B(1) = y and B(n) = n*B(n-1)/B(n-2), for n > 1 and {x,y} any pair of nonzero real numbers. Scatter plots of sequences of this kind exhibit a particular pattern that suggests the following conjecture: This means that B(n)/n approaches a cycle of six different constant values which depend on the particular chosen seed {x,y}. In this particular case the seed is {1,1} and the corresponding conjectured constant limits {C_1, C_2, C_3, C_4, C_5, C_6} are approximately {0.431, 0.615, 1.426, 2.319, 1.626, 0.701}. The corresponding constant limits for a generic seed {x,y} are respectively {C_1*y, C_2*y/x, C_3/x, C_4/y, C_5*x/y, C_6*x}. If x and y are not both positive then four of these constants are negative and two are positive.

a(n) is the smallest integer k > 1 such that k cannot be expressed as a sum of distinct earlier terms nor is a multiple of any earlier term.

Conjecture: Composite terms k greater than 25 will have either two or six nontrivial divisors (that is, divisors d with 1 < d < k).

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014511 | OEIS-A330191

For -d == 0, 1 (mod 4), let E(-d) to be the exponent of the class group of binary quadratic forms with discriminant -d, b(-d) to be the smallest prime p such that Kronecker(-d,p) = 1, then sequence gives d such that E(-d) > 2 and b(-d) > sqrt(d/4).

For -d == 0, 1 (mod 4), we want to determine the size of b(-d). Let R = Z[sqrt(-d)/2] if -d == 0 (mod 4), R = Z[(1+sqrt(-d))/2)] otherwise, note that R is not necessarily a Dedekind domain. It is conjectured that if Kronecker(-d,p) = 1, then p*R is the product of two distinct prime ideals of R (this is obviously true if -d is a fundamental discriminant). It also seems that if p*R = I*I', then I^(k*e) must be principal, e = E(-d) (again, this is true if -d is fundamental). If these statements are indeed true, let t*O_k = I^(k*e), then t/p is not in R, and the norm of t over R is p^e. Define f(x,y) = x^2 + (d/4)*y^2 if -d == 0 (mod 4), x^2 + x*y + ((d+1)/4)*y^2 otherwise, it is easy to see f(x,y) = p^(k*e) has integral solutions (x,y) such that gcd(x,y) = 1. Note that 7392 is conjectured to be the largest term in A003171. Therefore, it seems that b(-d) < sqrt(d/4) for all d > 7392.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014512 | OEIS-A330221

Numbers d such that -d is a fundamental discriminant and all primes smaller than 2*sqrt(d)/Pi ramify or remain inert in the ring of integers of Q(sqrt(-d)).

But there are other d such that the ideal class group of O_K has exponent 2. In fact, the exponent is <= 2 if and only if: for all primes p < 2*sqrt(d)/Pi, either (a) Kronecker(-d,p) = 0 or -1, or (b) Kronecker(-d,p) = 1, and 4*p^2 - d is a square. Here 2*sqrt(d)/Pi can be replaced by sqrt(d); conjecturally, if 2*sqrt(d)/Pi is replaced by sqrt(d/4), we get exactly the sequence A003644.

V3-014518 | OEIS-A330358

a(n) = n mod 5 + n mod 25 + ... + n mod 5^k, where 5^k <= n < 5^(k+1).

Conjecture: For b >= 2, consider the function s(n,b) = Sum_{1 <= b^j <= n} (n mod b^j) from p. 8 in Dearden et al. (2011). Then s(b*n + r, b) = b*s(n,b) + r*N(n,b) for 0 <= r <= b-1, where N(n,b) = floor(log_b(n)) + 1 is the number of digits in the base-b representation of n. As initial conditions, we have s(n,b) = 0 for 1 <= n <= b. (This is a generalization of a result by _Robert Israel_ in A049802.) If A_b(x) = Sum_{n >= 1} s(n,b)*x^n is the g.f. of the sequence (s(n,b): n >= 1) and the above conjecture is correct, then it can be proved that A_b(x) = b * A_b(x^b) * (1-x^b)/(1-x) + x * ((b-1)*x^b - b*x^(b-1) + 1)/((1-x)^2 * (1-x^b)) * Sum_{k >= 1} x^(b^k). Conjecture: a(5*n+r) = 5*a(n) + r*A110592(n) = 5*a(n) + r*(floor(log_5(n)) + 1) for n >= 1 and r = 0, 1, 2, 3, 4. If the conjecture above is true, the g.f. A(x) satisfies A(x) = 5*(1 + x + x^2 + x^3 + x^4)*A(x^5) + x*(1 + 2*x + 3*x^2 + 4*x^3)/(1 - x^5) * Sum_{k >= 1} x^(5^k).

V3-014542 | OEIS-A330777

Numbers k such that k and Lucas(k) have the same number of divisors.

Conjecture: all terms are of the form 2^k*p for k >= 0 and p prime.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Chai Wah Wu_, Dec 31 2019 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014543 | OEIS-A330807

a(1) = 2; a(n+1) = Sum_{k=1..n} {S(a(k)): S(a(k)) = S(a(n))}, where S is sopfr (A001414).

The primes do not appear in their natural order (e.g., 31 precedes 29). If the lesser of twin primes p is a(k) and the greater twin has not already occurred, then a(k+2) is the greater twin. Whereas if a composite number appears, it may appear more than once, a prime > 2, if it appears, can appear once only. Open question: Do all primes (except for 3) eventually appear?

a(0) = 1; a(n) = Sum_{k=1..n} (-1)^(n - k) * binomial(n,k) * a(k-1) * a(n-k).

Conjecture: the e.g.f. of this sequence is the inverse function of y = x - 1/x - log(x) in a neighborhood of x = 1 on the complex plane, and its convergence radius is sqrt(3) - Pi/3 = 0.6848532563... - _Jianing Song_, Sep 30 2024

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Ilya Gutkovskiy_, Jan 16 2020 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-014566 | OEIS-A331432

Triangle T(n,k) (n >= k >= 0) read by rows: T(n,0) = (1+(-1)^n)/2; for k>=1, set T(0,k) = 0, S(n,k) = binomial(n,k)*binomial(n+k+1,k), and for n>=1, T(n,k) = S(n,k)-T(n-1,k).

For Table IV on page 93, it is simplest to ignore the minus signs. The present triangle then matches all the given terms in that triangle, so it seems best to define the triangle by the recurrences given here, and to conjecture (strongly) that this is the same as Ser's triangle.

V3-014570 | OEIS-A331506

Least primitive root g < prime(n) of the n-th prime with g a product of two Fibonacci numbers, or 0 if such a number g does not exist.

Conjecture 1: a(n) > 0 for all n > 0. In other words, for each prime p there are two Fibonacci numbers F(k) and F(m) with F(k)*F(m) < p such that F(k)*F(m) is a primitive root modulo p. It seems that Conjecture 1 can be strengthened as follows: For any prime p, there is a primitive root g < p modulo p such that g/F(2) = g or g/F(3) = g/2 or g/F(4) = g/3 is a Fibonacci number. We have verified this strong version for all primes p < 5*10^9. We also have the following conjecture similar to Conjecture 1. Conjecture 2. For any prime p, there are two Lucas numbers L(k) and L(m) with k >= m >= 0 and L(k)*L(m) < p such that L(k)*L(m) is a primitive root modulo p.

V3-014582 | OEIS-A331814

Fourier coefficients of the boundary of the Mandelbrot set (normalized by a power of two).

a(n) = 2^(2*n+1)*b(n) where b(n) is the unique sequence of complex numbers such that f(z) := z + Sum_{n>=0} (b(n)*z^-n) defines an analytic homeomorphism (biholomorphic bijection) between the complement of the unit disk and the complement of the Mandelbrot set, sometimes known as the "Jungreis function". (The b(n) are rationals, so we multiply them by the appropriate power of two to make them integers; this is equivalent to a simple rescaling of the complex plane.) It is conjectured that |b(n)| <= 1/n, so |a(n)| <= 2^(2*n+1)/n.

V3-014595 | OEIS-A332067

a(n) is the square spiral number of the initial digit of the number placed at the n-th move of the Prime scrabble game: placing integers on a grid one digit per cell as to form primes, with minus sign in case of vertical placement.

Since the numbers cannot be split (cf. rule 1), we know that a run of only d consecutive empty squares in either direction will remain empty forever once we have used all numbers < 10^d (cf. EXAMPLE). This contrasts with a variant where the numbers can be split "around" already occupied squares. In that variant one can conjecture that each square will eventually be filled.

V3-014601 | OEIS-A332215

Mersenne-prime fixing variant of A243071: a(n) = A243071(A332213(n)).

For example, for n > 1, A007814(a(n)) = A007814(n) - A209229(n), that is, this map preserves the 2-adic valuation of n, except when n is a power of two, in which cases that value is decremented by one, and in particular, a(2^k * n) = 2^k * a(n) for all n > 1. Also, like A243071, this bijection maps primes to the terms of A000225 (binary repunits). However, the "tuning" (A332213) has a specific effect that each Mersenne prime (A000668) is mapped to itself. Therefore the terms of A335431 are fixed by this map. Furthermore, I conjecture that there are no other fixed points. For the starters, see the proof in A335879, which shows that at least none of the terms of A335882 are fixed.

V3-014612 | OEIS-A332636

Two-parameter family of recursively defined triangles, T(m,t), whose rows right-padded with zeros appear in the limiting sequence of families of certain linear recursive sequences. The data presents the sequence of triangles T(2,t) by ascending antidiagonals.

The collection of k-th order recursions has a natural interpretation in terms of generalizations of the Fibonacci numbers. Define the Generalized Fibonacci numbers of order k by the recursion K(n) = Sum_{i=1..k} K(n-i), with initial conditions K(0)=0, K(i)=1, 1 <= i <= k-1. Further define G(n) = K(-n). (For k = 2, the [K(n)] are the Fibonacci numbers and for k = 3 they are the tribonacci numbers.) Then [G(n)] satisfies the recursion G(n) = G(n-k) - Sum_{i=1..k-1} G(n-k+i). (For purposes of reference later on we may suppose initial conditions G(i)=1, 1 <= i <= k-1, G(k)=0.) In other words, the recursions satisfied by the Generalized Fibonacci numbers over negative indices are

identical to the recursions we presented in this OEIS sequence above with t = 1 and m = 1 and the resulting triangle [T(i, j)] satisfies almost the same recursion as in sequence A118800 (the reason for the difference lies in the initial conditions). More precisely, the first row of the triangle [T(1, 1), T(1, 2) = [0, -(k-3)]. Boundary conditions for the rightmost and leftmost diagonals are given as follows: For i >= 1, T(i, 1) = -(2^(i-1)-1) and T(i, i+1) = (-1)^i (k-2+(-1)^i). Then for i >= 2, 2 <= j <= i, T(i, j) = 2*T(i-1, j) - T(i-1, j-1), the recursion used for the triangle in A118800 and used in this OEIS sequence for the case t = 1 and m = 1. Paul Young (see link) gives a p-adic proof of the lack of zeros among negative indices for certain Generalized Fibonacci sequences. The study presented in this OEIS sequence arose while attempting to find an inductive proof of this result which however failed. However, Hendel made the following conjecture in the problem session at West Coast Number Theory (see link). Consistent with the observations made in this OEIS sequence, when the recursion (after the initial row of length k-1) is arranged in blocks of k, then the first k-1 rows are the triangle entries right-padded with ones. It is easy to prove that these rows (for k >= 4) have no zeros. Consistent with the results in this OEIS sequence, one can show that G(k^2-1) = K(-(k^2-k-1)) = T(k-1, k). Hendel conjectured that the absolute value of G(k^2-1) or T(-(k^2-k-1)) is a minimum over the rest of the sequence, that is, |G(k^2-1)| < G(n), n >= k^2. Although it is stated on the WCNT conference that some headway had been made, these attempts failed (so the conjecture is still open). The reason for reformulating this OEIS sequence using initial conditions of mostly zeros instead of ones is that the triangle boundaries also satisfy the triangle recursion and the right-padding of zeros is more natural than the right-padding of ones.

V3-014617 | OEIS-A332843

Lexicographically earliest sequence of positive terms such that a(4n+1) is the sum of the next three terms, those three terms having the property that each of them is a substring of a(4n+1).

The sequence is infinite as one can always multiply a(4n+1) by 10 and do the same with the next three terms. It is conjectured that at least two of those three terms must be equal.

V3-014623 | OEIS-A332938

Indices of the primitive rows of the Wythoff array (A035513); see Comments.

In a row of the Wythoff array, either every two consecutive terms are relatively prime or else no two consecutive terms are relatively prime. In the first case, we call the row primitive; otherwise, the row is an integer multiple of a tail of a preceding row. Conjectures: the maximal number of consecutive primitive rows is 5, and the limiting proportion of primitive rows exists and is approximately 0.608.

V3-014627 | OEIS-A333042

G.f.: exp(Sum_{k>=1} (4*k)!/k!^4 * x^k/k).

Let A(x) denote the o.g.f. of the sequence. The sequence defined by b(n) := [x^n] A(x)^n for n >= 1 begins [24, 3672, 703968, 149835864, 33911355024, 7993981771488, 1940145241321920, ...]. We conjecture that b(n) satisfies the supercongruences b(n*p^r) == b(n*p^(r-1)) (mod p^(3*r)) for prime p >= 5 and all positive integers n and r. More generally, for a positive integer m, set A_m(x) = exp(Sum_{n >= 1} (m*n)!/(n!^m) * x^n/n) and define a sequence {b_m(n): n >= 1} by b_m(n) := [x^n] A_m(x)^n. Then we conjecture that b_m(n) is an integer sequence satisfying the same supercongruences. (End) Adamczewski includes proof abstract regarding the conjecture immediately above in linked article. - _Michael De Vlieger_, Aug 18 2026

V3-014655 | OEIS-A333515

Number of self-avoiding closed paths on an n X 5 grid which pass through four corners ((0,0), (0,4), (n-1,4), (n-1,0)).

The order-11 linear and the g.f. by _Chai Wah Wu_ are correct, for all n. Proof sketch: sweeping the n X 5 grid one row at a time, the partial cycle meets the horizontal cut between consecutive rows in a non-crossing perfect matching of the 5 active stubs; tracking this boundary-connectivity state (with union-find enforcing degree <= 2, degree exactly 2 at the four corners, no premature loop closure, no dangling end, and a single component at the final CLOSE) gives an exact integer transfer matrix M on N = 20 reachable states with a(n) = cI^T M^(n-2) v1 for n >= 2. The minimal polynomial of v1 under M is x^11 - 13*x^10 + 45*x^9 - 66*x^8 + 17*x^7 + 209*x^6 - 151*x^5 - 140*x^4 + 112*x^3 + 48*x^2 - 50*x - 28, whose annihilation q(M)v1 = 0 yields the recurrence for every n in its domain (n >= 13; i.e., n > 12); its reciprocal is exactly the conjectured denominator, and the numerator forced by a(2..12) is exactly the conjectured numerator. - _Yiming Beckmann_, Jun 06 2026

V3-014723 | OEIS-A334981

Numbers k such that the numerator of the k-th alternating harmonic number H'(k) is divisible by the square of a prime less than k.

This sequence was inspired by unsolved conjectures related to the papers by Boyd (1994) and Krattenhaler and Rivoal (2007-2009, 2009) about the harmonic numbers H(k) = Sum_{i=1..k} 1/i. See also the comments for sequences A007757, A131657, A131658, and A268112. Here we are dealing with the alternating harmonic numbers H'(k) = Sum_{i=1..k} (-1)^(i+1)/i. If variations of the above conjecture are true, then some conditional results in Krattenhaler and Rivoal (2007-2009, 2009) would hold. Boyd (1994) found only 5 integers k such that there is a prime p < k with v_p(H(k)) >= 3. Since 1994 no other k's have been found that satisfy the latter inequality. We claim that a similar conjecture holds for the alternating harmonic numbers H'(k): there is no pair of an integer k and a prime p such that v_p(H'(k)) >= 4; i.e., there is no k for which the numerator of H'(k) is divisible by the fourth power of a prime.

V3-014754 | OEIS-A335624

Number of ways to write n as x^2 + y^2 + z^2 + w^2 with x + 3*y + 4*z a square, where x, y, z, w are nonnegative integers.

Conjecture: a(n) > 0 if n is not divisible by 8. Moreover, a(n) = 0 if and only if n has the form 2^(4k+3)*m (k >= 0 and m = 1, 3, 5, 43). We have verified this for n up to 3*10^6. The conjecture is similar to the author's 1-3-5 conjecture (cf. A271518). In his 2017 JNT paper, the author conjectured that any natural number not of the form 2^(4k+2)*7 (k = 0,1,...) can be written as w^2 + x^2 + y^2 + z^2 with w + 2*x + 3*y + 5*z a square, where w, x, y, z are nonnegative integers. See also A338019 for a similar conjecture.

V3-014771 | OEIS-A335990

The moment generating function of the limiting distribution of the number of comparisons in quicksort can be written in the form M(t) = m(-2*t)/(exp(2*gamma*t)*Gamma(1 + 2*t)) for |t| < 1/2, where m(z) = Sum_{n >= 0} B(n)*z^n/n! for |z| < 1. This sequence gives the numerators of the rational numbers B(n) for n >= 0.

The formula for M(t) appears as Theorem 6.1 in Tan and Hadjicostas (1993) and derives from the work of Hennequin (1991). Hennequin conjectured a cumulant formula for the limiting distribution of the number of comparisons in quicksort in his 1989 paper, and he proved it in his 1991 thesis.

V3-014797 | OEIS-A336700

Numbers k such that the odd part of (1+k) divides (1 + odd part of sigma(k)).

Conjecture: After 1, all terms are of the form 4u+3 (in A004767). If this could be proved, then it would refute at once the existence of both the odd perfect numbers and the quasiperfect numbers. Concentrating on the latter is probably easier, as it is known that all quasiperfect numbers must be odd squares, thus k is of the form 4u+1, in which case the condition given in A336701 that A000265(1+A000265(sigma(k))) must be equal to A000265(1+k) reduces to a simpler form, A000265(1+sigma(k)) = (1+k)/2, and as k = s^2, with s odd, so (s^2 + 1)/2 should divide 1+sigma(s^2). Does that condition allow any other solutions than s=1 ? See A337339.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Antti Karttunen_, Aug 02 2020 | 2026-10-24

V3-014799 | OEIS-A336744

Integers b where the number of cycles under iteration of sum of squares of digits in base b is exactly three.

A 1978 conjecture of Hasse and Prichett describes the set L(x^2,2). New elements have been added to this set in the paper Integer Dynamics, by D. Lorenzini, M. Melistas, A. Suresh, M. Suwama, and H. Wang. It is natural to wonder whether the set L(x^2,3) is infinite. It is a folklore conjecture that L(x^2,1) = {2,4}.

V3-014803 | OEIS-A336792

Values of odd prime numbers, D, for incrementally largest values of minimal positive y satisfying the equation x^2 - D*y^2 = -2.

For solutions of this Diophantine equation it is sufficient to consider the odd primes p(n) := A007520(n), for n >= 1, the primes 3 (mod 8). Also prime 2 has the fundamental solution (x, y) = (0, 1). If there is a solution for p(n) then there is only one infinite family of solutions because there is only one representative parallel primitive binary quadratic form for Discriminant Disc = 4*p(n) and representation k = -2. Only proper solutions can occur. The conjecture is that each p(n) leads to solutions. For the fundamental solutions (with prime 2) see A339881 and A339882. - _Wolfdieter Lang_, Dec 22 2020

V3-014807 | OEIS-A336957

The Enots Wolley sequence: the lexicographically earliest infinite sequence {a(n)} of distinct positive numbers such that, for n>2, a(n) has a common factor with a(n-1) but not with a(n-2).

Conjecture 1: Every number with at least two distinct prime factors is in the sequence. In other words, apart from 1 and 2, this sequence is the complement of A000961. [It seems very likely that the arguments used to prove Theorem 1 of the Yellowstone Permutation paper can be modified to prove the conjecture.] [It appears that Conjecture 1 has been proved by Nathan Myles Nichols: see link. - _N. J. A. Sloane_, Oct 11 2026] We conjecture that even if p is introduced by some prime q>2, 2*p appears later. The differences between the two sequences are caused by the fact that although normally if p and q are odd primes with p < q, then 2p precedes 2q, this is not true for the following primes: (7,5), (31,29), and (109, 113, 107), which appear in the order shown. We conjecture that these are the only exceptions. Combining the above observations, we conjecture that for n >= 755 (at which point we have seen all the primes <= 367), every prime p is introduced by 2*p, and the terms 2*p appear in their natural order.

V3-014837 | OEIS-A337390

Expansion of sqrt((1-2*x+sqrt(1-12*x+4*x^2)) / (2 * (1-12*x+4*x^2))).

Conjecture: a(n) = [x^n] ((1 + x^2)*(1 + x)^2/(1 - x)^2)^n. Equivalently, a(n) = Sum_{k = 0..n} Sum_{j = 0..n-2*k} binomial(n,k)*binomial(2*n,j)*binomial(3*n-2*k-j-1,n-2*k-j). If the conjecture is true then the Gauss congruences a(n*p^k) == a(n*p^(k-1)) (mod p^k) hold for all primes p and positive integers n and k. Calculation suggests that the supercongruences a(n*p^k) == a(n*p^(k-1)) (mod p^(2*k)) hold for primes p >= 3 and positive integers n and k.

V3-014903 | OEIS-A338263

Number of ways to write 8*n+7 as 2*w^2 + x^2 + y^2 + z^2 with w, x, y, z nonnegative integers such that w*(3*x+7*y+10*z) is a square and also one of w, x, y, z is a square.

Conjecture 1: Each nonnegative integer can be written as 2*w^2 + x^2 + y^2 + z^2 with w, x, y, z nonnegative integers such that w*(3*x+7*y+10*z) is a square and one of w, x, y, z is also a square. As all the nonnegative integers not of the form 4^k*(8*m+7) (k>=0, m>=0) can be written as 2*0^2 + x^2 + y^2 + z^2 with x, y, z integers, Conjecture 1 has the following equivalent version: a(n) > 0 for all n = 0,1,... Conjecture 2: If (a,b) is among the ordered pairs (1,2), (1,3), (2,4), (2,5), (2,8), (2,24), (6,8), (6,32), (9,12) and (18,24), then each n = 0,1,... can be written as 2*w^2 + x^2 + y^2 + z^2 with w, x, y, z nonnegative integers such that w*(a*x+b*y) is a square.

V3-014938 | OEIS-A338751

Primes p such that (p*s) mod q and (p*s) mod r are a pair of twin primes, where q,r,s are the next primes after p.

Let g1 = q-p, g2 = r-q, g3 = s-r be the gaps between the consecutive primes p,q,r,s. Then p*s = (q-g1)*(q+g2+g3) == -g1*(g2+g3) (mod q) and similarly p*s == -(g1+g2)*g3 (mod r). According to Cramer's conjecture, g1*(g2+g3) < q and (g1+g2)*g3 < r for all but finitely many p: the only exception in this sequence appears to be p=3. When g1*(g2+g3) < q and (g1+g2)*g3 < r we have ((p*s) mod r) - ((p*s) mod q) = (r - (g1+g2)*g3) - (q - g1*(g2+g3)) = g2*(g1-g3+1). This is 2 (allowing the possibility of twin primes) if g2 = 2 and g3 = g1.

V3-014939 | OEIS-A338757

Number of splitting-simple groups of order n; number of nontrivial groups of order n that are not semidirect products of proper subgroups.

Conjecture: a(n) = 0 for squarefree n which is not a prime. The conjecture that a(n) = 0 for nonprime squarefree n is true. Proof: It is known that every group G of squarefree order is supersolvable; hence G contains a normal series with prime cyclic factors. Since every Sylow subgroup of G is prime cyclic, these cyclic factors are isomorphic to the Sylow subgroups of G. Let P be one such factor; then for an appropriate M in G, P = G/M, where |G| = |P|*|M|. By the Schur-Zassenhaus theorem, G is a semidirect product of M and P, and a(n) = 0 when n is squarefree. - _Miles Englezou_, Oct 24 2024

a(n) is the largest area of a rectangle which can be dissected into n squares with integer sides s_i, i = 1 .. n, and gcd(s_1,...,s_n) = 1.

Due to the potential counterexamples to the minimal squaring conjecture (see MathOverflow link), terms after a(19) have to be considered only as lower bounds: a(20) >= 876696755, a(21) >= 2735106696. - _Hugo Pfoertner_, Nov 17 2020, Apr 02 2021

V3-014945 | OEIS-A338926

Decimal expansion of Stechkin's constant.

Let S_m(k, q) = Sum_{j=0..q-1} e(k*j^m/q), where q>=1, m>=2, and k are integers, and e(t) = exp(2*Pi*i*t) (i is the imaginary unit). This constant is A = sup_{m,q} max_{gcd(k,q)=1} |S_m(k, q)|/q^(1-1/m). Stechkin (1975) conjectured and Shparlinskii (1991) proved that A is finite, and Banks and Shparlinski (2016) determined its value.

V3-014947 | OEIS-A338968

a(n) is the largest prime whose decimal expansion consists of the concatenation of a 1-digit prime, a 2-digit prime, a 3-digit prime, ..., and an n-digit prime.

It is a plausible conjecture that a(n) always exists and begins with 7. Conjecture: for n >= 3, a(n) is the concatenation of the largest k-digit primes with 1 <= k <= n-1: A003618(1)/A003618(2)/.../A003618(n-1) but the last concatenated prime with n digits is always < A003618(n). This conjecture has been checked by _Daniel Suteu_ until a(360), a prime with 64980 digits.

V3-014985 | OEIS-A339869

Carmichael numbers k for which A053575(k) [the odd part of phi] divides k-1.

Lehmer conjectured that the equation k * phi(n) = n - 1 (with k integer) has no solutions for any composite n (i.e., when k > 1). If this sequence has no common terms with A339818, then the conjecture certainly holds.

a(n) = 2*sigma(phi(n)) - n.

In 1964, A. Mąkowski and A. Schinzel conjectured that sigma(phi(n))/n >= 1/2 for all n (see links Mąkowski & Schinzel and Graeme L. Cohen), equivalent to a(n) >= 0. In 1992, K. Atanassov believed that he obtained a proof of this conjecture but his proof was valid only for certain special values of n (see link József Sándor).

V3-015029 | OEIS-A340511

Numbers k such that there exists a group of order k which has no subgroup of order d, for some divisor d of k.

Conjecture: If k = p^a*q^b, where p, q are primes, q !== 1 (mod p), b >= ord(q,p), then k is a term of this sequence, unless k is an NSS-CLT order of the form described in MacHale-Manning, 2016, Theorem 8, Page 5. Here ord(q,p)

is the multiplicative order of q modulo p. Moreover, if k satisfies this condition, it seems that for each NCLT group of order k, the missing orders of subgroups are of the form p^a'*q^b' where either a' = a or b' = b, and a' = a if p == 1 (mod q) or a < ord(p,q). (End)

V3-015042 | OEIS-A340757

Counterexamples to a conjecture of Ramanujan about congruences related to the partition function.

Counterexamples to a conjecture of Ramanujan about congruences related to the partition function. For b in 5,7,11, and all integers n,e >= 1, Ramanujan conjectured that if (24*n-1) is divisible by b^e, the partition function p(n) = A000041(n) is also divisible by b^e. Chowla found the first counterexample a(1) = 243. Watson showed the conjecture holds for b=5, and Atkin showed it holds for b=11. Watson showed p(n) is divisible by 7^floor((d+2)/2) when 24n-1 is divisible by 7^d, so that exceptions here are restricted to 24n-1 == 0 (mod 7^3), which is n == 243 (mod 7^3). See A340957 for the converse, those n == 243 (mod 7^3) where the conjecture does hold.

V3-015061 | OEIS-A341322

Primes p such that (p*r) == q (mod p+r) where q and r are the next primes after p.

If x = (p+r)/2 and d = (r-p)/2, p*r = x^2 - d^2 == -d^2 (mod x), while x-d < q < x+d. We can't have q = x-d^2, so it must be that q >= 2 x - d^2, and thus d^2 >= 2x-q > x-d. Cramér's conjecture implies d^2 = o(x), so that implies the sequence is finite.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015099 | OEIS-A342042

When a digit d in the digit-stream of this sequence is even, the next digit is > d.

Conjecture 1. For k >= 1, the terms of length k in S form a consecutive block with the same starting and ending points as in P. In both P and S, the block begins with 10101... (1's and 0's alternate, length is k) and end with 99...9 (k 9's). Conjecture 2. We know every number appears in S. Suppose x = S(m) = 899...9 (with k-1 9's). Then x is the last term of length k in S that begins with a digit <= 8. The remaining terms of length k have leading digit 9 and appear in order, ending with 99...9 (k 9's). Let c1 = 7.422574840... and c2 = 1.3824387... be the constants defined in A377918. Then assuming Conjecture 1, the index of the last term of length k in the present sequence is close to (c2*c1^k, 10^k). [Thanks to _Sebastian Karlsson_ for pointing out that Conjecture 1 is required and is as yet unproved.] A proof can be found in the links. Since all k-digit numbers starting with 9 appears before any (k+1)-digit number, we get that terms of a certain length form a consecutive block. In particular, this proves Conjectures 1 and 2 above.

V3-015108 | OEIS-A342171

Nonnegative integers k such that k < sec(k)*csc(k).

Conjecture: 2*k/Pi is either a little more than an even integer or a little less than an odd integer. The conjecture is true. As k > 0 increases, satisfaction of the inequality k < sec(k)*csc(k) requires that sec(k)*csc(k) be a large positive number. Since sec(k)*csc(k) = 1/(sin(k)*cos(k)) = 2/sin(2*k), this requires that sin(2*k) be a small positive number, which occurs only when 2*k/Pi is a little more than an even integer or a little less than an odd integer. - _Jon E. Schoenfield_, Mar 06 2021

V3-015111 | OEIS-A342202

T(n,k) = V(n,k)/k!, where V(n,k) = k^(n*k) - Sum_{t=1..k-1} binomial(k,t)*k^(n*(k-t))*V(n,t) for n, k >= 1; square array T read by upwards antidiagonals.

For the other compositions (s_1, ..., s_r) of k (of any size r >= 2), we group them according to the their last element s_r = s in {1, 2, ..., k - 1}, which gives rise to the factor k^(n*s)/s! = (Sum_{i=1..r} s_i)^(n*s_r)/s_r!. Using the inductive hypothesis, we substitute the expression for T(n,k-s) in the recurrence T(n,k) = k^(n*k)/k! - Sum_{s=1..k-1} k^(n*s)/s! * T(n,k-s). Each term in the expression for T(n,k-s) corresponds to a composition of k - s and is postmultiplied by k^(n*s)/s! = (Sum_{i=1..r} s_i)^(n*s_r)/s_r!. We thus get a term in the expression for T(n,k) that corresponds to a composition of the form (composition of k - s) + s, and the sign of this term is (-1)^((size of composition of k - s) + 1). The rest of the proof follows easily.

V3-015113 | OEIS-A342309

When A123556(n) is the number of primes (not necessarily consecutive) in the longest arithmetic progression of primes with common difference n, a(n) is the smallest term of the first such arithmetic progression.

About the k-tuples conjecture in A123556: let p = A053669(n), if the arithmetic progression of p elements starting at p with difference n consists of primes, then A123556(n) = p, otherwise A123556(n) = p-1. The first 21 terms of this sequence are precisely the same as A053669, then a(22) = 7 (corresponding to the arithmetic progression (7,29)) while A053669(22) = 3.

V3-015142 | OEIS-A343252

a(n) is the least k0 <= n such that v_7(n), the 7-adic order of n, can be obtained by the formula: v_7(n) = log_7(n / L_7(k0, n)), where L_7(k0, n) is the lowest common denominator of the elements of the set S_7(k0, n) = {(1/n)*binomial(n, k), with 0 < k <= k0 such that k is not divisible by 7} or 0 if no such k0 exists.

Conjecture: a(n) is the greatest power of a prime different from 7 that divides n.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015148 | OEIS-A343327

Start with a(1)=1; thereafter a(n+1) = Sum_{k=1..n such that d(a(k)) = d(a(n))} d(a(k)) where d = A000005.

Every nonzero number occurs in the sequence since all terms in A000005 are included. The multiplicity of any term m (> 2) is d(m)-1 (since m > 2 cannot be created by adding m 1s). Prime 2 occurs twice, consecutively (see example), and thereafter no two adjacent terms can be prime because the term prior to a prime q is the first occurrence of 2^(q-1) (composite for q > 2), and since d(q)=2, the following term is a multiple (> 1) of 2. Thus each prime > 2 is flanked by composite even numbers, and occurs once only. Conjecture: The primes, after the first appearance of 2, appear in their natural order.

V3-015149 | OEIS-A343368

Number of ways to write n as floor((a^3+b^3)/3) + floor((c^3+d^3)/5), where a,b,c,d are nonnegative integers with a > b and c >= d.

Conjecture 1: a(n) > 0 for all n >= 0. Conjecture 2: Each n = 0,1,... can be written as floor((a^3+b^3)/4) + floor((c^3+d^3)/5) with a,b,c,d nonnegative integers. Both conjectures have been verified for all n = 0..10^5. We also conjecture that the pair (4,5) of denominators in Conjecture 2 can be replaced by some other pairs such as (4,6), (5,6), (3,7), (4,7), (5,7), (6,7).

V3-015168 | OEIS-A343705

Numbers that are the sum of five positive cubes in exactly three ways.

It is conjectured that the number of ways of writing N as a sum of 5 positive cubes grows like C(N)*N^(2/3), where C(N) depends on N but is bounded away from zero by an absolute constant (Vaughan, 1981; Vaughan and Wooley, 2002). So the number will exceed 3 as soon as N is large enough, and so it is very likely that this sequence is finite. However, at present this is an open question. - _N. J. A. Sloane_, May 15 2021 (based on correspondence with Robert Vaughan and Trevor Wooley).

V3-015188 | OEIS-A344105

a(n) is the number of distinct numbers of transversals of order n diagonal Latin squares.

For all spectra of even orders all known values included in them are divisible by 2. For all spectra of orders n=6, n=10 and n=14 (and probably for all n=4k+2) all known values included in the corresponding spectra are divisible by 4. This leads to the following hypothesis: a(2k) <= (A287644(2k) - A287645(2k) + 2)/2 and a(4k+2) <= (A287644(4k+2) - A287645(4k+2) + 4)/4, where w(n) = A287644(n) - A287645(n) + 1 is a width of corresponding spectra and (w(n)+1)/2 is done to round the result of the division up. - _Eduard I. Vatutin_, Mar 21 2022

V3-015210 | OEIS-A344448

Square array read by antidiagonals upwards: T(n,k) for integer k >= 0 is the n-th prime p such that p^(2*3^k) + p^(3^k) + 1 is prime.

T(n,k)^(3^k), for all n >= 1, k >= 0, arranged by increasing values, is A342690. It is conjectured that all columns are infinite. If 3^k was replaced by k in the definition, all additional columns would be empty, as x^(2*k) + x^k + 1 is reducible if k has prime factors other than 3. For checking the property, Pocklington-Lehmer type primality tests seem particularly effective, as n-1 always has a large smooth factor p^(3^k), cf. the paper of Brillhart, Lehmer and Selfridge (1975), Theorem 5.

V3-015218 | OEIS-A344695

a(n) = gcd(sigma(n), psi(n)), where sigma is the sum of divisors function, A000203, and psi is the Dedekind psi function, A001615.

Conjecture: the set of primes that appear in the sequence is A065091 (the odd primes). 5 does not appear as a term until a(366025) = 5, where 366025 = 5^2 * 11^4. At this point, the missing numbers less than 22 are 2, 10 and 17. 17 appears at the latest by a(17^2 * 103^16) = 17.

V3-015259 | OEIS-A345531

Smallest prime power greater than the n-th prime.

Take the family of correlated prime-indexed conjectures appearing in A343249 - A343253, in which an alternative formula for the p-adic order of positive integers is proposed. There, the general p-indexed conjecture says that v_p(n), the p-adic order of n, is given by the formula: v_p(n) = log_p(n / L_p(k0, n)), where L_p(k0, n) is the lowest common denominator of the elements of the set S_p(k0, n) = {(1/n)*binomial(n, k), with 0 < k <= k0 such that k is not divisible by p}. Evidence suggests that the primality of p is a necessary condition in this general conjecture. So, if a composite number q is used instead of a prime p in the proposed formula for the p-adic (now, q-adic) order of n, the first counterexample (failure) is expected to occur for n = q * a(i), where i is the index of the smallest prime that divides q.

V3-015264 | OEIS-A345716

a(n) is the minimum number of nonattacking rooks required to attack every square on a size n right tetrahedral chessboard.

This sequence has been verified by brute force up to n = 27. It matches the covering numbers C(n+1, 3,2), A011975, for the first 14 terms, and it is conjectured that it matches for all even n. Link to the brute force program below. Computational runtime and increased complexity for minimum arrangements for bigger n account for the low number of terms. Other contributers: Fletcher Collins, Jennifer Gensler, Nick Jamesson, Chase Schwartzman, Evan

Young, Dr. Nat Theim. For n == 0,2 (mod 6): a(n) = n*(n+1)/6 (conjectured).

V3-015272 | OEIS-A346063

a(n) = primepi(A039634(prime(n)^2-1)).

This sequence looks at the effect on p^2 - 1 of A039634 with the primes represented by their indices. It seems that primes obtained by iterating the map A039634 on p^2 - 1 never fall into a cycle before reaching 2. Conjecture: Iterating the map k -> a(k) eventually reaches 1. For example, 1 -> 2 -> 1; 5 -> 4 -> 2 -> 1; and 27 -> 67 -> 16 -> 14 -> 4 -> 2 -> 1. If the conjecture holds, then A339991(n) != -1 and A340419 is a finite sequence.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015302 | OEIS-A346645

Mersenne prime exponents p which are twin primes, so p-2 and/or p+2 is prime.

As of July 26, 2021, the sequence of Mersenne prime exponents with a twin prime above the exponent (A087858) contains 5 terms, whereas the sequence of Mersenne prime exponents with a twin prime below the exponent (A297674) contains 12 terms, which is 2.4x as many as the former sequence. This is an empirical observation. It is uncertain whether either sequence will increase in length, but given that it is conjectured that there are infinitely many twin primes, and also conjectured there are an infinite number of Mersenne primes, both sequences may increase in length, in which case this sequence might too.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015306 | OEIS-A346695

Numbers with more divisors than digits in their binary representation.

It is natural to conjecture that this sequence has asymptotic density 0. However, after the first three terms where a(n)/n = 6 -- a function which would increase to infinity if the asymptotic density were zero -- it drops, and it seems to take a long time to get that high again. The first time it gets above 5.0 is at a(30243)=151216. Even as high as a(2188516)=10000000, the density is only ~1/4.57.

V3-015337 | OEIS-A347344

Positive integers k such that k with the first (most significant) digit repeated is prime.

Conjecture: the sequence contains infinitely many twin prime pairs (k, k+2) such that (D(k), D(k+2)) is a twin prime pair, where D(x) = x with the most significant digit repeated. The first such k is 659: both (659, 661) and (6659, 6661) are twin prime pairs. All these k begin with either 3, 6, or 9.

V3-015347 | OEIS-A347668

Indices of records in A347409.

Conjecture 1: A347409(a(n)) is even for n >= 11. Conjecture 2: all even numbers > 2 appear as A347409(a(n)) for some n. - _Chai Wah Wu_, Sep 29 2021 If conjectures 1 and 2 are true, then A347409(a(n)) = 2n - 6 for n >= 11, and hence a(n) <= (4^(n-3)-1)/3 for n >= 11 since A347409((4^(n-3)-1)/3) = 2n - 6. - _Charles R Greathouse IV_, Oct 25 2022

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Paolo Xausa_, Sep 10 2021 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015348 | OEIS-A347684

Array read by antidiagonals: T(n,k) (n>=1, k>=1) = f(n,k), where f(x,y) = x*red_inv(x,y) + y*red_inv(y,x) if gcd(x,y)=1, or 0 if gcd(x,y)>1, and red_inv is defined in the comments.

Conjecture: The entries of this array can be expressed in terms of A347683 and A347687 as follows. Write k = j*n+i, where j >= 0 and 1 <= i <= n. Then T(n,k) = A347683(n,i) + 2*n*j*A347687(n,i). For example, suppose n=3, k=11, so k = 3*3+2, with j=3, i=2. Then A347683(3,2) + 2*3*3*A347687(3,2) = 5 + 2*3*3*1 = 23, which is indeed T(3,11).

V3-015360 | OEIS-A347840

A surjective map of the positive numbers congruent to 5 modulo 8 (A004770) to the positive numbers congruent to 1, 3, or 7 modulo 8 (A047529).

This map f is of interest in the context of the Collatz 3*n+1 conjecture. The (modified) rooted tree with only odd labeled nodes has for each row k of the array A(k, m) (A347834) the same precursor (or (modified) Collatz map given in A075677(n+1), for 2*n+1). Therefore, all nodes with labels b(n) == 5 (mod 8) can be represented by a(n). This leads to a further restricted Collatz tree with only node labels congruent to {1, 3, 7} (mod 8) (A047529).

Number of ways to write n as w^2 + 2*x^2 + y^4 + 3*z^4, where w,x,y,z are nonnegative integers.

Conjecture 1: a(n) > 0 except for n = 744. Conjecture 2: For any positive odd integer a, all sufficiently large integers can be written as a*w^4 + 2*x^4 + (2*y)^2 + z^2 with w,x,y,z integers. If M(a) denotes the largest integer not of the form a*w^4 + 2*x^4 + (2*y)^2 + z^2 (with w,x,y,z integers), then M(1) = 255, M(3) = 303, M(5) = 497, M(7) = 3182, M(9) = 4748, M(11) = 5662, M(13) = 5982, M(15) = 10526, M(17) = 4028 and M(19) = 11934. Conjecture 3: Let E(a,b,c) be the set of nonnegative integers not of the form w^2 + a*x^2 + b*y^4 + c*z^4 with w,x,y,z integers. Then E(1,2,4) = {135, 190, 510}, E(1,2,5) = {35, 254, 334}, E(2,1,4) = {190, 270, 590} and E(2,3,7) = {94, 490, 983} and E(3,1,2) = {56, 168, 378}. See also A346643 and A350857 for similar conjectures.

V3-015374 | OEIS-A348168

Segment the list of prime numbers into sublists L_1, L_2, ... with L_1 = {2} and L_n = {p_1, p_2, ..., p_a(n)}, where a(n) is the largest m such that for 0 < i < m, p_1 - prevprime(p_1) > p_2 - p_1 >= p_{i+1} - p_i.

Conjecture 1: lim_{n->oo} N_i/n = k_i, where N_i is the number of the first n sublists consisting of i primes and k_i is a constant, with k_2 > k_1 > k_3 > k_4 > ... . Conjecture 2: lim_{n->oo} (Sum_{i=1..n} a(i))/n = Sum_{i=1..oo} i*k_i = e, meaning that, as n tends to infinity, the average length of sublists approaches 2.71828... (see the partial average - n plot in the links). The distribution of sublists with 1, 2, 3, 4 and 5 primes and the number of primes in the first n sublists are given in the table below. k_i's as defined in Conjecture 1 are: k1 = 0.281, k2 = 0.431, k3 = 0.127, k4 = 0.058, and k5 = 0.031, approximately. Sublists with length <= 5 account for about 93% of the terms and 70% of the primes, as n approaches infinity.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015380 | OEIS-A348299

Indices of 0 in A348295: numbers m such that Sum_{k=1..m} (-1)^(floor(k*(sqrt(2)-1))) = Sum_{k=1..m} (-1)^A097508(k) = 0.

Conjecture: sequence is infinite. Conjecture: all terms are divisible by 4. There are no counterexamples <= 10^9. Conjecture: for n >= 2, a(2n-1) = ceiling(a(n) * (3+2*sqrt(2))), a(2n) = a(2n-1) + 4. This is correct for the first 2048 terms (all terms <= 10^9). Conjectured explicit formula: if the binary expansion of n-1 is n-1 = 2^(e_0) + 2^(e_1) + ... + 2^(e_k), then a(n) = 4*(A001109(1+(e_0)) + A001109(1+(e_1)) + ... + A001109(1+(e_k))). For example, since 28-1 = 27 = 2^0 + 2^1 + 2^3 + 2^4, a(28) = 4*(A001109(1) + A001109(2) + A001109(4) + A001109(5)) = 5600.

a(1) = 1. For n >=2 the number k in n-th position becomes a(n) only if all terms a(1)..a(n-1) have already been defined, and if the smallest number m, greater than k, not already defined and sharing greatest prime factor (gpf) p with k is reduced to m/p.

Let [p] = {m: m a fixed point with gpf = p}, then [2] = {2}, [3] = {3,9,18,27}, [5] = {5,15,25,40,50,90}, etc. Every odd multiple of odd prime p, up to and including p^2, is necessarily a fixed point. The number of terms in [p] is limited by reduction of q-smooth numbers (q>p) to those having gpf p. Conjecture: For odd prime p, [p] is a finite set with greatest term > p^2, and <= p^3. A variant based on least prime divisors is also possible.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015405 | OEIS-A348970

a(n) = A003959(n) - A129283(n), where A003959 is multiplicative with a(p^e) = (p+1)^e and A129283(n) is sum of n and its arithmetic derivative.

There are no negative terms. We prove this by induction over the prime factorization of n, showing that A348507(n) >= A003415(n) for all values of n >= 1. At n=1, both sequences have value 0, and at the primes both sequences obtain the value 1, so the base cases hold. We know that A348507(n)-(n/p) = (p+1)*A348507(n/p) for all prime factors p of n (see comment in A348507). With the arithmetic derivative we obtain respectively that A003415(n) = A003415(p*(n/p)) = A003415(p)*(n/p) + p*A003415(n/p) = (n/p) + p*A003415(n/p), for any prime factor p of n. Now A348507(p*(n/p)) >= A003415(p*(n/p)) iff A348507(p*(n/p)) - (n/p) >= A003415(p*(n/p)) - (n/p), that is, iff (p+1)*A348507(n/p) >= p*A003415(n/p), which indeed follows by the induction hypothesis, which assumes that A348507(x) >= A003415(x) for all proper divisors x of n.

V3-015406 | OEIS-A349044

Non-Brauer numbers.

These differences between l^*(n) and A003313(n) are highlighted by the following formulation: consider a machine which starts with a 1 in "cache" and can then at each step execute one of two operations: (1) Add any number that has ever been in cache to the current contents of cache, or (2) Restore any number that has previously been in cache to the cache, replacing its prior contents. Then n is in this sequence if and only if there is a shortest program that results in n in cache that includes a "Restore" step. Note further that if there is an entry in this sequence such that l^*(n) > A003313(n)+1, then all shortest programs producing n in cache would contain a "Restore" operation. The definition of A293771 is based on a similar machine with a separate "Store" operation that puts the cache value into "memory," and one could formulate an analogous conjecture here that the "Restore" operation is never necessary for a shortest program. The existence or not of an n in this sequence such that l^*(n) > A003313(n)+1 would settle this question and provide mild evidence one way or the other on the conjecture in A293771.

V3-015413 | OEIS-A349272

a(n) = Product_{k = 1..2*n+1} Fibonacci(2*k) / Sum_{k = 1..2*n+1} Fibonacci(2*k).

Let m be an even positive integer. We conjecture that the sequence defined by b_m(n) = Product_{k = 1..2*n+1} Fibonacci(m*k) / Sum_{k = 1..2*n+1} Fibonacci(m*k) is integral. The formula given below proves the conjecture in the present case m = 2. The cases m = 4 and m = 6 of the conjecture can be proved in a similar manner. More generally, if F(n,x) denotes the n-th Fibonacci polynomial we conjecture that, for each n, the rational function Product_{k = 1..2*n+1} F(m*k,x) / Sum_{k = 1..2*n+1} F(m*k,x) is an integral polynomial.

B08 A350000 - A401236 | 2,453 条

V3-015453 | OEIS-A350000

Table read by antidiagonals: T(n,k) (n >= 3, k >= 0) is the number of cells in a regular n-gon after k generations of mitosis.

Conjecture 1: For a fixed value of n, there are integers r and s, which are small compared to n, such that T(n,k) is a polynomial in k of degree r for all k >= s. Conjecture 2: Apart from the central n-gon when n is odd, any cell will eventually split into a mixture of triangles and pentagons. If we think of triangles and pentagons are harmless cells, and all other cells as dangerous, the conjecture states that (with the exception of the central odd cells), all cells eventually become harmless.

V3-015460 | OEIS-A350072

a(n) = sigma(n^2) / gcd(sigma(n^2), A003961(n^2)), where A003961 shifts the prime factorization of n one step towards larger primes, and sigma is the sum of divisors function.

Conjecture: There are no 1's after the initial term. Remark: If there were some k = x^2 > 1, for which a(x) = 1, then sigma(k) would be a divisor of A003961(k). In other words, d = A350073(k) = A064989(sigma(k)) would be a divisor of k. Then, if that divisor were also a unitary divisor [with gcd(d,k/d) = 1], it would need to satisfy the equation sigma(k) = sigma(d) * sigma(k/d) = sigma(A064989(sigma(k))) * sigma(k/A064989(sigma(k))), because sigma is a multiplicative function. (Minor correction by _Antti Karttunen_, Jul 11 2023)

Triangle T(n,k) read by rows: the number of symmetric binary n X n matrices with k ones and no all-1 2 X 2 submatrix.

T(n,5) = n*(n-1)*(n-2)*(13*n^2-n-24)/60. T(n,6) = n*(n-1)*(n-2)*(19*n^3-18*n^2-97*n+60)/180. T(n,7) = n*(n-1)*(n-2)*(n-3)*(58*n^3+75*n^2-223*n+180)/1260. - Conjectured by _R. J. Mathar_, Mar 11 2022; proved by _Max Alekseyev_, Apr 02 2022 Conjecture: the largest k such that T(n,k) is nonzero is k = A072567(n) = A001197(n) - 1. - _Max Alekseyev_, Apr 03 2022

V3-015497 | OEIS-A350742

Sisyphus with squares: a(1) = 1; thereafter, if a(n-1) is even, a(n) = a(n-1)/2; otherwise a(n) = a(n-1) + k^2, where k^2 is the smallest square (starting from 1) that has not yet been added.

This variation on A350877 was proposed by _Keith F. Lynch_ on 2022 January 28. Because the former sequence uses prime increments, and because squares grow much faster than primes, Lynch felt that my conjecture about the former sequence (that all integers eventually appear) would not be true of this sequence. I responded that because squares nevertheless grow much more slowly than exponentials, we should still expect the same basic argument, that descents to the vicinity of 1 should happen on the order of once per "era", to apply, and I still thought that all values would appear, albeit perhaps very slowly.

V3-015524 | OEIS-A351259

First noncomposite number reached when iterating the map x -> x', when starting from x = A351255(n). Here x' is the arithmetic derivative of x, A003415.

For the initial 105367 19-smooth terms of A351255, the last 7 occurs here at a(54796), with A351255(54796) = 289993286583 = 3^2 * 7 * 11 * 13^2 * 19^5, and the last 5 occurs here at a(65777), with A351255(65777) = 391899820830375516750 = 2 * 3^2 * 5^3 * 7^3 * 13^3 * 17^3 * 19^6, already a moderately high starting value, in whose vicinity most ending primes for successful iterations are much larger. This observation motivates a conjecture: Even from large numbers with high exponents in their prime factorization it is sometimes possible to reach a small prime. Compare to the conjecture 8 in Ufnarovski & Åhlander paper.

V3-015537 | OEIS-A351413

a(n) is the maximum number of stable matchings in the Latin Stable Marriage Problem of order n.

In the Latin Stable Marriage Problem of order n, the sum of a man and woman's rankings of each other is n+1. This implies that the men's and women's ranking tables are Latin squares. As a subproblem of the Stable Marriage Problem, Latin instances provide lower bounds for the maximum number of stable matchings in the general problem, such as A005154 and A065982. For sizes 1 to 4, Latin instances provide exact bounds; they are conjectured to provide exact bounds for sizes a power of 2; they provide the best lower bounds known for sizes 6, 10, 12, and 24, of 48, 1000, 6472, and 126112960, respectively. The next term, a(8), is conjectured to be 268, consistent with A005154. The

minimum number of stable matchings for Latin instances of order n is n, and is realized for the cyclic group of order n. The average number of stable matchings is 7 for n=4 (cf. A351430 showing an average of about 1.5 for the general problem), and benefits from avoidance of mutual first choices and more generally the lack of overlap between the men's and women's preferred matchings. The Latin squares of A005154 and A065982 can be interpreted as multiplication tables of groups, n-th powers of the cyclic group C2 and n-th dihedral groups, respectively.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015539 | OEIS-A351458

Numbers k for which k * gcd(sigma(k), A276086(k)) is equal to sigma(k) * gcd(k, A276086(k)), where A276086 is the primorial base exp-function, and sigma gives the sum of divisors of its argument.

A324644 gives odd values for even numbers and for the odd squares. A324198 is odd on all arguments, therefore on odd squares the above equation reduces to odd * odd = odd * odd, and on odd nonsquares as odd * even = even * odd. It is an open question whether there are any odd terms after the initial a(1)=1. It is conjectured that the intersection of this sequence with the multiperfect numbers (A007691) gives A323653, see comments in the latter.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Antti Karttunen_, Feb 13 2022 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015540 | OEIS-A351461

Lexicographically earliest infinite sequence such that a(i) = a(j) => A206787(i) = A206787(j) and A336651(i) = A336651(j) for all i, j >= 1.

Conjectured to be equal to the lexicographically earliest infinite sequence such that b(i) = b(j) => A000593(i) = A000593(j) and A336467(i) = A336467(j) for all i, j >= 1. In any case, a(i) = a(j) => b(i) = b(j) for all i, j >= 1 [because both A000593(n) and A336467(n) can be computed from the values of A206787(n) and A336651(n)], but whether the implication holds to the opposite direction is still open. Empirically this has been checked up to n = 2^22. See also comment in A351040. - _Antti Karttunen_, Nov 23 2023 The conjecture in the Nov 23 2023 comment is false. A counterexample is given by i = 21570885 = 3^2*5*7*31*47^2 and j = 39651821 = 11^3*31^3. We have A000593(i) = A000593(j) = 45067776 and A336467(i) = A336467(j) = 27, but A206787(i) = 294912 != 384 = A206787(j) and A336651(i) = 141 != 116281 = A336651(j). The first divergence occurs at n = 39651821; an exhaustive search over odd n <= 2^26 found no earlier one. Since all four functions are invariant under multiplication by powers of 2, it is enough to check odd indices. - _Clément Garrot_, Aug 25 2026

V3-015541 | OEIS-A351468

Irregular triangle read by rows where row n is Newey's sequence containing all permutations of 1..n.

For n = 3 to 7, Newey shows these sequences are as short as possible (A062714) for any sequence containing all permutations, and noted the "obvious" conjecture that maybe they would be shortest always. But this is not so, since _Jon E. Schoenfield_ gives a shorter n=16 in A062714, and Radomirovic constructs shorter for all n >= 10.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015544 | OEIS-A351496

Lexicographically earliest infinite sequence of distinct positive numbers such that, for n>2, a(n) has a common factor with the largest previous term but not with the second largest previous term.

The primes do not occur in their natural order, and the terms before and after prime values can be a large multiple of the prime, e.g. a(2147) = 3097, a(2148) = 19, a(2149) = 361. The sequence is conjectured to be a permutation of the positive integers although it may take many terms for some primes to appear, e.g., 29 has not occurred after 200000 terms. In the same range the fixed points beyond 2 are 92 and 40100, although it is possible more exist.

V3-015584 | OEIS-A352187

a(1)=1, a(2)=2; thereafter, a(n) is the smallest number m not yet in the sequence such that gcd(m,a(n-1)) > 1 and gcd(m,a(n-2))=1, except that the second condition is ignored if it would imply that no choice for m were possible.

Conjecture 1: Every positive number appears. Conjecture 2: The primes are the slowest numbers to appear. That is, when a prime p appears here, all numbers less than p have already appeared. To put this another way, the record high points in A352188 ("when does n appear") are exactly the primes (and 1). Conjecture 3: When a prime p first divides some term, that term is 2*p, which is followed by p then 3p. [It seems possible that we could see 2*a, 6*b, 3*p, p, 2*p. This does not happen in the first 10000 terms, but I can't prove it never happens. I can prove that every prime divides some term, and that the primes appear in increasing order. Conjecture 3 might be refuted by a more extensive calculation.]

V3-015614 | OEIS-A352540

Values for which the iteration of A352544 (half if even, add largest anagram if odd) does not end in a loop.

All the terms are only conjectured to have this property; we don't have a completely rigorous proof. But for all the listed initial terms, the trajectory quickly reaches numbers with many (>> 10) digits and grows larger with every iteration: When the number is odd and has a digit 0, then its successor is again odd and at least twice as large, most often more than 9 times larger. Roughly 1/10th of the digits are zeros, and similarly for 9s, so as the terms get larger, it becomes increasingly less probable that they could end up having no digit 0 at all, which is only a necessary condition that they might become even and not grow upon for one iteration, but still most likely resume growth immediately after. See sequence A352542, the trajectory of a(1) = 89, for an example studied in detail.

V3-015616 | OEIS-A352568

Take n equally spaced points on circle, connect them by a path with n-1 line segments; sequence gives number of distinct multisets of segment lengths.

Say the type of a segment is its position in the increasing list of floor(n/2) possible segment lengths. The Buratti-Horak-Rosa conjecture is that the following condition is necessary and sufficient for a multiset to be realizable as a path: for each divisor d of n, the number of segments of type divisible by d is at most n-d. The sequence confirms the conjecture up to n=37. - _Brendan McKay_, May 14 2022 If the Buratti-Horak-Rosa conjecture is true, the values of a(38)-a(50) are 144079707346575, 212327989773900, 947309492837400, 1397281501935165, 6236646703759395, 9206478467454345, 41107996877935680, 60727722660586800, 271250494550621040, 400978991944396320, 1791608261879217600, 2650087220696342700, 11844267374132633700. - _Brendan McKay_, Jun 14 2022

V3-015648 | OEIS-A352943

a(1) = 1, a(2) = 2; for n > 2, a(n) is the smallest positive number that has not appeared that shares a factor with the sum of the largest and second largest value of all previous terms.

The sequence is conjectured to be a permutation of the positive integers, although it apparently takes many terms for some primes to appear, e.g., after 200000 terms 73 has not occurred. The primes do not occur in their natural order. Beyond the first three terms there are nine fixed points in the first 200000 terms, although it is likely more exist.

V3-015651 | OEIS-A352991

Concatenation of all the distinct permutations of the first 1, 2, 3, ... (strictly) positive integers, arranged in ascending numerical order.

A001292 is a subsequence of the present sequence. An open problem, published by Kenichiro Kashihara in 1996 (see References, p. 25, #30, Problem 2), is to find how many terms of A001292 (which is a subsequence of A030299) are powers of integers; Kashihara conjectured that there are none (even if, clearly, A001292(1) = 1 should be disregarded in order to keep the conjecture alive). Currently, only the terms up to the prime a(409120) = 10123457689 have been directly checked by the author of this sequence and no nontrivial perfect power has been found. On the other hand, many (maybe infinitely many) terms of the present sequence are nontrivial powers of integers (e.g., A352329(2) to A352329(36) are squares of integers and belong to this sequence).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Marco Ripà_, Apr 16 2022 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-015678 | OEIS-A353890

a(n) is the period of the binary sequence {b(m)} defined by b(m) = 1 if (m+1)^n - m^n and (m+2)^n - 2*(m+1)^n + m^n are coprime, 0 otherwise.

For any n, consecutive n-th powers will never share a divisor > 1, so now consider the second differences. Specifically, each m > 0, define the binary sequence {b(m)} as follows: b(m) = 1 if the first difference (m+1)^n - m^n and the second difference (m+2)^n - 2*(m+1)^n + m^n are coprime, 0 otherwise. I conjecture that {b(m)} is periodic with period a(n). I conjecture that the greatest prime factor for any prime n >= 5 is phi(2^n+1)/2 + 1 = Jacobsthal(n). n*A069925 + 1 = A001045(n). I conjecture that all prime factors "f" are f=n*k+1, unless n is composite, in which case additionally all prime factors for any divisor of n will also be included in the prime factorization for a(n).

V3-015725 | OEIS-A354732

Lexicographically earliest infinite sequence of distinct positive integers such that in any run of four consecutive terms there is only one pair of terms which share a prime divisor, the rest are all pairwise coprime.

Conjecture: Sequence is a permutation of the positive integers in which the primes appear in their natural order.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _David James Sycamore_, Jun 04 2022 | 2026-10-24

V3-015726 | OEIS-A354749

a(1) = 1; for n > 1, a(n) is the smallest positive number greater than 1 that is coprime to a(n-1) and the product a(n) * a(n-1) is distinct from all previous products a(i) * a(i-1), i=2..n-1.

This is a variation of A354803 where all terms beyond the first must be greater than 1. In the first 1000000 terms the fixed points are 1,2,3,4,5,7, it is likely no more exist, while the smallest number not to have appeared is 2090. The sequence is conjectured to be a permutation of the positive integers.

V3-015763 | OEIS-A355269

Lexicographically earliest infinite sequence of distinct positive integers such that a(n+1) is prime to the number of divisors of a(n).

Conjectures: When a(n) is square a(n+1) is even; no two squares of equal parity can appear as adjacent terms; sequence is a permutation of the positive integers with primes in natural order.

V3-015765 | OEIS-A355326

Determinant of the n X n matrix [(i-j)^3+d(i,j)]_{1<=i,j<=n}, where d(i,j) is 1 or 0 according as i = j or not.

Conjecture 1: a(n) = 1 + P(n^2)*n^2*(n^2-1)/672000, where P(n) = n^6 - 19*n^5 + 123*n^4 - 337*n^3 + 12376*n^2 - 44144*n + 40000. Conjecture 2: For any positive integers m and n, the determinant of the matrix [(i-j)^m+d(i,j)]_{1<=i,j<=n} has the form 1 + n^2*(n^2-1)*P(n), where P(n) is a polynomial in n with rational number coefficients whose degree is (m+1)^2-4. The conjectures are true (see Fried link). - _Sela Fried_, Feb 01 2026

V3-015772 | OEIS-A355406

Positive integers that are not powers of 2 and whose Collatz trajectory has maximum power of 2 different from 2^4.

It is conjectured that 15/16 (93.75%) of the positive integers that are not powers of 2 have 2^4 as the maximum power of 2 in their Collatz trajectory (see A232503 and A355187). {a(n)} lists the remaining positive integers. Consequently, it is conjectured that this sequence will have lim_{n->oo} a(n)/n = 1/16.

Numerator of the permanent of the matrix [m(j,k)]_{j,k=0..2*n}, where m(j,k) is 1 or (j+k)/(j-k) according as j = k or not.

Conjecture 1. If n is a positive odd integer, x(0) = 0, and x(1),...,x(n) are variables, then the permanent of the matrix [x(j,k)]_{j,k=0..n} vanishes, where x(j,k) is 1 or (x(j)+x(k))/(x(j)-x(k)) according as j = k or not. Conjecture 2: (-1)^n*a(n) > 0 for all n = 0,1,2,... Conjecture 3: For any odd prime p, the permanent of the matrix [m(j,k)]_{j,k=0..p-1} is congruent to 1 - (-1)^((p-1)/2) modulo p, where m(j,k) is defined as in the title.. Conjecture 4: For any odd prime p, the permanent of the matrix M = [m(j,k)]_{j,k=1..p-1} is congruent to ((p-2)!!)^2 modulo p^2, and det(M) is congruent to ((p-2)!!)^2*(-1)^((p+1)/2)/(p-2) modulo p^2.

V3-015844 | OEIS-A356751

Positive integers m such that x^2 - x + m contains more than m/2 prime numbers for x = 1, 2, ..., m.

Furthermore, it is conjectured that the present sequence consists of only 16 terms (it has been checked by brute force that there are only 16 terms which are smaller than 20000) and that they are all prime or semiprime (e.g., a(12) = 161, a(13) = 221, and a(16) = 377 are semiprime). Lastly, we trivially point out that all terms must be odd, since if m is even, then x^2 - x + m is also even (and x^2 - x + 2 has only one prime for x <= 2). Stronger conjecture: for every real number e > 0 and every integer m > 0, there are finitely many integer polynomials P(x) = Ax^2 + Bx + C with at least e*m primes in P(1), ..., P(m) and max(|A|, |B|, |C|) <= m. - _Charles R Greathouse IV_, Sep 11 2022 Altering the bounds for x in the definition to 0 <= x <= m-1 (and counting the same prime twice for x=0 and x=1 if m is prime) would result in an additional term 2. Conjecturally, there would be no more additional terms. - _Pontus von Brömssen_, Jun 20 2024

V3-015849 | OEIS-A356850

a(1) = 1, a(2) = 2; for n > 2, a(n) is the smallest positive number not occurring earlier such that a(n) is coprime to the previous Omega(a(n)) terms.

The two lowest unseen numbers after 1000000 terms are 32 and 48, for former indicating that the longest run of consecutive odd values is only four after 1000000 terms. Although the sequence is conjectured to be a permutation of the positive integers, if these missing terms, especially those of the form 2^k, only appear after the recombination of the lower lines with the upper line then it may take an extraordinarily large number of terms for some values, like 2^k for large k, to eventually appear.

V3-015850 | OEIS-A356851

a(1) = 1, a(2) = 2, a(3) = 4; for n > 3, a(n) is the smallest positive number not occurring earlier such that a(n) shares a factor with the previous Omega(a(n)) terms.

For n > 250 the terms are concentrated along seven lines, see the linked images. Unlike the other six lines, numbers along the second lowest line are somewhat spread out, and these terms contain all numbers with Omega(a(n)) > 1. The lowest line contains all the primes, while the upper five lines contain terms with Omega(a(n)) = 2, 3, and 4. The primes up to n=100000 occur in their natural order except for 11 and 13 which are switched. The only fixed point beyond the first two terms is 10, and it is likely no more exist. The sequence is conjectured to be a permutation of the positive integers.

V3-015853 | OEIS-A356867

For n >= 1, write n = 3^m + k, where m >= 0 is the greatest power of 3 <= n, and k is in the range 0 <= k < 3^(m+1) - 3^m, then for n such that k=0, a(n)=n, and for n such that k > 0, a(n) is the smallest prime multiple p*a(k), p != 3, that is not already a term.

Conjectured to be a permutation of the positive integers in which the primes appear in order. The conjecture is true: Sequence is a permutation of natural numbers. By definition it is injective, and the surjectivity is guaranteed by the fact that there are infinitely many such n > k encountered by the greedy algorithm that a(n) will be a multiple of a(k), and "the smallest prime multiple" condition guarantees that all multiples of a(k) will eventually appear. That the primes and A100484 appear in order follows from the formulas a(3^m + 1) = prime(m+2), and a(3^m + 2) = 2*prime(m+2). Conjectures from _Jianing Song_, Nov 23 2022: (Start) (1) a(3^m+2) = 2*prime(m+2) for m >= 2. - [The conjecture is true because a(2) = 2 and 3^m + 2 < 3^(1+m) + (3^m) + 1 for all m - _Antti Karttunen_, Sep 16 2023] These are conjectures so far:

V3-015855 | OEIS-A356903

a(1) = 1, a(2) = 2; for n > 2, a(n) is the smallest positive number not occurring earlier such that a(n) is coprime to the previous tau(a(n)) terms.

Numbers with a large number of divisors relative to the numbers close to it appear much later in the sequence. For example a(96) = 6, a(1873) = 12, a(2328) = 18, a(192) = 16. The sequence is conjectured to be a permutation of the positive integers although it may take a very large number of terms for some values to appear, e.g., after 500000 terms numbers such as 24, 30, 36 have not occurred. In the same range the longest run of consecutive odd values is seven, while the only fixed points are the first three terms, although it is possible others exist for very large values of n if the smaller terms continue to increase relative to the uppermost line.

V3-015876 | OEIS-A357130

a(n) = 2*n - (-1)^n*(1+(n mod 2)).

Conjecture 1: Let G be an additive group with |G| > 1, and let p(G) be the minimum of those orders of nonzero elements of G (which is the positive infinity if each nonzero element of G has infinite order). Let n > 1 be an integer, and let A be a finite nonempty subset of G. Does the following extension of Conjecture 1 also hold? Conjecture 2: Let G be an additive group with |G| > 1, and let p(G) be as in Conjecture 1. Let A_1, ..., A_n (n > 1) be finite subsets of G with |A_i| > 1 for all i = 1..n. Conjectures 1 and 2 were partially confirmed by Han Wang and Zhi-Wei Sun in their preprint arXiv:2210.12044. - _Zhi-Wei Sun_, Oct 23 2022

V3-015883 | OEIS-A357271

Lower bounds for the maximum number of stable matchings in the stable marriage problem based on composing smaller instances.

a(n) is from Appendix C of Thurber's 2002 paper, using the maximum from each row. At the time of publication, the bounds were known to be exact up to n=4. A357269 shows that they are also exact for n=5. This sequence is not to be confused with A069156, also from Thurber's Appendix C, which uses only the first column, making for looser bounds for n > 11. a(6), a(8), a(10), a(12), and a(16) are also conjectured to be exact.

V3-015944 | OEIS-A357958

a(n) = 5*A005259(n) + 14*A005258(n-1).

Conjectures: There is also a product version of these conjectures: 3) the sequence {u(n): n>= 1} defined by u(n) = A005259(n)^25 * A005258(n-1)^14 conjecturally satisfies the congruences in 1) and 2) above. For the sequence u(n) = A005259(n)^25 * A005258(n-1)^14 of conjecture 3), the congruence 2) fails at p = 3: the 3-adic valuation of u(3^r) - u(3^(r-1)) equals 3*r + 2 for r = 2, 3, 4, one short of the required 3*r + 3. (The main sequence a(n) does satisfy 2) at p = 3, with valuation exactly 3*r + 3 for r = 2, 3, 4.) The data suggest that for u(n) the congruence in 2) holds modulo 3^(3*r+2) at p = 3, or equivalently that in conjecture 3) the second congruence should be restricted to primes p >= 5. - _Sunsu Jeong_, Aug 10 2026

V3-015956 | OEIS-A358094

a(n) is the number of ways n can be reached in the following method: we start with 1, then add or multiply alternately, and each operand must be 2 or 3.

Conjecture: All numbers greater than 145 can be reached in at least 3 different ways. Numbers greater than 145 which can be reached in only three ways are all of the form 27*2^k - 5 (A304387). This is conjectured to arise from the relation: 27*2^(k+2) - 5 = 3*(27*2^(k+1) - 5) - 2*(27*2^k - 5) which is in some sense here the worst case in between *2 and *3.

(End) Proof of the conjecture: We use the identities in A358095. For n > 145, if a(n) <= 2, A358095(n) <= 2. Therefore, n must be a*3*2^k - 2, where a is in the set {3, 7, 26, 30, 32, 34, 40, 49} and k is a positive integer. However, A358096(a*3*2^k - 2) = A358095(a*3*2^(k-1) - 1) >= 3, a contradiction. Hence all numbers greater than 145 can be reached in at least 3 different ways. If a(n) = 3, the only possibilities are that A358095(n) = 0 and A358096(n) = 3 or A358095(n) = 3 and A358096(n) = 0. For the first one, n must be 9*2^k - 2, so A358096(n) = A358095(9*2^(k-1) - 1) >= 4. For the second one, if n is in the form a*3*2^k - 2, A358096(n) = A358095(a*3*2^(k-1) - 1) >= 4; if n = 108*2^k - 3, A358096(n) = A358095(36*2^k - 1) >= 4; if n is in the form 108*2^k - 5, A358096(n) = 0. Hence a(n) = 3 iff n = 27*2^k - 5 for n > 145. - _Yifan Xie_, Jan 07 2025

V3-015976 | OEIS-A358339

Array read by antidiagonals upwards: A(n,k) is the number of nonequivalent positions in the KRvK endgame on an n X n chessboard with DTM (distance to mate) k, n >= 3, k >= 0.

Conjecture 1: If A(n+1,k) is nonzero, it is always greater than A(n,k). Conjecture 2: As the increments to A225552 become periodic for n>24, so too do the differences between successive polynomials over n for each k>108, and for all j, Sum_{k=2*A225552(n)-j..2*A225552(n)}(A(n,k)) is o(Sum_{k>=0}(A(n,k))) (the same equation from the opposite side). Conjecture 3: (Start) For all n, assuming conjecture 2, because the polynomials provide upper bounds and all are of degree <=5, it is necessary for the sum of all nonzero A(n,k)'s polynomials (for k<=2*A225552(n)) to have n^2 coefficients summing to 3*n^4/2. Conjecture 4: The function o (defined in the FORMULA section), for each parity of k, contains only polynomials over n (without any terms with coefficients of n%2 or (-1)**n). For all m>=3, there exists a pair of polynomials over n (for even and odd k), such that when o adds them to the output of the k-specific fitting polynomial for n=k-m, the values returned are correct for all k>=5*(m-1). (Works for m=2,3,4.) Equivalently, for all k>10, while A(n,k) can be described exactly by a k-specific polynomial over n for all n>=A052928(k), it can be described exactly by the sum of that and a (2*k-n)-specific polynomial over n (or equivalently, over k) for all n>=k-1-floor(k/5).

V3-016003 | OEIS-A359005

Jane Street's infinite sidewalk's greedy walk.

It is conjectured that the sequence actually visits all nonnegative integers. This is related to the conjecture that given any positive integer n, there exists a minimal Jane Street's path (i.e., with minimal number of jumps) going from slab 0 to slab n, and ending either in "forwards" or in "forwards-forwards-backwards". This would make the sequence a one-to-one mapping of the nonnegative numbers onto themselves. See also A359008.

V3-016006 | OEIS-A359061

Irregular table read by rows: T(n,k) is the number of k-gons formed, k>=2, among all circles that can be constructed on vertices of an n-sided regular polygon, using only a compass.

Conjecture: the only value for n which leads to the creation of 2-gons is n = 2. Despite values for n mod 6 = 0 forming intersecting arcs at the center of the n-gon, these are cut by other circles and thus create 3-gons or 4-gons. This is in contrast to values of n mod 4 = 0 in A359009 which do lead to the creation of 2-gons at the center of the figure from similar arcs.

V3-016020 | OEIS-A359349

The initial bits, written from left to right, in the 2-adic limit of the mod 2^e value of the odd factor of (2^e)!.

Here we refer to the table in the Example, in which the bits of our number, called stable bits, appear to the left of the space. Here is a conjectured relationship between the stable bits starting at any point and the unstable bits on the previous line of the table. There is a 2-adic integer K such that, for any d and n > d, uns(n,d) + K = stab(n+1,d) mod 2^d. Here uns(n,d) is the number whose backwards binary expansion (BBE) is the first d bits after the space on line n, and stab(n+1,d) is the number whose BBE is bits (n+1) to (n+d) of our number, where the numbering of the bits starts at 0. The BBE of K begins 1011011. For example, the BBE of uns(17,7) is 0101001 and that of stab(18,7) is 1110110. Perform the binary addition uns(17,7) + K from left to right on these. But computing h(m) mod 2^B can become time-consuming as m gets larger, because there are 2^(m-2) consecutive odd numbers to be multiplied. However, if the following conjecture holds, then there is a much faster way to compute those products mod 2^B, depending on the values of e and B. Conjecture: for all e,B such that 3 <= e < B <= 3*e - 5, (When d < e-1, the product on the right-hand side of the conjectured congruence requires only 1/2^(e-1-d) as many multiplications to compute, after which that product merely needs to be squared one or more times, with the residue mod 2^B taken after each squaring, so this can be much faster than taking the product on the left-hand side of the conjectured congruence.)

V3-016024 | OEIS-A359403

Primes that are the concatenation of the first m consecutive k-th powers.

Let cp(k, n) denote the concatenation of the first n k-th powers. Note that there are no primes in cp(1, n) = A007908(n) up to n = 64000 or cp(3, n) = A019522(n) up to n = 31152. But there is a prime in cp(2, n) = A019521(n): cp(2, 3) = A019521(3) = 149. Conjecture: if k is odd, no "smaller primes" (< 10000 digits, or non-gigantic primes) exist in cp(k, n); if k is even, then such primes may occur. So far, the expanded search supports this conjecture. For k

from 5 to 500, when k is an odd number, we have found no "smaller primes" in cp(k, n); for even k, the following primes have been found: However, the next search contradicted the above conjecture. For k from 501 to 1100, we get two counterexamples:

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Michel Marcus_, Dec 30 2022 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016025 | OEIS-A359416

Write n as 2^m - k, where 2^m is the least power of 2 >= n (0 <= k <= 2^(m-1)-1). For n a power of 2 (k = 0), a(n) = n. For numbers with k > 0, a(n) is the least p*a(k) which has not occurred previously, the count of k being taken from right to left (backwards) from k = 1 at 2^m - 1.

Conjectured to be a permutation of the positive integers in which primes appear in natural order. The even bisection, when divided by 2, reproduces the sequence.

Number of vertices in a Farey fan of order n.

The number of vertices along each edge is A005728(n), while the number of regions is conjectured to equal A005598(n) = 1 + Sum_{i=1..n} (n-i+1)*phi(i). The regions count the number of distinct approximate representations of straight lines y = mx + b that can be drawn on an x-y integer raster, where x, y, and b are restricted to [0,n) and 0 <= m <=1.

V3-016069 | OEIS-A360278

Determinant of the matrix [L(j+k) + d(j,k)]_{1<=j, k<=n}, where L(n) denotes the Lucas number A000032(n), and d(j,k) is 1 or 0 according as j = k or not.

Conjecture 1: Let v(0) = 2, v(1) = A, and v(n+1) = A*v(n) + v(n-1) for n > 0. Then A^2*det[v(j+k) + d(j,k)]_{1<=j, k<=n} = v(n+1)^2 - (A^2 + 4)*(n mod 2) for any positive integer n. In particular, a(n) = L(n+1)^2 - 5*(n mod 2) for all n > 0. Conjecture 2: Let v(0) = 2, v(1) = A, and v(n+1) = A*v(n) - v(n-1) for n > 0. Then det[v(j+k) + d(j,k)]_{1<=j, k<=n} = u(n+1)^2 - n^2 for any positive integer n, where u(0) = 0, u(1) = 1, and u(n+1) = A*u(n) - u(n-1) for all n > 0. Conjecture 3: Let F(n) denote the Fibonacci number A000045(n). Then, for any positive integer n, we have det[F(j+k) + d(j,k)]_{1<=j, k<=n} = F(n+1)^2 + (n mod 2).

V3-016070 | OEIS-A360374

Indices of the nonprimitive rows of the Wythoff array (A035513); see Comments.

In a row of the Wythoff array, either every two consecutive terms are relatively prime or else no two consecutive terms are relatively prime. In the first case, we call the row primitive, as in A332938. Otherwise, the row is an integer multiple of a tail of a preceding row, and we call the row nonprimitive. Conjecture: the limiting proportion of nonprimitive rows exists and is approximately 0.392.

V3-016097 | OEIS-A361036

a(n) = n! * [x^n] (1 + x)^n * exp(x*(1 + x)^n).

We conjecture that a(n+k) == a(n) (mod k) for all n and k. If true, then for each k, the sequence a(n) taken modulo k is a periodic sequence and the period divides k. For example, modulo 7 the sequence becomes [1, 2, 4, 5, 6, 0, 4, 1, 2, 4, 5, 6, 0, 4, 1, 2, 4, 5, 6, 0, 4, ...], apparently a periodic sequence of period 7. More generally, let F(x) and G(x) denote power series with integer coefficients with F(0) = G(0) = 1. Define b(n) = n! * [x^n] exp(x*G(x)^n)*F(x)^n. Then we conjecture that b(n+k) == b(n) (mod k) for all n and k. The conjectures above are true, see Turazashvili links. - _Nikoloz Turazashvili_, Aug 22 2026

V3-016102 | OEIS-A361127

Let p = n-th odd prime; a(n) = index where 2*p appears in A360519, or -1 if 2*p never appears.

It is conjectured that every 2*prime(n) (n>1) appears in A360519. A proof of this would be a big step towards proving that every term of C appears in A360519.

V3-016107 | OEIS-A361281

a(n) = n! * Sum_{k=0..n} binomial(n*k,n-k)/k!.

It appears that a(n) == 1 (mod 4) and a(5*n+2) == 0 (mod 5) for all n. More generally we conjecture that a(n+k) == a(n) (mod k) for all n and k. If true, then for each k, the sequence a(n) taken modulo k is a periodic sequence and the period divides k. Let F(x) and G(x) be power series with integer coefficients with G(0) = 1. Define b(n) = n! * [x^n] F(x)*exp(x*G(x)^n). Then we conjecture that b(n+k) == b(n) (mod k) for all n and k. The present sequence is the case F(x) = 1, G(x) = 1 + x. Cf. A278070. (End)

V3-016140 | OEIS-A361888

a(n) = S(5,n)/S(1,n), where S(r,n) = Sum_{k = 0..floor(n/2)} (binomial(n,k) - binomial(n,k-1))^r.

For r a positive integer define S(r,n) = Sum_{k = 0..floor(n/2)} (binomial(n,k) - binomial(n,k-1))^r. Gould (1974) conjectured that S(3,n) was always divisible by S(1,n). See A183069 for {S(3,n)/S(1,n)}. In fact, calculation suggests that if r is odd then S(r,n) is always divisible by S(1,n). The present sequence is {S(5,n)/S(1,n)}.

V3-016145 | OEIS-A361919

The number of primes > A000040(n) and <= (A000040(n)^c + 1)^(1/c), where c = 0.567148130202... is defined in A038458.

Let c = 0.567148130202... (see A038458), the solution to 127^x - 113^x = 1. c is conjectured by Smarandache to be the smallest real number x such that A000040(n+1)^x - A000040(n)^x = 1 has a solution. This conjecture is equivalent to saying that the terms of the present sequence are always positive, but that if c were replaced by a larger real number, there would be zeros in the sequence. However, note that a(30) is not the last occurrence of 1: a(46) = a(61) = 1 as well.

V3-016182 | OEIS-A362631

Lexicographically earliest infinite sequence of distinct positive integers with a(n) = n for n <= 3, and for n > 3 a(n) is the least novel multiple of the greatest prime divisor of a(n-2) which does not divide a(n-1).

Conjectured to be a permutation of the positive integers with the primes in order.

V3-016199 | OEIS-A362866

Numbers k with the property that the parts of the symmetric representation of sigma(k) are two octagons.

Conjecture 1: The octagons are S-shaped and they have width 1. Conjecture 2: This sequence is also the primes doubled (or even semiprimes) >= 10 (Cf. A100484). - _Omar E. Pol_, Aug 15 2023 For the symmetric representation of sigma(n) to consist of 2 octagons the first 3 entries in row n of the triangle of A249223 must be nonzero, hence must be 1's, indicating width 1, with the remaining entries zero. Therefore, row n of A237048 is 100100..., implying n = 2*p with p>3 prime. Both conjectures are true. - _Hartmut F. W. Hoft_, Aug 22 2023

V3-016219 | OEIS-A363308

Expansion of g.f. C(x*C(x)^3), where C(x) = 1 + x*C(x)^2 is the g.f. of the Catalan numbers (A000108).

Conjecture: a(n) is odd iff n is a power of 2 or n = 0.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Paul D. Hanna_, May 28 2023 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016220 | OEIS-A363309

Expansion of g.f. A(x) = F(x*F(x)^5), where F(x) = 1 + x*F(x)^3 is the g.f. of A001764.

Conjecture: given A(x) = F(x*F(x)^(2*n-1)) where F(x) = 1 + x*F(x)^n, let B(x) = A(x*B(x)^(n-1)), then ((B(x) - 1)/x)^(1/(2*n-1)) is an integer series for n >= 1. Incidentally, the function A(x) = F(x*F(x)^(2*n-1)) is interesting because F(-x*F(x)^(2*n-1)) = 1/F(x) when F(x) = 1 + x*F(x)^n. This sequence illustrates the case for n = 3; for n = 2, see A363308.

V3-016221 | OEIS-A363321

Number of fractions of the Farey sequence of order n, F_n, that coincide with those of the sequence of the #{F_n} equally distributed fractions between 0 and 1.

The conjectured formula below suggests that as the value of n increases, the proportion of terms in the Farey sequence F_n that align with the #F_n rationals, evenly distributed between 0 and 1, tends to decrease. Conjecture: lim_{n->infinity} a(n)/A005728(n) = 0.

V3-016222 | OEIS-A363364

Least nonnegative integer k such that all non-bipartite graphs with n nodes and at least k edges are weakly pancyclic.

Brandt (1997) conjectures that a(n) = floor((n-1)*(n-3)/4) + 5 for n >= 6. The conjecture is false for n = 8, since there exists a (unique) non-bipartite, not weakly pancyclic graph (shown below) with 8 nodes and 13 edges, showing that a(8) >= 14. This graph contains cycles of lengths 3, 4, 5, 6, and 8, but none of length 7.

V3-016224 | OEIS-A363381

a(n) is the number of distinct n-cell patterns (or quasi-polyominoes) that tile an n X n square.

Conjecture by Andrew Young: For an n X n square, where n is an odd prime, there is only one n-cell pattern. Conjecture by Andrew Young and Thomas Young: An odd integer n>=3 is prime iff there exists only one n-cell pattern for an n X n square. The second conjecture is a Corollary of the first: If n = p*q is not prime, then there is always a second tiling using rectangles, as explained above. Since the second conjecture implies the first, the two conjectures are actually equivalent. - _M. F. Hasler_, Jun 15 2025 For n > 1, a(n) = 1 iff n is an odd prime (conjectured: cf comments).

V3-016256 | OEIS-A363985

a(n) = Sum_{k = 0..n} (-4)^(n-k)*binomial(n,k)*binomial(2*n+k,k)*binomial(2*k,k).

The Franel numbers satisfy the supercongruences u(n*p^r) == u(n*p^(r-1)) (mod p^(3*r)) for all primes p >= 5 and positive integers n and r. We conjecture that the present sequence satisfies the same supercongruences. More generally, define two families of sequences {u_m(n): n >= 0} and {v_m(n): n >= 0}, depending on an integer parameter m, by u_m(n) = Sum_{k = 0..n} (-4)^(n-k)*binomial(n,k)*binomial(m*n + k,k)*binomial(2*k,k) and v_m(n) = Sum_{k = 0..n} (-4)^(n-k)*binomial(n,k)*binomial(m*n + 2*k,2*k)*binomial(2*k,k). In this notation, the Franel numbers A000172 = v_1. Note that u_0(n) = v_0(n) = (-1)^n*binomial(2*n,n). We conjecture that, for all m in Z, the sequences u_m and v_m satisfy the above supercongruences.

V3-016288 | OEIS-A364366

An irregular triangle read by rows, the 3rd row-symmetric Fibonaccian triangle: T(n,k) is the Whitney number of level k of the (3,n)-th symmetric Fibonaccian lattice (0 <= n, 0 <= k <= 2*n).

In [Donnelly, Dunkum, Lišková, and Nance, 2023], the (m,n)-th symmetric Fibonaccian lattice L is also described using semistandard tableaux of a specific ribbon shape; the irreducible components of the associated sl(m,C)-representation are in one-to-one correspondence with what are called the 'ballot-admissible' (aka Littlewood-Richardson) tableaux. In terms of Fibonaccian strings, an element S = (S(1),...,S(n)) in L is ballot-admissible iff for any integer q between 1 and n (inclusive) and any integer r between 1 and m-1 (inclusive), the following integer quantity is nonnegative: Sum_{k=n+1-q..n}([n+1-k is odd]*([r+(k-1)*m = S(k)] - [r+(k-1)*m+1 = S(k)]) + [n+1-k is even]*([k*m-r = S(k)]-[k*m+1-r = S(k)])), where '[]' denotes the Iverson bracket. Enumerating the ballot-admissible tableaux or Fibonaccian strings in L seems to be an interesting problem when m >= 3; when m=3, the sizes of the sets of ballot-admissible tableaux conjecturally agree with A004148.

V3-016289 | OEIS-A364414

Numbers k with the property that the second part of the symmetric representation of sigma(k) is an octagon of width 1 and one of its vertices is also the central vertex of the first valley of the largest Dyck path of the diagram.

Conjecture 1: These are the numbers > 9 that are congruent to {3, 9, 21, 27} mod 30. Conjecture 2: These are the terms > 9 of A016945 except the terms ending in 5. Conjecture 3: The polygon mentioned in the definition is an "S"-shaped concave octagon. Conjecture 4: Every term of this sequence has as nearest neighbor a term of A091999. Conjecture 5: The terms of A091999 greater than 2 are the numbers k with the property that the first part of the symmetric representation of sigma(k) is an octagon. Conjecture 6: The octagon mentioned in the definition shares at least an edge with the octagon mentioned in conjecture 5.

V3-016290 | OEIS-A364421

For n >= 3, r >= 0, y an integer, a(n) is the number of integral solutions to the elliptic equation y^2 = n^3 + n^2 + 2*r*n + r^2.

Factoring the equation y^2 = n^3 + n^2 + 2*r*n + r^2 yields (y+n+r)*(y-n-r) = n^3, which implies y+n+r = d and y-n-r = n^3/d for some divisor d of n^3. Thus a(n) is the number of divisors d of n^3 such that (d-n^3/d)/2 - n is a nonnegative integer. This resolves some of Thomas Scheuerle's conjectures. - _Robin Visser_, Sep 30 2023 Conjecture: a(A190300(n)) = 3. Conjecture: a(A196226(n)) = 4. Conjecture: a(p^3) = 5 if p is an odd prime. Conjecture: a(2*p^2) = 7 if p is an odd prime. But there exist other cases too, for example a(3*23) = 7. Conjecture: a(prime(n)^prime(n)) = A245685(n - 1) - 1. (End)

V3-016331 | OEIS-A365028

a(n) = Sum_{k = 0..n} (-1)^(n+k) * binomial(n,k)*binomial(n+k-1,n)* binomial(3*n+k-1,n).

The central binomial coefficients A000984(n) satisfy the supercongruences A000984(n*p^r) == A000984(n*p^(r-1)) (mod p^(3*r)) for all primes p >= 5 and all positive integers n and r (see Meštrović, equation 39). We conjecture that the present sequence satisfies the same supercongruences. More generally, for M a positive integer and integers A, B and C, we conjecture that the sequence whose n-th term is given by Sum_{k = 0..M*n} (-1)^(n+k) * binomial(A*n,k)*binomial(B*n+k-1,n)*binomial(C*n+k-1,n) also satisfies the same supercongruences.

V3-016364 | OEIS-A365625

a(0) = 0, a(1) = 1. let i = a(n-2) and j = a(n-1), then if i,j have a digit in common a(n) is the least novel number having no digit in common with either i or j. If i,j have no common digit, a(n) is the least novel number having a digit in common with at least one of i or j. All digits are decimal.

The sequence is conjectured to be finite. It will end if for some m, a(m) is a pandigital number, or if the set {i,j} of distinct digits of i and j contains all nonzero digits, whichever happens first. In the latter case the definition would require the next term to consist entirely of 0's, but since 0 is already a term this is impossible. A sequence like this can be made using any base.

V3-016408 | OEIS-A366952

a(1) = 1, a(2) = 4; for n > 2, a(n) is the smallest positive number that has not yet appeared that shares a factor with n but does not equal n, and shares a factor with a(n-1).

The sequence is conjectured to be a permutation of the positive integers, although the primes typically take many terms to appear, e.g., a(95890) = 223. When a prime does appear it is often followed by a term that is significantly larger than the average-sized term. See the examples below. The primes do not occur in their natural order.

V3-016413 | OEIS-A367082

a(1), a(2) = 2. Thereafter a(n) is the least novel multiple of the greatest prime which divides precisely one of a(n-1), a(n-2) but not the other. If no such prime exists a(n) is the least novel multiple of the smallest prime dividing neither a(n-1) nor a(n-2).

Conjecture: This is a permutation of the positive integers, with primes in order. Each prime p generates a trajectory T(p), dominated by multiples of p, see graph. Typically T(prime(k)) is initiated following the earliest term divisible by prime(k). Some trajectories are more prominent in the graph than others e.g. T(7),T(11),T(13) extend from p = prime(k) to prime(k+1)*prime(k). Others, e.g. T(3) terminate earlier but include prime(k)^2, whilst some do not reach as far as prime(k)^2 (T(5) has just two terms). Thus three categories of prime trajectory can be distinguished in the graph (respectively "full", "medium" and "small"). The graph resembles an inclined comb whose teeth correspond to full and medium trajectories; see Example.

V3-016419 | OEIS-A367147

Index of matching grid point in the bijection between two infinite triangular grids with one grid rotated by Pi/6 around the common point (0,0), using an enumeration of the grid points by A307014 and A307016.

While the method described only finds a minimum of the maximum distance of approximately 0.9659 by assigning the bijection partners using tiles, applying the Hopcroft-Karp algorithm to the bipartite graph corresponding to a sufficiently large section of the two infinite grids achieves significantly lower maximum distances. We conjecture that an upper bound for the maximum distance is sqrt(2)/2~=0.7071. See the corresponding link. A method that reduces the maximal occurring bijection distance to its conjectured minimum, and only requires local rearrangements, as described for the square grids in A307731, is currently not known in the present case of the triangular grids.

V3-016432 | OEIS-A367396

Number of subsets of {1..n} whose cardinality is the sum of two distinct elements.

Conjectures from _Chai Wah Wu_, Nov 21 2023: (Start)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Gus Wiseman_, Nov 21 2023 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016433 | OEIS-A367400

Number of subsets of {1..n} whose cardinality is not the sum of two distinct elements.

Conjectures from _Chai Wah Wu_, Nov 21 2023: (Start) The two conjectures of Chai Wah Wu above are true. Proof: write g(f,p,k) = [x^k] (1+2*x)^p*(1+x)^f and T_s(n) = Sum_{p=0..floor(n/2)} g(n-2*p, p, 2*p+s), so that a(n) = 1 + T_1(n) + T_2(n) by the formula above. Pascal's rule in f gives T_{s+1}(n+1) = T_{s+1}(n) + T_s(n), and in p it gives T_s(n+2) = binomial(n+2,s) + T_{s+2}(n) + 2*T_{s+1}(n). The first identity for s = 1, 2 and the second for s = 1 form a linear system from which the recurrence follows, and the initial terms 1, 2, 4, 7 then give the g.f. Both the formula and the recurrence are formalized in Lean 4 (see Links).

V3-016439 | OEIS-A367504

a(1) = 2; for n > 1, a(n) = a(n-1) + 2*gpf(a(n-1)), where gpf(k) = A006530(k) = greatest prime dividing k.

Conjecture: with the requirement that the prime factorization of each term is written so that the primes are ordered from smallest to largest, the sequence is the lexicographically earliest infinite sequence of distinct positive numbers such that gpf(a(n-1)) * lpf(a(n)) = |a(n) - a(n-1)|, where gpf(k) = A006530(k) = greatest prime factor of k and lpf(k) = A020639(k) = least prime factor of k. In this way the sequence is the ordered prime factorization version of the 'Commas sequence', A121805. One can show that, for such a sequence to be infinite, no odd number can appear. Although for many terms a lower even number can be chosen for the following term, which can lead to even lower numbers for further terms, it is conjectured all such choices will ultimately halt the sequence as a number is eventually reached for which no unused next number exists which follows the required rule for the difference between the terms. Therefore all terms must be larger than the previous, and the earliest such infinite sequence is the given sequence.

V3-016486 | OEIS-A369110

a(n) is the number of distinct elements appearing in the sequence formed by recursively applying A063655 when starting from n.

A063655(n) gives the smallest semiperimeter of an integral rectangle with area n, which is the same thing as the minimum sum of two positive integers whose product is n. In this sequence, A063655 is applied recursively until a cycle is found. Then the number of distinct elements appearing in this process is given as a(n). Note that it's conjectured that a cycle will be found at some point. Conjecture: The cycle part of each sequence generated by the recursion is one of (4), (5, 6), or (6, 5). Confirmed through 1 millionth term. The conjecture is true. Proof: The conjecture holds for n <= 6. Suppose n >= 7 and the conjecture holds for lower values of n. If n is composite, then A063655(n) <= n/2+2. If n is prime, then A063655(n) = n+1 is even and A063655(A063655(n)) <= (n+1)/2+2. In both cases, n reaches a lower number and the conjecture holds for n. - _Jason Yuen_, Mar 30 2024

V3-016495 | OEIS-A369375

Numbers m such that the Mersenne number 2^m - 1 is a de Polignac number (A006285).

Cf. A138290 (see _Chai Wah Wu_'s conjecture in the third comment). By Crocker's (1971) theorem: if m > 2 and a <> b, then 2^(2^m)-1 - 2^a - 2^b is not prime. Conjecture: if n > 5, then |2^(2^n-1)-1 - 2^m| is not prime for every m > 0. If so, then by the dual Riesel conjecture, 2^(2^n-1)-1 is a (dual) Riesel number, i.e., if n > 5, then (2^(2^n-1)-1)2^m-1 is composite for every integer m > 0.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Thomas Ordowski_, Jan 22 2024 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016496 | OEIS-A369378

a(n) is the smallest k such that 2^(2^n+1)-1 + 2^k is prime, or -1 if no such k exists.

Conjecture: if n > 0, then 2^(2^n+1)-1 + 2^k is not prime for every k < 2^n. This conjecture seems provable, because it is not too strong for large n > 6. If, for n > 6, a(n) does not exist, then 2^(2^n+1)-1 + 2^k is composite for every natural k. Thus, by the dual Sierpinski conjecture, for n > 6, 2^(2^n+1)-1 is a Sierpinski number, i.e., if n > 6, then (2^(2^n+1)-1)2^k+1 is composite for every natural k. For example, the Mersenne number 2^(2^8+1)-1 may be a dual Sierpinski number. Similarly, if for n > 5, |2^(2^n-1)-1 - 2^m| is not prime for every m > 0, then by the dual Riesel conjecture, 2^(2^n-1)-1 is a Riesel number, i.e., if n > 5, then (2^(2^n-1)-1)2^m-1 is composite for every integer m > 0. For example, the double Mersenne prime 2^(2^7-1)-1 may be a dual Riesel number. By Crocker's theorem; if n > 2, then positive 2^(2^n-1)-1 - 2^m are composite. Let b(n) be the smallest k such that 2^k - (2^(2^n-1)-1) is prime, for n >= 0: {1, 2, 39, 47, 447, 191, ?}.

V3-016502 | OEIS-A369653

a(n) = 1 if A327860(n) is a multiple of 3, otherwise 0, where A327860 is the arithmetic derivative of the primorial base exp-function.

Conjecture: asymptotic mean is 4/9: One third of the primorial base representations (A049345 from which the intermediate value x = A276086(n) is built from) have "2" as their second rightmost digit (out of 0, 1, 2). That 2 is converted by A276086 to 3^2, so as x is a multiple of nine, it is guaranteed that x' [= A003415(x)] gives a multiple of three. If the second rightmost digit is "1", then x = A276086(n) is a multiple of 3 (but not of 9), and its arithmetic derivative, x' = 3*(x/3)' + (x/3), certainly is not a multiple of 3. This leaves the case where the second rightmost digit is "0", and conjecturing now in this case that the modulo 3 remainders are eventually evenly distributed for x' (see A359430 and A373256), at least among the number of the form A048103, it gives in this case 1/3 * 1/3 = 1/9 probability that x' is a multiple of 3, so the total probability would be 1/3 + 0 + 1/9 = 4/9. Note that Sum_{i=1..10^n} a(i), for n = 1..8 gives: 3, 43, 443, 4443, 44443, 444443, 4444444, 44444444, so empirically the value 4/9 seems very sharp. - revised Jun 18 2024.

V3-016505 | OEIS-A369686

LCM-transform of A359804 (see Comment and links).

The property S (as defined in A368900) refers to what is observed in the positive integers (A000027), and also in the Doudna sequence (A005940), whereby each prime power appears prior to any of its multiples. The present sequence does not have this property since, for example, 26 = a(31) precedes 13 = a(42). Thus A369804 represents a significant disturbance of A000027 in that whereas it is conjectured to be a permutation of the positive integers, it does not preserve one of the basic properties of that sequence.

a(1,2) = 1,2; thereafter let i = a(n-2) and r(n) = a(1)*a(2)*...*a(n-1): a(n) is the smallest novel multiple m of w = rad(r(n))/rad(i), where rad is A007947.

(i). Directly: rad(i) = rad(r(n)) implies a(n) is the least unused term, conjectured to be the smallest prime p not already in the sequence. In this case no prior term is divisible by p. This happens for 3, 5, 7. It is not known if this ever happens again (thought to be unlikely).

V3-016519 | OEIS-A369988

Decimal expansion of Mallows's constant or stribolic constant kappa (of order 1).

In 1997, Colin Mallows observed and conjectured that the rows in Levine's triangle A012257 take on stribolic shape and that A011784(n+1)/(A011784(n)*A011784(n-1)) converges as n->oo. Presuming his conjecture, the limit would equal kappa, while Mallows estimated it to be "approximately ... 0.277", see A011784. Later, in 2006, Martin Fuller suggested 0.27887706... for the limit, based on a numerical iteration, see A012257. Set kappa_n := A369990(n) / A369991(n) and theta_n := (kappa_n-kappa_{n+1}) / (kappa_{n-1}-kappa_n). Under the hypothesis that theta_{2m} < theta_{2m+2} < theta_{2*m+3} < theta_{2*m+1} for m=1,2,... (verified for all values known so far), we would obtain 0.27887706136895087 < kappa_{21}' < kappa < kappa_{22}' < 0.27887706136898083, which is sharper than formula (3) below. Here, the transformed sequence (kappa_n') = G(kappa_n) is defined via kappa_n' := (kappa_{n-1}*kappa_{n+1} - kappa_n^2) / (kappa_{n-1} - 2*kappa_n + kappa_{n+1}). (See first arXiv article for a proof of this conjecture-dependent statement.) Feeling even more adventurous, we could apply the transformation G four times and would obtain 0.278877061368975064775 < kappa_{19}'''' < kappa < kappa_{18}'''' < 0.278877061368975064815. It is an open question whether kappa is rational or irrational, algebraic or transcendental.

V3-016527 | OEIS-A370164

The number of residues mod n that occur among the Markov numbers.

It is conjectured that, modulo n, all residues not forbidden by the constraints in the three comments above are actually realized by some Markov number. Specifically, mod n the forbidden residues include the following: (1) if p is a prime congruent to 3 (mod 4) that divides n, then any residue congruent to 0 (mod p) or congruent to either of the forbidden residues listed in the second comment (mod p), (2) if 4 divides n, then any odd residue congruent to 3 (mod 4), (3) if 2^r is the highest power of 2 dividing n and 2 <= r <= 5, then any even residue not congruent to 2 (mod 2^r), (4) if 2^r is the highest power of 2 dividing n and r > 5, then any even residue not congruent to 2 (mod 32). It is conjectured that all other residues occur. This has been verified for all n <= 38000. If the conjecture in the previous comment is correct, then it follows from the Chinese remainder theorem that a(n) may be found by writing n = 2^s * 3^t * u * p_1^r_1 * p_2^r_2 * ... * p_k^r_k, where p_1, ..., p_k are distinct primes greater than 3 and congruent to 3 (mod 4) and r_1, ..., r_k are positive and where the prime divisors of u are all congruent to 1 (mod 4). Then a(n) = u * C_s * D_t * Product_{j=1..k} (p_j - 3) * p_j^(r_j - 1), where C_s = 2^s if s < 2, 1 + 2^(s-2) if 2 <= s <= 5, and 2^(s - 5) + 2^(s - 2) if s > 5, and where D_t = 1 if t = 0 and 2 * 3^(t-1) if t > 0. If the conjecture holds then a(n) is a multiplicative function. Conjectured: write n = 2^s * 3^t * u * p_1^r_1 * p_2^r_2 * ... * p_k^r_k, where p_1, ..., p_k are distinct primes greater than 3 and congruent to 3 (mod 4) and r_1, ..., r_k are positive and where the prime divisors of u are all congruent to 1 (mod 4). Then a(n) = u * C_s * D_t * Product_{j=1..k} (p_j - 3) * p_j^(r_j - 1), where C_s = 2^s if s < 2, 1 + 2^(s-2) if 2 <= s <= 5, and 2^(s - 5) + 2^(s - 2) if s > 5, and where D_t = 1 if t = 0 and 2 * 3^(t-1) if t > 0.

a(1) = 1; for n > 1, a(n) is the smallest unused positive number such that sopfr(|a(n) - a(n-1)|) = sopfr(a(n) + a(n-1)) and Omega(|a(n) - a(n-1)|) = Omega(a(n) + a(n-1)), where sopfr(k) is the sum of the primes dividing k, with repetition.

The fixed points begin 1, 306, 13442, 24566, 30607, 53557, 65136; it is likely there are infinitely more. The sequence is conjectured to be a permutation of the positive integers, although it takes many terms for some values to appear, e.g., a(177950) = 9.

V3-016547 | OEIS-A370526

Square array read by descending antidiagonals: Define function b(i,n,k) where b(0,n,k) = n, b(1,n,k) = k, b(i,n,k) = A038502(b(i-1,n,k) + b(i-2,n,k)). T(n,k) is the number of steps until reaching the cyclic part of {b(i,n,k)}, or -1 if no cycle exists.

Conjecture: T(n,k) >= 0. This conjecture can be supported by a heuristic argument: Using dynamic programming, we can compute that for p's in A000057, the probability that b(i-1,n,k) + b(i-2,n,k) is not divisible by p is (p-2)/p, and the probability that valuation(b(i-1,n,k) + b(i-2,n,k), p) = x (x >= 1) is 2*(p-1)/p^(x+1). Therefore, the mathematical expectation of a(i) is (a(i-1,n,k) + a(i-2,n,k))*(p-1)/(p+1), which is exactly the average of the earlier two terms when p = 3, and larger when p >= 5.

V3-016551 | OEIS-A370662

Numbers m such that 3 does not divide the m-th Catalan number A000108(m); m such that A067397(m) = 0.

Conjecture: the only terms of the form 2^r-1 are 0, 1, 3, 31 and 255. Since 2^r-1 !== 2 (mod 3), this is equivalent to saying that the only numbers of the form 2^r-1 that have no digits 2 in ternary are 0, 1, 3, 31, 255. The conjecture would imply that the n-th Catalan number is divisible by 2 or 3 other than n taking these values.

V3-016586 | OEIS-A372060

a(n) = smallest k such that A252867(k) = n, or -1 if no such k exists.

Both A252867 and this sequence are conjectured to be permutations of the nonnegative integers, in which case they are inverses of each other.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _N. J. A. Sloane_, May 01 2024 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016587 | OEIS-A372063

a(n) = A280864(n) - A280866(n).

A280864 and A280866 are closely related. There is a proof that A280866 is a permutation of the positive integers, but for A280864 this is only a conjecture. The present sequence compares them term-by-term; A372064 compares their inverses; and A372065 compares where the primes appear.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016600 | OEIS-A372368

a(1) = 1. Thereafter, if A007947(a(n-1)) is a term in A002110, a(n) is the smallest prime not already in the sequence. Otherwise a(n) is the smallest novel multiple of p, the greatest prime < g = gpf(a(n-1)).

A term whose radical is in A002110 occurs only if the multiplier m (of prime q) is in A002110, either with q|m, or with q the smallest prime > gpf(m). Thus all multiples of every prime will appear and it is therefore conjectured that this sequence is a permutation of the positive integers, A000027.

V3-016601 | OEIS-A372385

Determinant of the matrix [Jacobi(i - j, 2n + 1)]_{0 < i, j < n}, where Jacobi(a, m) denotes the Jacobi symbol (a/m).

In a 2003 preprint, R. Chapman conjectured that if 2*n + 1 (with n > 1) is a prime congruent to 3 modulo 4, then a(n) = 1. Conjecture 1: If p = 2*n + 1 is a prime congruent to 1 modulo 4, then det[x + Jacobi(i - j, p)]_{0 < i, j < n} = r_p - 2*s_p + (-1)^{n/2}*x*(2*r_p - p*s_p), and det[x + Jacobi(i - j, p)]_{0 <= i, j <= n} = -r_p + (-1)^{n/2}*p*s_p*x, where r_p and s_p are rational numbers such that e_p^{(2 - Jacobi(2, p))*h(p)} = r_p + s_p*sqrt(p), e_p and h(p) are the fundamental unit and the class number of the real quadratic field Q(sqrt(p)), respectively. Conjecture 2: Suppose that p = 2*n + 1 is a prime greater than 3, and write e_p^{h(p)} = a_p + b_p*sqrt(p) with 2*a_p and 2*b_p integral. We have checked both conjectures for n up to 1000.

V3-016602 | OEIS-A372409

Determinant of the matrix obtained from [Jacobi(i-j, 2*n+1)]_{0<i,j<n} by replacing all the entries in the first row by 1, where Jacobi(a,m) denotes the Jacobi symbol (a/m).

Conjecture 1: If 2*n + 1 (with n > 1) is a prime p, then a(n)/floor((p-2)/3) coincides with (-1)^((p+3)/4) if p == 1 (mod 4), and (-1)^((h(-p)+1)/2) if p == 3 (mod 4), where h(-p) is the class number of the imaginary quadratic field Q(sqrt(-p)). Conjecture 2: Let p > 3 be a prime, and let S(p) and T(p) denote the matrices obtained from [Jacobi(i+j,p)]_{1<=i,j<=(p-3)/2} and [Jacobi(i+j,p)]_{0<=i,j<=(p-3)/2} (respectively) by replacing all the entries in the first row by 1. Then det S(p) = -det T(p) = 2^((p-5)/2)*s(p), where s(p) is (-1)^((p+3)/4) if p == 1 (mod 4), and (-1)^((h(-p)-1)/2) if p == 3 (mod 4). Both conjectures are motivated by Conjecture 4.6 in the author's 2019 FFA paper as well as the conjectures in A372385. They have been verified for primes p < 2000.

V3-016657 | OEIS-A373516

Number of sets that can be represented as a length-n combination of commas and braces, with elements possibly repeated.

It is conjectured that there are only finitely many n such that a(n) > a(n+1), with n=11 being the last example.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Bryle Morga_, Jun 08 2024 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016658 | OEIS-A373545

a(1) = 1, a(2) = 2; for n > 2, a(n) is the smallest unused positive number that shares a factor with a(n-1) if a(n-1) is odd otherwise is coprime to a(n-1) if a(n-1) is even.

The terms studied are all concentrated along lines of different gradient; the odd terms all being on the line a(n) = n or very close to it, while the even terms are distributed among the other lines dependent on the number of prime factors they contain. It is conjectured that this behavior is true for all n. The topmost line contains even semiprimes while the lower lines, those with gradient less than 1, contain powers of 2 multiplied by a larger single prime. However the topmost of these lower lines, which is more diffuse, also contains all other even numbers. Also noticeable is some of the lower lines terminating after which these values appear to move into the line contains all other even numbers. Conjecture: Odd prime p precedes 2*p. Conjecture: Odd prime p appears for odd n, but additionally, tends to occupy a(n) such that n mod A002110(k) is a reduced residue of the largest A002110(k) < n. Thus, a(n) = p for n <= p. Example, a(65) = 67 is displaced. However, generally primes represent fixed points. (End)

V3-016667 | OEIS-A373623

a(n) = n for n <= 3; for n > 3, a(n) is the smallest unused positive number that shares a factor with the most recently appearing even number if a(n-1) is odd, otherwise it shares a factor with the most recently appearing odd number if a(n-1) is even.

The terms studied are all concentrated along lines of different gradient; the prime numbers are all distributed on the lines with gradient < 1 while all other numbers are on the lines with gradient > 1, the highest concentration of terms appearing on a line with gradient ~ 1.04. The uppermost of these lines appear to consist entirely of numbers with two or three distinct prime factors. See the attached images. It is conjectured that this behavior is true for all n. In the first 200000 terms the longest run of consecutive even terms is eight, beginning at a(7681) = 8078, while the longest run of consecutive odd terms is seven, beginning at a(101234) = 105471. It in unknown if these runs can be of arbitrary length. The sequence is conjectured to be a permutation of the positive numbers.

V3-016671 | OEIS-A373650

Integers k such that there are i groups of order k+i up to isomorphism, for i=1,2,3,4.

Conjectures (verified to 783 terms): If n = p-2 mod p, then n+2 = 2pm for some m, since n is even. Then if m > 1, one can show that this will always have 4 or more groups. Thus m=1 and n=2p-2. One must show that n can never be of the form 2p-2 if this conjecture is true.

V3-016702 | OEIS-A374258

Square array: T(n,k) = ((3^(n+1) + 1)^(k-1) + 2)/3, read by descending antidiagonals.

Conjecture: For each natural number n, the digits of the product of any (n+1) not necessarily distinct terms of the n-th row in the base (3^(n+1)+1) numeral system appear in nondecreasing order. Proof of the conjecture. Let b := 3^(n+1)+1. The product of any (n+1) terms of the n-th row has the form p/(b-1), where p is the product of (n+1) numbers of the form b^k+2. Let p = (dm, ..., d1, d0)_b, and we have d0+d1+...+dm = 3^(n+1) = b-1. Then p/(b-1) = (dm, ..., d2+...+dm, 1+d1+...+dm)_b, which do form a nondecreasing sequence. - _Max Alekseyev_, Jul 03 2024

V3-016745 | OEIS-A374913

Numbers k such that k^(k + 1) == k + 1 (mod 2*k + 1).

Conjecture (Superseeker): a(n) = A263458(n)/2. - _R. J. Mathar_, Aug 02 2024 The conjectured formula is false. There exist numbers k such that 2*k + 1 is composite and k^(k + 1) == k + 1 (mod 2*k + 1). For example, when k = 1023: 1023^1024 == 1024 (mod 2047) and 2047 = 23*89 is composite. - _Jedrzej Miarecki_, Jan 16 2025

V3-016746 | OEIS-A374916

Lexicographically earliest sequence of distinct positive integers in which any three consecutive terms are pairwise coprime whereas the squarefree kernel of their product is a primorial number (A002110).

6 cannot be a term in this sequence since if so a(i) = 6 would require Lpf(j) >= 5; contradiction. By similar arguments 10,15 and 30 are also not terms. Consequently no multiples of 6, 10, 15 or 30 are terms. 2,3,5 are the only prime terms and 1,2 are the only primorial terms. All terms are numbers divisible by one and only one of {2,3,5}, and the sequence is conjectured to be a permutation of such numbers, namely those congruent to (+ -){2,3,4,5,8,9,14}

(mod 30). Conjecture: As n approaches infinity all primorial numbers will eventually appear as rad(i*j*k).

V3-016747 | OEIS-A375006

Numbers whose Collatz trajectory is a Sidon sequence.

Hugo Pfoertner conjectured that the double of each odd term is a term, too. If this is true, then A375006 is the union of A374527, twice A374527, and A000079. Level-wise traversal of the corresponding subtree of the Collatz tree allows one to quickly generate many (unsorted) terms of the sequence. Up to at least level 1000 there is no counterexample to the conjectured occurrence of twice of all terms of A374527 in the present sequence. The results also suggest that A374527 is not finite.

V3-016751 | OEIS-A375178

a(n) = Sum_{k = 0..n-1} binomial(n+k-1, k)^3 (same as A112028 with an extra 0 at the start).

For prime p, binomial(p+k-1, k) == 0 (mod p) for 1 <= k <= p-1. It follows that a(p) == 1 (mod p^3) for all primes p. We conjecture that, in fact, the stronger congruence a(p) == 1 (mod p^5) holds for all primes p >= 7. Further, we conjecture that for r >= 2 and prime p >= 5, a(p^r) == a(p^(r-1)) (mod p^(3*r+3)). More generally, for a positive integer m, define a sequence {b_m(n) : n >= 0} by setting b_m(n) = Sum_{k = 0..n-1} binomial(n+k-1, k)^(2*m+1). Then the congruence b_m(p) == 1 (mod p^(2*m+1)) clearly holds for all primes p. We conjecture that the stronger supercongruence b_m(p) == 1 (mod p^(2*m+3)) holds for all primes p >= 2*m + 5, and for r >= 2, the supercongruence b_m(p^r) == b_m(p^(r-1)) (mod p^(3*r+2*m+1)) also holds for all primes p >= 2*m + 5.

V3-016786 | OEIS-A375925

Squares visited by a king moving on a walled, spirally numbered board, where a wall must be jumped on each move, always to the lowest available unvisited square.

However, it would be more natural to start the path at the origin, at a square labeled n = 0 (to which the king never moves). Then the sequence would conjecturally be a permutation of the nonnegative integers. This also leads to a more natural numbering for the squares in terms of the x,y coordinates - compare the Python function "square_number()". See A383185. (End) [Comment edited by _N. J. A. Sloane_, May 14 2025 following discussion with _Kevin Ryde_.]

V3-016790 | OEIS-A376084

Number of cryptarithmically unique primes with n decimal digits.

It is conjectured that a(n) is asymptotic to A006879(n) as n->oo based on the combinatorial probability estimate under the assumption that asymptotically for large n, the fraction of primes among integers that share a given digit pattern would be the same as among all integers with n digits, given by p(n)=1/(n*ln10) according to the prime number theorem. Since the number of integers sharing the same digit pattern cannot exceed 9*9!, the probability for a randomly chosen prime of length n to be cryptarithmically unique >= (1-p(n))^(9*9!-1), which is asymptotic to 1 as n->oo. The following terms are conjectured based on the assumption that at these lengths A374238 does not contain terms with 4 or more distinct digits, which follows from the vanishing probability of such terms estimated with combinatorial arguments: Further conjectured terms: a(20)=125975, a(21)=180471, a(22)=852579. - _Michael S. Branicky_, Oct 16 2024 lim_{n->oo} a(n)/A006879(n)=1 (conjectured).

V3-016797 | OEIS-A376238

Sequence obtained from A376239 by deleting the substrings of k-1 copies of k starting at index k(k-1)/2 + 1 for each k > 1.

In A376239 we conjecture that the sequences S[r+1] = D S[r], starting with S[1] = A376239, will have the property P(r) for all r >= 1. Here D means to delete the subsequences of k repeated k-1 times, starting at index (k-1)r + T(k-2) + 1, for all k > 1. The property P(r) means that for all k > 1, the sequence has k-1 copies of k, starting at index (k-1)r + T(k-2) + 1, and each of these runs is preceded by r smaller terms. (Thus, r is the number of 1s preceding the first 2 in the sequence.)

猜想/问题提及段 | historical_or_current_mention_unreviewed | _M. F. Hasler_, Oct 28 2024 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016798 | OEIS-A376239

a(n) = index k of the column in which n is found, if the columns k = 1, 2, 3, ... are initially filled with numbers T(k-1)+1, ..., T(k) = k(k+1)/2, and when n is found in column k, then the top element of each subsequent column (k+1, k+2, ...) is moved to the top of the previous column (k, k+1, ...).

Conjecture: Starting with S[1] = A376239, if S[r+1] = D(r) S[r] for all r >= 1, then each sequence S[r] has the property P(r). Here we denote by D(r) the operation of deleting the substring of k-1 copies of k starting at index (k-1)r + T(k-2) + 1, for all k > 1, and keeping only the intermediate chunks of length r. By property P(r) we mean that for each k > 1, the sequence contains k-1 consecutive terms equal to k, starting at index (k-1)r + T(k-2) + 1, each such run being preceded by r terms < k.

V3-016824 | OEIS-A376511

a(1) = 2. For n > 1, if a(n-1) is a novel term, a(n)=A001414(a(n-1)), else if there are k (>1) occurrences of a(j) = a(n-1) (1<=j<=n-1), a(n) is the smallest novel m such that A001414(m) = k*a(n-1).

Row n of table T(n,k) in A064364 lists numbers j such that A001414(j) = n, with T(n,1) = A056240(n), and every term in this sequence is taken from the appropriate row of A064364. When a(n-1) is a novel term a(n) = A001414(a(n-1)), which is defined. Otherwise a(n) = smallest m such that A001414(m) = k*a(n-1), a number which is also defined since it is the smallest unused term in T(k*a(n-1),k) of A064364. Therefore the sequence is well defined and infinite. Conjecture: For any n > 1 every term in T(n,k) of A064364 appears eventually.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016843 | OEIS-A377027

a(1) = 1. For n > 1, if a(n-1) is a novel term, a(n) = a(a(n-1)), and if a(n-1) seen k (>1) times (including a(n-1)), with k*a(n-1) < n then a(n) = k*a(n-1); else a(n) = 1.

The clause requiring a(n) = 1 if k*a(n-1) >= n is necessary to ensure continuation of the sequence, since without it there would be occasions of a(m) = a(a(m)) where a(m) is not yet defined, see Example. This is conjectured to occur infinitely many times as the sequence extends, which then implies that every positive integer will eventually enter the sequence (by incrementation of 1 if not before). Consequently every integer is conjectured to occur infinitely many times.

V3-016848 | OEIS-A377096

G.f. A(x) satisfies [x^(2*n)] A(x)^(5*n) = -5 and [x^(2*n+1)] A(x)^(5*n+2) = [x^(2*n+1)] A(x)^(5*n+3) for n >= 1.

The g.f. A(x) of this sequence satisfies similar conditions, with the surprisingly simple formula [x^(2*n+1)] A(x)^(5*n+2) = (5*n+2) * Product_{k=1..n} (5*k + 3) for n >= 1, a conjecture which has been verified for the initial 1001 terms. Compare with A377097, the dual of this sequence. (3) [x^(2*n+1)] A(x)^(5*n+2) = (5*n+2) * Product_{k=1..n} (5*k + 3) for n >= 1 (conjecture).

V3-016852 | OEIS-A377157

a(n) = n for n <= 3; for n > 3, a(n) is the smallest unused positive number that is coprime to a(n-1) if a(n-1) is prime and coprime to a(n-2) if a(n-2) is prime, else a(n) shares a factor with a(n-1) and a(n-2) if both are composite.

The fixed points begin 1, 2, 3, 6, 32, 57, 119, 343, 3123, 3859, 120481. The sequence is conjectured to be a permutation of the positive integers.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Scott R. Shannon_, Oct 18 2024 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-016853 | OEIS-A377182

Lexicographically earliest infinite sequence of distinct positive integers such that, for n > 2, a(n) shares a factor with a(n-2) mod a(n-1) while a(n-1) mod a(n) has not previously occurred as the mod value for any consecutive pair of terms.

Surprisingly the first prime to occur is a(94122) = 47857. The next is a(103105) = 26591, and no other primes appear in the first 500000 terms. It is unknown if more occur or why it takes so many terms for a prime to appear. Many small primes, like 5, can never occur as all mod values less than the prime have already appeared. It is conjectured all missing numbers are prime.

V3-016905 | OEIS-A379044

a(1) = 1, a(2) = 2. For n > 2 a(n) is the smallest positive integer k, not already a term in the sequence, such that A053669(k) = A006530(a(n-1)).

The terms of the sequence can be extracted from the table in A125703, where the k-th row gives numbers whose least non divisor prime p is the k-th prime. From a(5) onwards the first appearance of q = Gpf(a(n-1)) = prime(k) gives a(n) = A002110(k-1), the first term in the k-th row of A125703. Subsequent appearances of same q selects a(n) from the same row. The primes q = Gpf(a(n-1)) decrement from term to term if rad(a(n-1) is in A002110, and occasionally we see a full cycle of q from some higher prime terminating at q = 2 (see Example). However this is rare, because of interruptions when rad(a(n-1)) is not primorial, causing q to increment before decrementing again. This retards the arrival of odd numbers in the sequence. Whereas we may suppose that all numbers in A125703 will eventually appear, the blocking of full decremetation cycles of q produces a "firewall" effect opposing this possibility. Conjecture: Full cycles of decrementing q conclude with a(n) a power of 2 (producing the next odd term).

V3-016917 | OEIS-A379240

Lexicographically earliest infinite sequence such that a(i) = a(j) => f(i) = f(j), for all i, j, where f(n) = [A003415(n), A085731(n)] if A359550(n) = 1, otherwise f(n) = n.

It is conjectured that this is also the lexicographically earliest infinite sequence such that a(i) = a(j) => A003415(i) = A003415(j), A085731(i) = A085731(j) and A376418(i) = A376418(j), for all i, j >= 1, i.e., the restricted growth sequence transform of the triple [A003415(n), A085731(n), A376418(n)]. This is true if for every pair of i and j for which i <> j, and A376418(i) = A376418(j) > 0, the ordered pairs [A003415(i), A085731(i)] and [A003415(j), A085731(j)] differ from each other. In other words, conjecture claims that for all x, y in A100716, when x != y, either x' != y' OR gcd(x, x') != gcd(y, y') OR A376418(x) != A376418(y). If the conjecture 2 given in A399369 holds, then it implies the above claim as well. Adamczewski's AI-assisted disproof of the above conjecture in the linked arXiv-article (e.g., in versions 1-2, August 2026) is incorrect because it was based on a misinterpretation of A-number A376418.

V3-016934 | OEIS-A379505

a(n) is the number of ways of partitioning the divisors of n into two disjoint sets with equal sum, when an extra 1-divisor is added to the divisor set, and the two 1-divisors are considered indistinguishable.

Conjecture 1: For all n >= 1, a(A156942(n)) > 0. Also, if a(A156942(n)) > 1 is true for all n, it would imply that there are no quasiperfect numbers, numbers x with sigma(x) = 2x+1, as such numbers must all reside in A156942 and have a(x) = 1. (See references in A336700). Conjecture 2: a(n) = 1 if and only if n = 2^k, with k >= 0. This claim is equal to the statement that there are neither quasiperfect numbers nor almost perfect (least deficient) numbers, numbers x with sigma(x) = 2x-1, others than those given by A000079.

V3-017026 | OEIS-A381044

Primes prime(k) followed by a gap, prime(k+1)-prime(k), smaller than the local geometric average gap between consecutive primes: log(prime(k))/e^(gamma).

It has been conjectured that primes are distributed around their average spacing in a Poisson distribution (cf. D. A. Goldston and A. H. Ledoan). This is the basis of the conjecture that, for k tending to infinity, the asymptotic limit of the average of log(prime(k+1)-prime(k)) is log(log(prime(k))) - gamma (where gamma is Euler's constant). Also, the geometric mean of the gap between consecutive primes [p(k+1)-p(k)] is equivalent to log(prime(k)) / e^gamma.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017044 | OEIS-A381457

Integers encoding the recursive structure of a bitonic sorter network of n elements in their binary expansion.

A bitonic sorting network for n = 2^k elements requires (n/2)*(log_2(n))*(log_2(n) + 1) comparators (Batcher, 1968). This sequence extends the construction to arbitrary n by padding to the next power of 2 and pruning redundant comparators. The validity of this generalization as a sorting network remains conjectural; proofs are sought.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017047 | OEIS-A381464

Lexicographically earliest positive integer sequence satisfying a(n) = a(a(n))/n.

While extending the sequence at a(k) we will check if k equals a previous term in the sequence. If such a term a(m) = k is found a(k) is determined as a(k) = a(m)*m. If no previous term matches k we may choose a(k) = k+c with the least c such that c > 0 and k+c does not equal any previous term in the sequence. It is conjectured that this check is sufficient. Reasoning behind this conjecture: The greatest common divisor of two consecutive Fibonacci numbers is 1, thus we know that (k-1)^F(m)*k^F(m+1) and (t-1)^F(n)*t^F(n+1) are all different for some m,n > 1 if k and t are chosen such that for m or n < 2 no solution for (k-1)^F(m)*k^F(m+1) = (t-1)^F(n)*t^F(n+1) exist, because this cannot be equal if (k-1)*k and (t-1)*t have different prime numbers as divisors and if the only difference is the exponent of the prime factors, then the distribution of these between (t-1) and t and thus their progression F(n) or F(n+1) is individually distinct. In this sequence we need also to consider the more general case (k-c)^F(m)*k^F(m+1) = (t-1)^F(n)*t^F(n+1) because sometimes we need to set a(k) = k+c. It is conjectured that in this case c is bounded to be < 3.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017094 | OEIS-A382655

Lexicographically earliest sequence of distinct positive integers such that if m = a(n-1), a(n) is the smallest novel number k such that: g = gcd(m, k) > 1, m/g > 1, k/g >1 and gcd(m/g, k) = gcd(k/g, m) = 1.

The relation described in Name between two distinct numbers m, k refers to what may be described as "symmetric non-coprimality" (expressed as m # k), which in this sequence requires that if a(n-1) = m is a term, then a(n) = k is the smallest novel number such that m # k. From the definition it follows that 1, primes and prime powers cannot be terms in this sequence, however powerful numbers which are not prime powers can be terms (see Example). Sequence is conjectured to be a permutation of A024619. For two numbers m, k symmetrically related in this way we may write (m # r) = 1, and if the relation is not symmetric we may write (m # r) > 1. a(n) --> n as n-->00.

V3-017107 | OEIS-A383111

Number of integer partitions of n having more than one permutation with all distinct run-lengths.

A partition is Look-and-Say exactly when its distinct-part multiplicities m_i admit pairwise-disjoint strict partitions P_i of m_i (A239455). A valid word gives such a family from its run lengths. Conversely, choose such a family minimizing K = Sum_i |P_i|. If P_i = {r_1 < ... < r_k} and k > 1 + (K-k), then K <= 2k-2. The k values r_1,...,r_k and the k-1 sums r_j+r_k (1 <= j < k) are 2k-1 distinct integers because each sum exceeds r_k and the sums differ with j. Exactly K values are used globally and all r_1,...,r_k are used, so some sum r_j+r_k is unused. Replacing r_j,r_k by this sum preserves m_i, strictness and disjointness but lowers K, a contradiction. Thus |P_i| <= 1 + Sum_{h != i}|P_h| for every i. By the standard gap criterion, the block labels can be ordered with unequal neighbors; assigning these lengths yields a valid word. This proves the conjectured converse in A239455.

V3-017163 | OEIS-A383922

a(n) = A002104(n) + A002104(n+1) - 1.

Junyan Xu gives a conjecture on the recursive formula of m(x), where x + m(x) is the least fusible greater than x. (A188545(n) is -log_2 m(n)). We have m(x) = m_0(x) for x < 33/16 (i.e., F_0 and F coincide on the interval (-oo,33/16]), but they differ for x >= 33/16, even if the intersection of F and (-oo,n) still has order type omega^^n if the conjecture is true. In fact, we have -log_2 m_0(3) = 1541023937, while -log_2 m(3) > 2^^^^^^^^^16 in Knuth's up-arrow notation.

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017168 | OEIS-A384149

Irregular triangle T(n, k) in which row n gives the 2-densely-aggregated composition of sigma(n).

From empirical evidence of the first 1000 rows, reinforced by some known related properties, it looks readily credible that if we take the average of row n and its reversal we get A237270 row n, a palindromic composition of sigma(n) that was defined using Dyck paths. Row lengths are therefore conjectured to be in the database as A237271. T(n,k) = A384226(n,k) * A038712(n) = A384226(n,k) * A000203(n) / A000593(n). (conjectured). - _Omar E. Pol_, Apr 13 2026

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017172 | OEIS-A384228

Numbers k such that 128 * 3^k - 1 is prime.

Conjecture: This sequence intersects with A388408 at k = 2 to form twin primes with center N = 2^7 * 3^2 = 1152 = A027856(9). Any such intersection has to be at an odd k because if k is even, N-1 will be the difference of two squares, so not prime for N > 4. A covering system can be constructed that eliminates all other intersections (see linked program), and the search up to k = 250000 makes the probability of another intersection vanishingly small.

V3-017232 | OEIS-A386424

Numbers k such that sigma(k) has the same powerful part as k has, where sigma is the sum of divisors function.

Conjecture 1: the initial 1 is the only square in this sequence, and a(2) = 2 is the only term that is twice a square. Conjecture 2: A323653 is a subsequence (which would follow from conjecture 1 (c) given there). Conjecture 3: The only common term with A387727 is 1. - _Antti Karttunen_, Sep 12 2025

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Antti Karttunen_, Aug 17 2025 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017233 | OEIS-A386425

Odd composites k such that sigma(k) has the same powerful part as k, where sigma is the sum of divisors function.

By definition, the sequence contains all odd perfect numbers, and also includes any hypothetical odd triperfect number that is not a multiple of 3 (see A005820 and A347391), and similarly, any odd term of A046060 that is not a multiple of 5, etc. If there are no squares in this sequence (see conjecture in A386424), then the latter categories of numbers certainly do not exist, and this is then a subsequence of A228058.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Antti Karttunen_, Aug 17 2025 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017234 | OEIS-A386430

Odd numbers k such that there are no prime factors p of sigma(k) such that p does not divide A003961(k) and the valuation(k, p) is different from valuation(sigma(k), p), where A003961 is fully multiplicative with a(p) = nextprime(p), and sigma is the sum of divisors function.

Conjecture: After the initial 1, and apart from any hypothetical odd perfect numbers, all other terms are in A248150, i.e., sigma(k) == 0 (mod 4). This would imply (with the same caveat), that this sequence has no common terms with A228058 and no squares larger than one. This is true at least for the first 709203 terms (terms in range [1..2^34]).

V3-017244 | OEIS-A386642

Roll n fair, distinguishable, n-sided dice and sort the dice in increasing order with the lowest on the left, highest on the right. Let m be the maximum value rolled and select the m-th die from the right. Then a(n) is the number of such rolls (over all n^n possible outcomes) where the selected die shows 1.

Let p be the probability that the selected die shows 1; i.e., p = a(n)/n^n. Jameson conjectured (2025) that the limiting value of p is between 0.46 and 0.47. Tim Large conjectured (2025) that the limiting value of p is 1 - exp((1/e) - 1) = 0.4685.... Conjecture: a(n) = Sum_{k=1..n} ((n-k+1)^n - Sum_{j=0..k-1} binomial(n, j)*(n-k)^(n-j) - (n-k)^n + Sum_{j=0..k-1} binomial(n, j)*(n-k-1)^(n-j)) + 1.

V3-017249 | OEIS-A386671

All integers k that can produce a closed walk in a square lattice via noncongruent primitive k-length hypotenuses, in ascending order.

Other series with their own such patterns occur with a series based on (29 * 61 * 89) * p beginning at a(30) = 787205, and another based on (13 * 109 * 229) * p beginning at a(60) = 1622465. It is conjectured that there are infinitely many of such series. It is conjectured that all terms are products of 4 or more Pythagorean primes, including at least 4 different ones, though not all such products produce closed walks. It is also conjectured that all walks have an even count of hypotenuse segments and a minimum of 6 segments, and are bilaterally symmetrical when arranged in order of increasing angle.

V3-017251 | OEIS-A386760

Numbers k such that the number of decimal digits of the Lucas number L(k) is greater than the number of decimal digits of the Fibonacci number F(k).

The difference in the number of decimal digits, A055642(L(k))-A055642(F(k)) = A060384(k)-A386758(k) is either zero or one. In fact, this difference is ceiling(beta-{k*alpha}), with alpha and beta as defined in the Formula section. This implies that, asymptotically, a fraction of beta=0.349485... of the Lucas numbers has one more decimal digit than the corresponding Fibonacci number. This gives the asymptotic behavior of the sequence as a(n)~n/beta. Conjecture: abs(a(n)-n/beta)<c, for some constant c.

V3-017280 | OEIS-A387112

Numbers with (strictly) choosable initial intervals of prime indices.

Conjecture: Also numbers whose weakly increasing prime indices y satisfy y(i) >= i for every index i. The conjecture above is true. Reordering the intervals does not affect the existence of a system of distinct representatives, so let y(1) <= ... <= y(z) be the weakly increasing rearrangement of the x_i. Then the intervals {1,...,y(i)} admit distinct representatives if and only if y(i) >= i for every i. Indeed, if y(i) >= i, choose i from the i-th interval. Conversely, if y(k) <= k-1 for some k, then the first k intervals are all contained in {1,...,y(k)}, which has at most k-1 elements, so distinct representatives are impossible by the pigeonhole principle. The same argument also proves the corresponding conjectures in A238873, A387118, and A388711. - _Clément Garrot_, Aug 31 2026

V3-017284 | OEIS-A387186

Numbers k such that m!*k is a perfect square for some m < k-1.

Is a subsequence of A388851. Conjectured by Erdős and Graham to be the dominant component of that sequence (see also Erdős problem #374).

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Terence Tao_, Sep 22 2025 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017285 | OEIS-A387197

Numbers k such that 32 * 3^k - 1 is prime.

Conjecture: This sequence intersects with A387201 at k = 4 to form twin primes with center N = 2^5 * 3^4 = 2592 = A027856(10). Any such intersection has to be at an even k because if k is odd, either N-1 or N+1 has to be divisible by 5. A covering system can be constructed that eliminates all other intersections except where k = 4(mod 60), and for k > 4 with k = 4(mod 60), the search up to 10^5 makes the probability of another intersection in this residue class vanishingly small.

V3-017312 | OEIS-A387759

Lexicographically earliest infinite sequence of distinct positive numbers such that, for n > 2, a(n) shares a factor with a(n-1) and is coprime to a(n-2) if a(n-1) < a(n-2), else it is coprime to a(n-1) and shares a factor with a(n-2) if a(n-1) > a(n-2).. Start with a(1) = 1, a(2) = 4, a(3) = 9.

Of the terms studied there are no fixed points other than the first, and it is likely none exist. The sequence is conjectured to contain all positive integers other than the primes.

V3-017313 | OEIS-A387760

Numbers k such that 64 * 3^k - 1 is prime.

Conjecture: This sequence intersects with A387761 at k = 1 and k = 7 to form twin primes with centers N = 2^6 * 3^1 = 192 = A027856(7) and N = 2^6 * 3^7 = 139968 = A027856(11). A covering system can be constructed that eliminates all other intersections (see linked program), and the search up to 250000 makes the probability of another intersection vanishingly small.

V3-017315 | OEIS-A387852

The final prime number in the base n sequence when starting from 2 and creating the smallest unused prime number, when read in base n, by either removing or adding a single digit, from 0 to n-1, anywhere in the base n value of the previous number. If the base n sequence does not terminate, a(n) = -1.

It is conjectured that the sequence of primes in base n terminates for all n.

V3-017321 | OEIS-A388012

Numbers k such that sigma(k)/k >= 5/3.

It is not known whether sigma(k)/k = 5/3 for any k, so conjecturally, these are all numbers k such that sigma(k)/k > 5/3. However, if such a k exists, then it must by necessity be an odd square that is a multiple of 3, but not a multiple of 5 (and thus in A388016). Furthermore, 5*k is then an odd perfect number. See theorem 3 in Weiner paper.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Antti Karttunen_, Sep 13 2025 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017322 | OEIS-A388268

Numbers k for which A000005(k) >= A017665(k), where A000005 is the number of divisors function, and A017665 is the numerator of the abundancy ratio, sigma(k)/k.

After the initial 1, conjectured to be a subsequence of A023196. Note that for deficient numbers, k in A005100, we always have gcd(sigma(k),k) <= A032742(k), but not necessarily A000203(k) > A000005(k)*A032742(k).

V3-017336 | OEIS-A389105

a(n) is the smallest value of k such that gcd(A381466(k-1), k) = n.

We conjecture that a(n) > 0 for all n; i.e., every positive integer is a divisor in A381466 at least once; indeed, we conjecture that every positive integer is a divisor infinitely many times. For positive values found so far, a(n) > 1.2^(n-1), and we also conjecture this is always true.

猜想/问题提及段 | historical_or_current_mention_unreviewed | _Sam Chapman_, Mar 11 2026 | 2026-10-24

关键词命中原段；序列定义见题名及原页面 | 原始来源 | CC BY-SA 4.0

V3-017337 | OEIS-A389106

Least positive integer k such that A386395(k*n) has the least possible number of digits.

It appears that one can indeed achieve a minimal final length of 2 digits if n is a multiple of 10, and of 1 digit in all other cases. When n has an even number 2m of trailing zeros, multiplication with n/100^m yields a starting point equivalent to n/10^m, so it is sufficient to consider just one or zero trailing '0's. More generally, multiplying by the squarefree kernel f of n yields a starting point equivalent to sqrt(n*f) <= n with equality iff n is squarefree. Thus, no nonsquarefree n can be the first counterexample to the question/conjecture. - _M. F. Hasler_, Sep 24 2025

V3-017397 | OEIS-A390457

a(1) = 1 thereafter a(n) = floor(k(n)^n) where k(n) = a(1).a(2)a(3)...a(n-1) = 1.111... is the decimal digit concatenation of all preceding terms.

It is conjectured that a(n) = floor(k^n) where k = lim_{n->oo} k(n), which would be a constant k formed from its own powers. This conjecture fails if some floor(k^n) > floor(k(n)^n) due to k > k(n), but this seems unlikely since arbitrary decimals after k(n) would be a difference k^n - k(n)^n roughly equal to (n+1)*k(n)^n / 10^L(n) where L(n) is the length of k(n) after its decimal point, and that difference is small and rapidly decreasing.

V3-017406 | OEIS-A390793

Number of ways to write n as x^4 + y^2 + 2*z^2 + (p-1)^2/2, where x,y,z are in the set {m >= 0: 2*m is practical}, and p is either 1 or an odd prime.

Conjecture: a(n) > 0 for every natural number n. We have verified a(n) > 0 for n <= 4*10^5. As 2*z^2 + 2*w^2 = (z+w)^2 + (z-w)^2, the conjecture is stronger than the author's previous refinement of Lagrange's four-square theorem which states that each natural number can be written as x^4 + y^2 + z^2 + w^2 with x,y,z,w integers. The conjecture that a(n) > 0 for every natural number n is false. The following values of n have a(n) = 0: 3670016, 7864320, 12058624, 14680064, 15728640, 16252928, 19398656, 20447232, 22020096, 24641536, 28573696, 28835840, 30408704, 31457280, 32505856, 48234496, 49283072, 55574528, 58720256, 63963136, 65011712, 66060288, 74448896. These were verified by exhaustive enumeration of the equivalent representation n = x^4 + w^2 + 2*y^2 + 2*t^2, where x,w,y are nonnegative integers such that 2*x,2*w,2*y are practical numbers, and t = 0 or 2*t + 1 is prime. - _Scott Moore_, May 21 2026

V3-017431 | OEIS-A391602

a(n) is the largest number m such that A391449(m) = n.

a(0) through a(2) computationally verified to m = 2*10^14 (A141399 verified a(0) to 2.29*10^25). We conjecture this is sufficient to justify the finality of a(0) and a(1), and likely the finality of a(2). See the distribution of delta values by running the Octave_Deltas.c program at the attached link. Conjecture: All polynomial generator functions of order 2 or greater, G(n), with integer roots, and that are not perfect powers, are bounded in prime-complete numbers (A055932). Consequences: Since primorials are prime-complete by definition and verification shows no primorial products m*(m+1) for 715 <= m <= 633555, this suggests (714, 715) is the last pair of consecutive integers with primorial product. For Brocard's equation n! + 1 = m^2, since factorials are prime-complete and n! = (m-1)*(m+1), note that for odd m, (m-1)*(m+1) = 4*k*(k+1) where k = (m-1)/2, and delta(4*k*(k+1)) = delta(k*(k+1)) (multiplying by 4 just adds more powers of 2). Thus prime-complete (m-1)*(m+1) requires delta(k*(k+1)) = 0. Since a(0) = 633555 is the last k with delta(k*(k+1)) = 0, the bound m <= 1267111 (the final term of A194099) closes the search for solutions to Brocard's equation.

V3-017438 | OEIS-A391716

Let f be an additive function with f(2^e) = (e + e mod 2)/2, f(p^e) = e*(p-1)/2, p an odd prime. a(n) is the number of iterations of f(n) required to reach 0.

Every n appears a finite number of times in this sequence. Let S_n be the set of numbers k such that a(k) = n. We can prove that S_n is finite by an induction on n = 1, since S_1 = {1} as k = 1 is the only k such that f(k) = 0, and thus a(k) = 1. Let the induction hypothesis be that S_i has a maximum element M_i for all 1 <= i <= n. If r is in S_{n+1}, then f(r) is in S_n. We will prove that if f(r) = M_n, then r <= 2^(2*M_n). We note that for an arbitrary prime power p^e, f(p^e) = e*(p-1)/2 >= log_2(p^e)/2. Let r be composite. Then f(r) = M_n = Sum f(p^e) >= (Sum log_2(p^e))/2 = log_2(r)/2. Hence log_2(r) <= 2*M_n, and r <= 2^(2*M_n). Since f(2^(2*M_n)) = M_n, therefore 2^(2*M_n) is in S_{n+1}. If t is in S_{n+1} and t > 2^(2*M_n) and f(t) < M_n, then log_2(t)/2 <= f(t) < M_n. But then log_2(t) < 2*M_n and t < 2^(2*M_n), which contradicts the assumption. Consequently if t is in S_{n+1} and f(t) < M_n, then t < 2^(2*M_n). Therefore 2^(2*M_n) is the maximum element of S_{n+1} and S_{n+1} is finite.

V3-017439 | OEIS-A391736

Square array read by descending antidiagonals: A(n, k) is the value of quotient A048720(n,i)/i for the k-th odd number i which divides A048720(n,i), where A048720 is carryless base-2 multiplication.

The number of distinct values that may occur on row n of this array is at least 1+A115861(n), and at most n, because A(n, k) <= n. We conjecture that 1+A115861(n) gives the exact value.

V3-017441 | OEIS-A391775

Discriminants of totally real quartic fields in which every additively indecomposable element is a unit.

It is an open problem whether this sequence has infinitely many terms. All known terms correspond to totally real quartic fields of the form Q(sqrt(A + B*sqrt(D))) with D = 3 or 5. A special case of a conjecture of Siu Hang Man [Man 2024, Conjecture 1.7] states that there are only finitely many real biquadratic fields in which every additively indecomposable element is a unit.
